PUMPS, Compressed-Air. During recent years much progress has been made in the art of pumping water by compressed air. At first all methods of lifting water or other liquids by means of compressed air were deemed extravagant, but the development of various systems has been such that water may be pumped with marked economy and rapidly by compressed air. The direct-acting piston or plunger pump, of simple or duplex type, is operated with little economy with steam as a motive power. One hundred and fifty pounds of steam per horse power per hour is a fair figure to take for this machine. Experiments have shown that under average conditions hardly 50 per cent of the indicated horse power of the driving cylinder is utilized in the pump cylinder, the rest being absorbed partly by the engine as machine friction and particularly by the friction of the water in passage through valves and chambers.

Compressed air is utilized in pumping in two distinct ways, (1) as the motive power in power driven pumps; and (2) directly upon the liquid in displacement pumps.

Power Driven Pumps.—The advantage of the power driven pump over the displacement pump lies in the fact that it permits the expansive use of the compressed air, resulting in a considerable saving and economy. Power pumps consist essentially of expansive air engines, which may be either directly connected, belted or geared to some form of duplex or triplex piston or plunger pump, or to the simple, compound or turbine types of centrifugal pump in its various forms. Compressed air is supplied to the air engine from some more or less distant air compressor and this air engine, when specially designed for the use of air involving considerations of air valves and low clearance, operates with efficiency and economy. Where the magnitude of the operation justifies it, the use of the "return pipe" system with expansive engines will, in connection with reheaters, secure the very highest efficiency.

This type of pump consists essentially of two parts, an air end and a water end. The compressed air operates a piston which transmits its energy through the piston rod which, in turn, causes the pump piston or plunger to reciprocate and thereby pump water. In the "return pipe" or "closed circuit" system, the same air is used over and over again, the exhaust from the pumps being piped back to the compressor under a limited back pressure. In this case the compressed air is a transmitter of

power just as a belt or transmission rope, but the air never wears out, may be carried to any distance and at any angle, has little inherent friction and possesses the highest efficiency in transmission. The system eliminates all trouble from freezing since the air is used repeatedly and moisture once removed cannot be returned. While it requires two pipe lines instead of one, the pipe cost is frequently less because of the smaller pipe size permitted. The pump cylinders may be smaller because of the higher effective pressure per square inch and the losses in clearance, often enormous, are entirely eliminated. The great economy in this system is secured in the higher compression, since the scheme is based upon the well-known fact that the greatest losses in compression are thermodynamic, which losses are suffered chiefly at the lower pressures. For example 13.42 horse power will compress 100 cubic feet of free air per second to 60 pounds pressure, starting at atmospheric pressure. This same energy will compress 100 cubic feet of air to 350 pounds, when beginning compression at 60 pounds, giving on the return pipe system 290 pounds available pressure with 60 pounds back pressure. A reheater on the pump will secure additional economy. Losses through leakage and transmission are supplied by a small "booster" compressor. Where the pressure is above 60 pounds two-stage pumps are employed; where above 300 pounds, three-stage pumps.

Another method of securing high economy is to employ compound or triple expansion pumps, reheating the air after each expansion. This may reduce the air consumption to $\frac{1}{2}$ or $\frac{1}{3}$ its volume in the simple pump of the same capacity. In some cases this same result may be secured by the use of three pumps in series, reheaters being used as before after each expansion and the exhaust from one pump being supplied to the next, with a larger air cylinder.

Displacement or Pneumatic Pumps.—The displacement pump is almost the essence of pumping simplicity and, if its first promises had been borne out, it would be a most powerful factor in pumping problems. As it is, within its recognized field, it has shown a fitness which qualifies it especially for the work. In brief, it consists of two chambers or cylinders which are filled and discharged alternately—the liquid in each chamber being directly displaced by the admission of the required volume of compressed air through a valve operating automatically.

The fundamental requirement is a complete

submergence of three to six feet, or the setting of the chambers in a dry pit at a level so much lower than the water to be pumped that the chambers may fill rapidly by gravity. The filling is done at no expense of power and the discharge with a minimum of friction losses. Dirt, sand or grit will not interfere with its operation. Such a pump starts and stops automatically and uses air exactly in proportion to the amount of water discharged. It will run for weeks without attention and requires practically no repairs. Standard sizes have capacities up to 1,500 gallons per minute.

The height to which these pumps will lift water is limited only by the air pressure used, and by an arrangement of several pumps and reservoirs in series or steps almost any height may be attained with ordinary moderate air pressures. In mine work the displacement pump is especially useful in handling water accumulating in sumps, dips, entries, etc. It is also peculiarly effective in subways and tunnels, in automatically discharging the seepage or leakage water which accumulates. It may also serve in the basement of factories and warehouses which are subject to occasional inundations by floods or high water. Another very important economic use is the lifting of sewage from low-level catch-basins into the trunk sewer at a higher level. The same apparatus, but in modified form, is employed for elevating acids and heavy chemical solutions or for pumping marl, paints and other semi-fluids. In this case the air valve is so located that it is not affected by contact with the liquid or by corrosive fumes arising therefrom. The capacity of the displacement pump is determined by the size of the cylinders or chambers and the volume of air available. Employing air at ordinary pressure from a common single stage air compressor with a lift not exceeding 250 feet, the efficiency of the displacement pump is higher than that of the usual reciprocating plunger pump under the same conditions of lift and pressure. There are three distinct types of these pumps known as the Latta-Martin, Halsey and Harris or "return-air."

The Latta-Martin system employs two tanks, side by side, with a valve arrangement to convey compressed air to a point near the bottom of the eduction pipe. The air pipe is connected with a compressed-air reservoir on the surface, which is in or near the engine room in which free air is compressed. Before turning on the air the conditions in the well show water at the same level on the outside and inside of the eduction pipe. At the first operation we must have sufficient air pressure to lift to the surface the column of water which stands in the eduction pipe. This goes out *en masse*, after which the pump assumes a normal condition, the working air pressure being then lowered to stand at a point corresponding with the normal conditions in the well. This is determined by the volume of water which a well will yield in a certain time and the elevation to which the water is discharged. It was first supposed that in all air-lift cases the water was discharged because of the aeration of the water in the eduction pipe due to the intimate commingling of air and water. Bubbles of air rising in a water column not only have a tendency to carry particles of water with the air, but the column is made lighter, and, with a

submergence or weight of water on the outside of the eduction pipe there would naturally be a constant discharge of air and water. This is known as the Frizell system and where the lifts are moderate, that is, where the water in the well reaches a point near the surface, it is very likely that the discharge could be effected by simple aeration.

Most air-lift propositions are deep-well cases, that is, the water is lifted a distance greater than 25 feet. Aeration will not suffice to expel such water, so the idea of piston-like layers of expanding air alternating with blocks of water is developed. The upward urge of the air to reach the lower degree of pressure in the atmosphere and thus restore its equilibrium as free air carries or impels the blocks of water ahead of it to the discharge gate where separation takes place, the air escaping into the atmosphere and the water flowing away in the conduit provided. The economy of the air-lift system is in direct proportion to the capacity of the well to form these piston-like layers and the reason why they are formed is after the first discharge there is kept up a constant struggle between the air under pressure and the head of water on the outside of the pipe, each one seeking to enter the lower end of the eduction pipe.

When the air pressure is greater than that due to the head of water, a certain volume of compressed air is admitted into the eduction pipe. If a sufficient quantity of air has been admitted in proportion to the diameter of pipe, and if there is a sufficient pressure in this pipe to prevent the free discharge of the air, it is readily seen how this bubble of air spreads itself across the diameter of the pipe in a piston-like condition. The reason why this piston is not elongated and continuous is that the free discharge of the air, aided by the velocity with which everything in the eduction pipe is moving, causes a fall in the air pressure just sufficient to allow the water head to press the water into the open end of the eduction pipe. In other words, as the air pressure is for the moment slightly lower, the water pressure which was nearly equal to the air pressure, becomes a little greater and the piston-like layer of water enters the pipe, shutting off the air. This "chunk" of water rises in the eduction pipe with a velocity equal to that of the rising bubble of air and as it has plugged off the air nozzle, there is a momentary rest, during which the air has a chance to accumulate greater pressure, and just controlling the admission and discharge of water and air. In operation the pump is completely submerged and one cylinder fills by gravity while air is forcing out the water from the other. When this cylinder is empty, the air is automatically released, escaping into the atmosphere, and the water enters, the compressed air meanwhile being applied to empty the other cylinder. The discharge water flows continuously.

The Halsey system employs either a single tank or double tanks, as desired, and must be submerged to insure good operation. The tank fills by gravity, and as the water enters it causes a float to rise, which, when near the top of the tank, drops a valve and permits the influx of compressed air to discharge the water. The flow of water is intermittent with the single tank, but continuous with the double tank. Neither the Latta-Martin nor the Halsey sys-

tem uses compressed air expansively, and as a result there is considerable energy lost through the escape of the compressed air into the atmosphere—as with the high-pressure steam engine.

The "return-air" system overcomes the difficulty of not employing air expansively and in it no floats and no air valves, outside the engine room, are employed and the same air is used over and over again, thus eliminating the effect of clearance. This system employs two tanks and its operation consists in brief of pumping air out of one tank and forcing it into the other, and in so doing will draw water into the former and force it out of the latter. The content or volume of air in the system is so adjusted that when one tank is empty the other is full, and at that moment the switch will be automatically thrown, reversing the pipe action and thereby reversing the action of the tanks.

Figure 1 presents a conventional diagram of the displacement type of compressed-air pumps, drawn in this instance to show the action of the Harris or "return-air" pump. The air is being pumped out of chamber A and into chamber B, the water from which is passing up the discharge-pipe D, under the pressure exerted by the air on the surface of the water in B. When chamber A is full the valves on the air-pump reverse automatically and the air is pumped into A and out of B, the valves in the inlet box below the chambers reverse their positions and the water is forced out of A into the discharge-pipe, and a new charge of water

is tripped by an interior float when the chamber is full. The same trip opens the air valve and allows the compressed air to enter, driving the water before it into the discharge-pipe. With both these systems the air escapes into the atmosphere instead of returning to the compressor.

Of all systems of pumping the Harris is certainly the most economical and efficient.

FIG. 2.

FIG. 3.

Using the air expansively, all the inherent energy of compressed air is used, and no mechanism being submerged, there is no chance for the system to become inoperative due to breakage or a demand for repairs. This system may be employed for pumping mixtures of sand and water, and operates with a marked degree of economy and reliability.

Air-Lift.—Opinions differ as to the theory of the air-lift. A common air-lift is one where we have a driven well in which the water is comparatively near the surface. We place in this well a pipe for the discharge of the water. This is known as the "eduction pipe." This pipe does not touch the bottom of the well, but is lifted above it so as to admit freely the water through its lower end. Alongside this pipe, either on the outside or within, is a second but smaller pipe, properly proportioned; as soon as this pressure overcomes that of the water, the conditions are reversed and another "chunk" of compressed air is discharged into the pipe, shutting off the water for an instant. This process is continuous and as regular as the movement of a pendulum.

As these "chunks" of air approach the surface they are gradually enlarged, because of the reduced load upon them, and it is likely that before they reach the surface there is a general breaking up of the piston-like layer condition.

Figure 2 illustrates the action of the deep-well Pohlé air-lift, where the pressure of the air has to be relatively high. The pipe F leads the air from the compressor to the foot of the eduction pipe E. Where the diameter of the eduction pipe is properly proportioned to the weight of the column of water to be lifted, the compressed air pushes out of the air-pipe in little pledgets, one after another, holding their piston-like shape across the diameter of the

FIG. 1.

is sucked from the reservoir into B as the air content is exhausted by the air-pump. This diagram explains equally well the action of the Latta-Martin and the double-tank type of the falsey pumps—supposing only that the chambers of the two last mentioned are submerged so deeply in the reservoir that they fill naturally by gravity through a valve in the top which

eduction pipe, and each lifting its little load of water toward the free air at normal atmospheric pressure above. Where the lift is not so high and the weight of the water column not very great, the air is released at the bottom of the eduction pipe in bubbles, perhaps from several orifices at once, as in the Frizell system, and thus the water is aerated, rendering it so light that it flows freely upward with the air hastening to escape into the lower pressure above.

The differential air-lift operates with a comparatively low air pressure, and by using the air expansively achieves a considerable lift. The device consists of two (or more) air chambers, with the general arrangement shown in the explanatory diagram, Figure 3. It is to be supposed that the compressed air is being pumped into chamber A, exerting a pressure which forces the contained water upward through pipe G into chamber B. When the level of the water in A has sunk below the open end of pipe D the supply of compressed air is automatically shut off, and the compressed air then in A expands through pipe D into chamber B, there exerting a pressure which opens the valve at the foot of pipe F, up which the water contained in B is then forced. It is readily seen that the air pressure in B (supposing the chambers to be of the same dimensions) will be half that in A. If there is in the series a third chamber (C) of the same size and arrangement of pipes and valves, the air pressure in C will be one-third of the original pressure pumped into A. The possible lift from B to C will, of course, be just half that from A to B. Upon the final escape of the air at the top of the lift, chamber A fills with water by gravity and the cycle is renewed. A certain substantial amount of water pressure is necessary to smooth working of the air-lift. This is commonly secured by deep immersion of the eduction pipe. Where this cannot be secured an auxiliary air chamber is installed from which the air is pumped, the water flowing in to fill the vacuum as in the ordinary suction pump. On reversing the air, pressure is exerted downward on the water in the auxiliary chamber, thus forming an artificial "head" sufficient to lift the air-shaft.

The Pohlé system of air-lift is probably the best known. Sand, grit and small stones are no obstacles in the satisfactory operation of this system. As a matter of fact, in many instances the capacities of the wells have been increased by opening up the well more thoroughly through this removal of the sand. Water pumped by this system is purified to some extent—more so in the Frizell system—by the aeration. The system is not limited as to the quantity of water that can be handled. This will depend upon the capacity of the wells to furnish the water. The height of the lift is limited only by the degree of pressure imparted to the air. Consult Greene, A. M., Jr., 'Pumping Machinery' (New York 1911); Ivens, E. M., 'Pumping by Compressed Air' (New York 1914).

PUMPS AND PUMPING MACHINERY. In the modern acceptance of the term, a pump is a machine for exerting mechanical action upon fluids. It is commonly employed for raising liquids to a higher level; for propelling

them through pipes and orifices under (hydraulic) pressure; and for the compressing and rarefying of gaseous substances. The pumps used for compressing gases are discussed under the title AIR COMPRESSORS; those for rarefaction under AIR-PUMP and VACUUM-PUMP.

Pumps operate by two quite distinct methods, and are consequently classified as (1) suction or "bucket" pumps and (2) force pumps. The suction pump depends for its operation upon the constant pressure of the atmosphere—14.7 pounds per square inch. The action of the pump is to release from this pressure that area under the influence of the pump's piston: the

FIG. 1.—Section View of Modern Suction Pump.

air pressure outside of that area causes fluids affected by it to flow into the space in which the pressure has been diminished. In the force pump the force is applied directly by the pump mechanism to the fluid to be moved, regardless of atmospheric pressure. In its simplest form, the modern atmospheric or suction pump consists of a cylinder (c) connected at the bottom with a pipe (p), the lower end of which is immersed below the surface of the water. In the cylinder are placed two valves (uv and lv), the lower stationary and the upper attached to a piston (f) at the end of a rod (r), which moves the piston up and down under the motion of a handle (h). A pipe or spout (s), attached to the cylinder near its upper end, receives and discharges the water raised by the working of

the piston. Both the valves open upward, and the action of the entire arrangement, based upon the physical fact that two bodies cannot occupy the same space at the same time, is as follows: When the downward stroke of the handle moves the piston upward, the air in the space *A* is rarefied, having to occupy a greater space, and the partial vacuum thus formed relieves the pressure of the atmosphere from the lower valve, which being opened upward by the pressure of the air in the space (*B*) of the pipe, allows a portion of it to pass into the space (*A*). When the piston descends under the upward stroke of the handle, the air in the space (*A*) is compressed, the lower valve is closed, and when the density of the compressed air becomes greater than that of the atmosphere, the upper valve is forced open and the air passes into and out of the space (*D*). Thus, by the continued up and down movement of the piston, all the air in the space (*B*) is completely exhausted, the water rising in the suction pipe under the pressure of the atmosphere upon its surface in the well, until it fills the space (*B*) up to the lower valve. The next upward movement of the piston empties the air in the space (*A*), which is immediately filled with water by the opening of the lower valve. The downward motion of the piston relieves the pressure and allows the lower valve to fall into its seat. The water then in the lower part of the pump flows through the valve in the piston into the space (*D*), from which it is discharged through the spout by the next upward movement of the piston which at the same time refills the space (*A*) by suction. Under the laws of fluid pressure discovered by the experiments of Torricelli and others, the height to which a column of water will rise depends upon the atmospheric pressure at any point on the earth's surface, and varies with the altitude of that point. At the level of the sea, the atmosphere exerts a pressure of 14.7 pounds to the square inch, and will support a column of water in a closed tube from which the air has been exhausted, between 33 and 34 feet in height, while upon the top of Mont Blanc, or Pike's Peak, 15,000 or 16,000 feet above the sea, the atmospheric pressure will support a similar column of water only about 16 or 17 feet in height. A knowledge of this fact is important not only in determining the maximum distance at which the lower valve of a pump may be placed from the surface of water to be pumped, but also in every branch of hydraulic engineering in which atmospheric pressure is utilized.

By far the greater amount of pumping done in the economic world is accomplished by force pumps. It is, however, generally the case that the principle of the suction pump is used in combination to a greater or less degree, atmospheric pressure being relied on for preliminary lifts not to exceed 16 or 18 feet above the basic water level.

Force pumps are of two general types: (1) the piston pump, and (2) the plunger pump. In the former a well-fitted piston is driven to and fro in a smoothly-bored cylinder to which the water to be pumped is admitted. The pressure of the moving piston upon the water forces it out of the cylinder by any valve opening freely outward, and thus into pipes through which it may be raised to heights varying with the power exerted on the piston; or it may

transmit the pressure of the piston to all water in a long pipe line for power purposes. The plunger pump is similar in results, but develops its pressure by the forcible thrusting of the comparatively large mass of the plunger into a chamber already filled with water. The water being incompressible, a volume of it equal to the bulk of the entering plunger is driven out

FIG. 2.

of the chamber into the transmission pipes. Both piston and plunger pumps are usually designed to act both on the outward and the return strokes—the piston sucking in a supply of water behind it as it moves in either direction; and the plunger being double-ended, and working alternately into two chambers divided by a wall or a diaphragm carrying a packing ring or sleeve. These types are known as double-acting pumps. In the sectional diagram of a piston force-pump shown in Fig. 2, the piston *P* is represented as starting on its outward stroke. The water *W* before it is being forced upward through valve *E* into the discharge-pipe system *D*, while valves *F* and *K* are

FIG. 3.

held shut by the internal pressure. Valve *H* in the supply-pipe system opens by "suction," and the supply water flows in behind the advancing piston. On the return or inward stroke,

valve F opens for the discharge of the water which has just come through H, and valve K opens to allow the supply to again fill the cylinder. The same description applies to the diagram of the plunger force-pump, Fig. 3; in which P represents the plunger which drives outward and back alternately into chambers W and Y, divided by the packing-ring R, R.

A variation of the plunger pump is the "differential" pump, in which the valves and double-acting plunger are so arranged that while suction of the supply water takes place only on the outward stroke, a discharge occurs upon the strokes in both directions. Fig. 4

FIG. 4.

presents a sectional diagram of the most common form of the differential pump, in which P represents the plunger, working in the sleeve R, R. On the inward stroke just beginning, the water in chamber W is forced out into the discharge system D, valve K opening to allow a supply to be drawn in (by suction) through pipe S into chamber Y. On the return stroke valve K is closed by the pressure, and valve E opens, and another discharge into D occurs.

While there are undoubtedly a larger number of pumps worked by hand than by any other power, such pumps are relatively small, and are not operated continuously. By far the greater part of the world's pumping, as to volume, is done with what are called power pumps, many of them being very large. The power generally employed is steam, although compressed air is coming more and more into use, being found more economical. (See PUMPS, COMPRESSED-AIR). The attachment of the power to the pump has generally taken the tandem form, with the power cylinder at one end and the pump cylinder at the other, the piston rod of the steam cylinder being extended to form the piston rod or plunger rod of the pump. This type is known as the direct-acting pump. In other arrangements the steam cylinder may act upon a walking-beam to which the pump rod is connected; or it may work upon a shaft on which is a fly-wheel. Frequently the work is divided, two or three cylinders being provided for both steam and pumps, working alternately or in succession, and thus discharging a more nearly continuous and uniform volume of water. All of these power pumps discharge the water against a

cushion of air, the elasticity of which relieves pump, engine and piping of shocks which otherwise would soon be disastrous to their mechanism. These air chambers are, therefore, to be considered an essential part of the pump. They are proportioned to the volume of water delivered per minute, and the pressure which is to be preserved in the pipe line into which the water is delivered, a certain specific volume of air being necessary to transmit the particular pressures of the individual installation. In some makes of pumps air chambers are placed also on the suction pipe, to take up and distribute (in point of time) the strains of operation, aiding materially in maintaining a uniform discharge.

Rotary pumps, formerly in limited use, have become very numerous, as the electric motor offers an ideal power for small installations. These pumps are of two general types, called conventionally "piston" and "plunger." In the piston rotary pump the piston-rod carries longitudinal wings or vanes which produce a "wiping" pressure on the water in the cylinder as the piston revolves on its axis. The more modern types are fitted with two "pistons" set parallel, the wings of which interlock to prevent a backward flow of the water. They are run usually at great speed by small dynamos, and do excellent service in raising comparatively small quantities of water to the service tanks on the roofs of buildings of moderate height. The plunger type of rotary pump has a cylindrical plunger revolving on a

FIG. 5.—Sectional Diagram of Piston Rotary Pump. P, P, pistons revolving in opposite directions.

longitudinal axis placed eccentrically as to the plunger, but in the centre of a larger cylinder in which the plunger revolves. A longitudinal backstop, actuated by springs, or by its own weight, prevents the water crowded out of one-half of the cylinder from flowing back into the half whence it was forced by the plunger. Another form of rotary pump is the "screw" pump, a cylinder having a longitudinal centre shaft set with a series of blades like those of a screw propeller. This is sometimes called an "impeller" pump, and is of great utility in pumping sewage and similar heavy and heterogeneous liquid mixtures which could not be

moved by the forms of pumps commonly in use. One of the last-named type was constructed at Milwaukee in 1889 to flush the Milwaukee River of its sewage-polluted waters. It has a screw wheel 13 feet in diameter, which, revolving at a rate of 60 revolutions per minute, de-

FIG. 6.—Sectional Diagram of Plunger Rotary Pump. L, inlet; M, outlet; N, back stop; P, rotating plunger.

livers 550,000,000 gallons of water a day on a lift of four feet. This water is forced through a brick-lined tunnel 12 feet in diameter, and 2,500 feet long. A battery of 11 of these screw pumps are in use in New Orleans for discharging storm water from the city's drainage system. They are 12 feet in diameter and run at a speed of 75 revolutions per minute. The screw is placed at the summit of a flat-topped siphon and is operated by an electric motor. The discharge is about 550 cubic feet per minute, the height raised varying from five to nine feet. The efficiency of these pumps as shown by actual tests is 80 per cent.

FIG. 7.—Sectional diagram of centrifugal pump. I, inlet; R, rotor; D, diffusing chamber; V, volute casing; O, outlet.

The "centrifugal pump" is the best known representative of the "impeller" type. It embodies the principle — that a body revolving around a centre tends to move away from it with a force proportional to its velocity; thus the rim of a revolving wheel imparts a portion

of its velocity to any substance adhering to it, and throws it off when the force of the velocity thus imparted exceeds the force of adhesion, as the mud thrown off by the wheels of a carriage, or the water from a mop or towel, rapidly revolved by the hand. The first pump of this type was invented by M. Le Demour, who sent a description of it to the Academie Française in 1732. It consisted of a straight tube attached in an inclined position to a vertical axis, around which it was whirled by a crank-handle. Later forms were constructed by tubes joined in the form of a T, the vertical tube of which was placed in the water. The lower end perforated to admit the water, and fitted with a valve to retain the water in the vertical tube when the pump was not in operation, was placed under the surface of the water and supported upon a pivot. The ends of the horizontal discharge tube were bent down into a circular trough over which they were revolved. When the machine was revolved rapidly the centrifugal force which discharged the water in the horizontal tube was communicated to the water in the vertical, which was also drawn out, but in the meantime refilled by the atmospheric pressure on the reservoir. When it is required to lift large quantities of water to a low elevation, centrifugal pumps may be used with greater efficiency than reciprocating pumps, the efficiency of which diminishes with the lift. A pump of this kind, constructed in Massachusetts in 1818, was equipped with four blades set at right angles like those of a fan blower, and was used for many years. An improved form was exhibited by Appold in England, in 1851, which embodied all of the principal features employed in the best pumps constructed since that time. It is stated that Appold's pump raised continuously a quantity of water equal to 1,400 times its own capacity per minute. The "whirlpool chamber," designed to utilize the energy developed by the whirling water which in most pumps of this type is lost as eddies in the discharge pipe, was suggested by Thomson (Eng.), and consisted of a chamber somewhat larger than the pump, in which the water discharged by the pump disc, with considerable velocity, was allowed to rotate and impart its energy as an auxiliary aid to the driving power. A pump constructed by him for drainage purposes, in the Barbados, was equipped with a whirlpool chamber 32 feet in diameter, around a pump disc 16 feet in diameter. Others of large size were constructed by Easton and Anderson, for the North Sea Canal, in Holland, which were capable of delivering 670 tons of water per minute to a height of five feet; while the Gwynne pumps employed to drain the Ferrarese marshes in Italy, at the junction of the Po di Volano and the minor rivers of lower Lombardy, are capable of a combined delivery of 2,000 tons of water per minute.

A large class of pumps, involving the principle of centrifugal action in some degree are the turbine pumps.

The turbine pump is practically a reversal of the turbine water-wheel (q.v.), being a turbine run by power, generally steam, to produce motion or pressure in a body of water or other liquid. It differs from the centrifugal pump in adding the power advantage of the screw to that of centrifugal force. A common application of this form of pump where the lift is

high and the pressure heavy is to place these pumps in series, the second taking its supply water from the first, and so starting its work with a considerable degree of pressure; the third pump taking water from the second, and so on. As many as 10 of these turbines may be thus combined to form the "ten-stage" turbine pump. By this means the load is distributed, the velocities of the rotors being transmuted into pressure in the diffusing chambers. These multi-stage turbine pumps are used in the equipment of fire-boats, which are required to deliver great volumes of water at high pressure.

The injector and the pulsometer are also classified as pumps, though operating on prin-

FIG. 8.—Sectional View of Pulsometer.

ciples quite different from those exhibited in the machines more familiarly known under the title of "pump." The injector is described in detail in a special article (see INJECTOR). The pulsometer consists of two bottle-shaped chambers (a) and (b), the tapering necks of which incline toward each other in a common passage at (c). At the lower end of this passage is a valve (d), which when moved slightly will simultaneously close the opening of the neck of one chamber, and open that of the other.

Water is admitted into the chambers through the passage (e), and valves (f) (g) and forced out through the valves (h) (i), and passage (j) into the air chamber (k). The device operates as follows: Suppose both chambers are full of water and the valve (d) to the right. When steam is admitted to the chamber (a) the water is forced out by direct pressure through the valve (h) into the air chamber (k), so that when the chamber (a) is nearly or quite empty, the valve (d) moves to the left, cutting off the

steam from the chamber (a) and admitting it to the chamber (b), from which the water is gradually forced out. In the meantime the condensation of the steam in the chamber (a) creates a partial vacuum, and the pressure of the atmosphere on the external water forces it through the valve (f) into the chamber, so that when it is nearly full, the air it contains will be sufficiently compressed to force the valve (d) over to the right, thus producing a continuous action. The efficiency of pulsometers is equal to that of small direct-acting feed pumps, and they are extensively used on account of their simple construction and great durability. Nearly allied to the injector and pulsometer in point of the physical action involved is the "explosion," or "internal combustion" pump—a typical example of which is the so-called Humphrey gas pump. It consists of a chamber

FIG. 9.—Sectional Diagram of Double-cylindrical "Humphrey" Type of Gas Pump.

(A) in which an explosive mixture of air and vaporized gasoline is admitted through the valve (V). This mixture is exploded by an electric spark, and the expanding gases press downward upon the water in the chamber (B), forcing it out through the pipe-line (P), and into the reservoir (R) and up the standpipe (D). When the force of the gas has expended itself the escape valve (E) drops in the reduced pressure, and the burned gases pass out before the return surge of the water standing in the standpipe (D). Meanwhile, in the low pressure prevailing, the inlet valves (I) open and admit water from the basin (K), which pours into chamber (B) until the returning water from the pipe-line brings pressure enough to close them, and also the exhaust valve (E), and opens the gas valve (V) by a float. A backward surge of the water, in coming to an equilibrium, sucks in a charge of gas through (G), and the vibrating water comes back once more and compresses the gas, at which juncture it is fired; and the cycle is repeated indefinitely. It will be seen that one delivery of water covers four vibrations in the pump. This leisurely action has been reduced to half the time by connecting two pairs of chambers to the suction pipe, so that the first resurge after firing compresses the gas charge in the second gas chamber, and fires it, each resurge thus being sent forward as a discharge. The largest of these gas pumps in America is a 66-inch pump in irrigation service at Del Rio, Texas, delivering 28,000 gallons per minute at a height of 38 feet.

"Impulse pumps" are those operated by the impact of a falling column of water or by the force of a moving column of water suddenly arrested, or by jets of steam, compressed air,

or water under high pressure. The hydraulic ram is an example of the first group. It was originally designed by Whitehurst, a watchmaker of Derby, England, in 1772, and subsequently perfected by Montgolfier, the famous French balloonist, in 1796. It consists of a supply pipe (a); an air-chamber (b) attached to the upper side of the pipe (a), and fitted with a valve (c) at the pipe opening; a valve (d) at the end of the supply pipe, and a vertical pipe (e), opening freely into the air-chamber, through which the water is raised to the desired elevation. The device operates as follows: The valve (d) is made just heavy enough to drop and open the lower end of the pipe (a) when the water filling the pipe is at rest. Now assume that this valve opens, allowing the water in (a) to run out. This water gradually acquires an increasing momentum, which finally carries the valve up against its seat and closes the outlet. The water in

FIG. 10.—Sectional View of Hydraulic Ram.

(a) is thus brought suddenly to a state of rest and a part of it rushes into the air-chamber (b) through the valve (c). But, the instant the water in (a) is again in a state of rest, the valve (d) drops again, opens the outlet, allows the water to run out, and is again closed when the increasing pressure is strong enough, bringing the water again to a sudden halt and forcing some more of it into the air-chamber, thence by the elasticity of the air cushion (b) to be pushed upward through the pipe (e) to the point of delivery—and thus the cycle is continued. The action of the valve (c) prevents the return of the water from the air-chamber to the pipe (a). This device is adapted to numerous locations and will operate automatically and continuously, without any attention whatever, so long as the surface of the water at the source of supply is kept at the same elevation so as to insure a uniform pressure against the valve (d). When the perpendicular distance from the source of supply to the valve (d) is small, and the water is required to be raised to a comparatively great height, pipe (a) must not only have a considerable fall but must be of larger diameter, and be of sufficient length to prevent the water from being thrown back into the source of supply by the shock when the valve (d) closes. It is also necessary to maintain the supply of air in the air-chamber, which in time, under the great pressure, becomes depleted by being dissolved in the water. In small rams a sufficient amount of air enters through the valve (d), but in rams of considerable size a small "snifting valve," attached to another chamber immediately below the air chamber, automatically supplies the additional air whenever it is necessary.

Jet pumps operating with steam or compressed air are termed "ejectors." They are in use for spraying or atomizing liquids in

various manufacturing processes. The jet pumps operating with high pressure water are known commercially also as "eductors." They have no valves or other moving parts, and are not subject to wear and tear, and, being also of low first cost, are very economical where a small supply of high-pressure water can be commanded. The construction is extremely simple. The high-pressure pipe is placed in the centre axially of a larger flow or discharge pipe and fitted with a conical mouthpiece. The discharge pipe is narrowed at the opening of the jet and then expanded gradually to its full size. With a three-inch discharge pipe and a one and one-half-inch jet pipe operating with a pressure of 40 pounds to the square inch (about 90 feet head) the discharge will amount to 5,000 gallons per hour. For lifting water the pressure in pounds per square inch of the jet opening is made two and one-half times the elevation in feet. Thus if the lift is 20 feet the pressure required is 50 pounds. The eductor works well on the level of discharge if the suction lift is not more than 15 feet.

The so-called "high-duty" pumps are those in use for heavy work against great pressure. They include waterworks pumps, mine pumps, fire-service pumps, elevator pumps, hydraulic pressure pumps and the like. Practically all are direct-acting pumps operated by steam. They are built both in the horizontal and upright forms. One of the first American pumps designed for high-duty waterworks service was the "Worthington direct-acting duplex steam pump." It consists of two double-acting plunger pumps placed side by side with the piston-rod of each steam cylinder connected by a lever to the slide valve of the adjoining steam cylinder, so that the movement of each piston instead of operating its own slide valve, as in the simplex pump, operates the slide valve of the adjoining cylinder. The valve motion is so adjusted that just before the piston of one cylinder has finished its stroke, the piston of the other begins its movement. The load of the water column is then taken up alternately and produces a steady flow without serious strains, harshness of motion and noise, which characterize the action of the simplex pumps, in which the water column is started into motion at the beginning, and arrested at the end of each stroke of the piston. Although the simplicity of their mechanism, together with the cheapness of their first cost and the certainty of their action, placed them at the head of all the machines of their class, when considered from a mechanical standpoint, the loss of economy in the use of steam continued to militate against their general use for heavy duty purposes. Their light weight prevented the cutting off of the steam in the steam cylinder so as to complete the stroke of the piston by the aid of the expansive energy of the steam thus cut off. Therefore the steam applied to move the pistons had to be applied in sufficient quantity and pressure to overcome the weight of the water column and its friction through the pump and connections, at the very beginning of the stroke, and maintained without diminution throughout the stroke, up to its termination, since a falling off in either volume or pressure during any part of the stroke would have stopped the action of the pump instantly. This defect, however,

was completely eliminated by applying to them the principle of multiple expansion in the use of steam in compound condensing steam engines. Another steam cylinder was added to the end of the one already in use, and placed in a direct line with it so that the high pressure steam admitted to the first and smaller cylinder, after moving its piston, was exhausted behind the piston of the large cylinder upon its return stroke. Still further economy was produced in the larger compound engines by using a condenser to create a vacuum in the large steam cylinder, thus bringing the efficiency fully up to that of the best high-duty rotative engines of the most important pump-

rod which is extended for this purpose through the outer end of the pump chamber. On the end of this rod is fastened a cross-head which moves in guides attached to the outer end of the pump. On this cross-head, and situated opposite to each other, are two hemispherical recesses. On the guide plates are two journal boxes, one above and the other below the plunger-rod, equidistant from it, and placed at a point equal to the half stroke of the cross-head. Each journal box carries a short cylinder hung on trunnions, which allow the cylinder to swing in unison with the motion of the plunger rod. In these cylinders are plungers or rams, which pass through a stuff-

FIG. 11.—Sectional View of Worthington High Duty Pumping Engine.

ing plants of the world with yearly records ranging from a duty of 50,000,000 to 120,000,000 foot-pounds per 100 pounds of good coal.

The duty of the Worthington pumping engines was still further increased, and the entire arrangement, from the power-producing to the pumping ends, was made to represent the highest perfection of modern pumping machinery, by the application of the accumulator, a device originally invented by J. D. Davis, in 1879, and perfected by C. C. Worthington, in 1884. With it the steam may be cut off in the steam cylinder soon after the beginning of the piston stroke, a part of the power being stored and brought into play toward the end of the stroke so that the force exerted upon the pump plunger remains uniform through the entire stroke. In a compound direct-acting steam pump, the device is attached to the plunger-

ing box on the end. The outer ends of the rams have rounded projections which fit into the recesses on the cross-head, which is moved in and out with the plunger, thus tilting the cylinders backward and forward. These cylinders are called "compensating cylinders." When the engines are used for pumping water, they are filled with water, and when used for pumping oil, they are filled with oil. The pressure on their rams is produced by connecting the cylinders through their trunnions which are hollow, with an accumulator, carrying a ram which moves up and down as the rams of the cylinder move in and out. This accumulator is of the differential type, the small lower cylinder of which is filled with water or oil, in which the ram moves, while the larger upper cylinder is filled with air. On the top of the accumulator-ram is a large piston-head which

fits closely in the air cylinder. Therefore, the pressure per square inch on the accumulator-ram and also in the compensating cylinders is equal to the pressure of the air in the air cylinder per square inch multiplied by the difference between the area of the air piston and that of the accumulator-ram. It is a matter of calculation and construction, which varies according to the particular service for which a pumping engine is designed; while the pressure in the air cylinder is controlled by the pressure in the main delivery pipe with which the air chamber is connected. The effect of this attachment on the successful operation of high duty pumping engines may be briefly described as follows: At the beginning of the outward stroke of the pump plunger-rod, the compensating cylinders point inward toward the pump, with their rams at an acute angle with the plunger-rod, and op-

For the sake of economy in floor space most high-duty pumps are built in the upright or vertical form, the steam cylinders at the top, and the pump cylinders below. With the exception of the Worthington, which still remains of tandem design, the high, intermediate and low pressure steam cylinders are set side by side in a rank. With the same exception also, most of the high-duty pumps are built to work on a crank shaft carrying fly-wheels, some of which are enormously heavy; weighing, for instance, in the Holly waterworks pumps up to 32 tons each, and each pump carrying two such fly-wheels.

The term "duty" represents the work done by a steam pumping engine expressed in millions of pounds of water lifted to the height of one foot by the consumption of 100 pounds of coal, 1,000 pounds of dry steam, or by

FIG. 12.—Pumps and Pumping Machines.

posing its advance with the full pressure of the accumulator load. As the plunger-rod advances outward, the angle between itself and the ram is increased gradually to 90 degrees. The rams recede into their cylinders, and their pressure against the rod is decreased until the pump plunger-rod has reached the halfway point of its stroke, when the rams will be at right angles to it—a position in which they neither retard nor advance its movement. As the pump plunger-rod continues on its outward stroke, the angle between itself and the rams is again decreased, but now the rams, pointing in the opposite direction, emerge from their cylinders, and exert their power to push the plunger onward to the termination of its outward stroke. It is obvious that similar conditions obtain during the return stroke of the plunger, the effect of the action being to store up power during the early part of the stroke, either forward or backward, when the steam is under its greatest pressure, and to release it at the end of the stroke, when the pressure in the steam cylinder has fallen away to its lowest point, that is, below the amount necessary to move the plunger against the pressure of the water column.

The Worthington pumps with this attachment and the use of multiple expansion steam engines operate with absolute freedom from the noise and shock so characteristic of the crank and fly-wheel machines.

1,000,000 British thermal units (B. T. U.). On account of the variable quality of coal, the two last-named constants give the more correct results, and are the values now employed in determining the comparative efficiencies of pumping engines, which range from 20.6 per cent for the high-duty engines, to about 0.13 per cent for jet pumps. During the last 100 years, the development of pumping engines has increased their duty from about 5,000,000 foot-pounds for the Newcomen atmospheric engines, to over 170,000,000 foot-pounds for the crank and fly-wheel, or duplex triple expansion pumping engines of the latest construction.

Somewhat of an idea of the difference between the first duplex Worthington pumping engines and those of their latest construction may be obtained by comparing that of the Charlestown, Mass., waterworks, with its capacity of 5,000,000 gallons per day, with the installation at the Baltimore, Md., waterworks high service pumping station, which delivers 18,000,000 gallons per day. The former gave a duty of 70,000,000 foot-pounds, while the duty of the latter exceeded 140,000,000 foot-pounds per 1,000 pounds of dry steam.

Hydraulic pressure pumps are designed as a rule for driving water into an accumulator, whence it may be drawn for power service in mains, or for use in hydraulic presses (q.v.), hydraulic cranes (q.v.), and similar machines.

The pumps which do this exceptionally heavy work are of the plunger type of direct-acting pumps, the plungers being very small—about one and one-quarter inches in diameter and of six-inch stroke, while the steam cylinders are of the usual size. The high and low pressure cylinders are commonly placed side by side and work upon a crank-shaft which carries a heavy fly-wheel. These pumps work up to 4,000 or 5,000 pounds per square inch.

In all reciprocating pumps, valves play an essential part. In the simplest forms the valves are made of leather or rubber, and are fixed in position by a hinge on the edge, generally, for the larger sizes, having a metal form which prevents too great relaxing. They are made in a great variety of forms and operate in response to certain pressure, or, as in the case of the Reidler valve, by mechanical means. They consist essentially of a "valve seat," to which the "disc" or valve proper is attached, the "stem" which controls the lift of the disc and prevents its displacement from the seat, the "cover plate," and the "valve spring," introduced in some forms to take up slacks. When a valve is required only to prevent the back pressure or a reverse flow, a single flap or check valve is used. In large pumps a number of small valves are employed, equal in aggregate area to a single large valve of sufficient size to allow the passage of the whole flow, thus preventing injurious shocks when the valves are opened and closed suddenly, as all of the smaller valves do not close simultaneously but each as its critical pressure supervenes. Excepting the discs, all the other parts of a valve are made of bronze, while metallic ball and cone valves are extensively used in deep well pumps. A detailed description of the more commonly used valves will be found in the special article under the title VALVE.

History.—The raising of water for economical purposes dates back to the remotest periods. It is not easy to determine just when mechanical appliances worthy to be classed as pumps first made their appearance, and it has been the custom of some writers to dignify the common water-pail by the name of pump if only it were lifted by mechanical means—as, for example, with the old-time well-sweep. In this connection mention has been made of the "shadoof," of Egypt, authentically recorded as having been in use over 1,500 years B.C., in the time of the Pharaohs, a period antedating the Exodus. It is still used extensively in that region, myriads of them lining the banks of the Nile, where they are worked unceasingly by relays of men, without intermission, day and night. It is also used extensively all over Hindustan, where it is called the "picotah." In fact, the "sweep" in some form is used extensively in all of the Oriental countries from Asia Minor to China and Japan and also in Mexico and South America, for domestic purposes and for the irrigation of land. For the latter purpose, however, it was superseded in India by the "jantu," an oscillating wooden trough involving the same principle, that of the lever, and worked by hand. The "windlass and bucket" arrangements operated by cranks or by tread-wheels, the latter worked by men or animals, appear to have followed the "sweep," first among the Chinese, and later

among the earliest Greeks and Romans. About the beginning of the Christian Era, Vitruvius, a Roman engineer, described a number of pumping machines involving a rotary principle—the "tympanum," "noria," "chain of buckets or pots," the "screw" and the "pump." The tympanum consisted of a series of gutters with their open ends joined to a shaft hollow at one end and placed above the surface of the water at the height to which the water was to be elevated. The gutters thus arranged radially extended to a short distance below the surface of the water which they scooped up successively when the shaft was rotated. Each gutter as it passed above the horizontal position delivered its water to the shaft to be subsequently discharged through a trough at the desired point. This primitive device continued in use from the remote ages of antiquity up to the 18th century without any change of construction, when La Faye, a member of the Royal Academy of Sciences of France, improved it by substituting a series of curved canals for the original straight gutters, thus developing the progenitor of the "scoop wheel," which, propelled by streams, are extensively used for draining purposes. La Faye's improvement and the geometrical reasoning which developed it are exhaustively described by Belidor (Tom. ii, 385, 387). While the tympanum consisted of a series of revolving gutters, the noria may be described as a number of "sweeps" arranged around a central shaft like the spokes of a wheel, each carrying on its outer end a vessel which fills as the rotary motion of the shaft plunges it beneath the surface of the water, and subsequently discharges its liquid freight into a reservoir placed at the upper part of the circle. It is commonly known as the Persian wheel. The "chain of buckets or pots" was an elaboration of the simple bucket and cord arrangement, by the introduction of a pulley operating an endless rope or chain, to which several buckets or pots were attached. It was employed by all the foremost nations of antiquity, and is yet used in many parts of Europe and Asia. Among half-civilized nations it was the highest type of hydraulic machines. Sometimes, when the source of supply was a river, as in the case of the Persian wheels on the Orontes, the driving wheels of the arrangement were placed in the river and propelled by its current. About the middle of the 17th century, European mechanics recognized that when the water was admitted into the receiving vessels of a noria or a chain of pots at the upper part of the circumference, it was converted into an overshot wheel, thus affording a means of power transmission to other machines, and in cases where the water supply was limited, but descended from a considerable elevation, it was substituted for the overshot wheel as a prime mover in operating mining pumps, dredging, threshing and other machines of a similar character; while as a conveyor, originally used exclusively as a water elevator, it has also been employed to raise mortar in the construction of buildings, city walls and fortifications, and for carrying grain and flour to the different floors of a mill. In its original form, that of the "sakia" of Egypt, it was unquestionably the pump introduced into Greece by Danaus when he dug the wells of Argos, 1485 B.C., about a

thousand years before the building of Babylon by the Persians. Danaus was a brother of the Pharaoh Rameses, who resigned during the period the Israelites were in Egypt. He was compelled to leave that country on account of domestic troubles, and accompanied by his family and friends sailed for Greece. They landed on the coast of Peloponessus, and settled at Argos. According to Pliny (vii, 56), previous to the arrival of these Egyptians, the Greeks were unacquainted with wells and pumps; therefore, it is natural to conclude that the wells of Argos dug by Danaus were equipped with the Egyptian pumping devices most adaptable to wells, which was the chain of pots, and not a form of atmospheric or force pump, the pioneer of which is described in Hero's 'Spiritalia' as invented by Ctesibius of Alexandria, one of the most eminent mathematicians and mechanicians of that period, in the year 224 B.C. The most modern refinement of the chain of pots is the "chain pump," while Vera's "rope pump" and the hydraulic belt are applications of the same idea, and consist of endless double bands of rope or woollen cloth passing over two rollers, one placed below the surface of the water, the other at the point of delivery. The rollers are driven at a velocity ranging from one to two thousand feet per minute, and as the bands pass over the upper roller, the water held between them by capillarity is forced out by the pressure and discharged into a receiving chamber connected with the delivery spout.

Water-raising machines embodying the principles of the screw, stated by some authorities as invented by Archimedes, the Greek geometrician and greatest mathematician of antiquity, and by others credited to the genius of Canon of Samos, a contemporary of Archimedes, about the year 242 B.C., are described by Vitruvius as of Egyptian origin, and were, according to other authentic records, employed in Egypt, for draining and irrigating land, many centuries before Archimedes visited that country. It consists of one or more flexible tubes of lead or leather, wound spirally around a solid cylinder of wood or iron, the ends of which are pivoted to supports, so that the whole arrangement may be revolved upon its axis, which is generally placed at an angle of 45 degrees to the horizontal. The lower end of the tube is placed below the surface of the water, and the upper end over a receiving trough at the desired elevation. When the machine is rotated the water entering the lowest bend of the spiral is forced upward by each succeeding revolution into the other bends, and finally discharged out of the uppermost into the trough. The Roman screws were made with plank grooves arranged spirally around a solid cylinder, and the grooved cylinder thus constructed was fitted into and revolved within a hollow cylinder of the same length. Thus foreshadowing the turbine pump of the present day.

The connecting link between the various more or less elementary forms of water elevators or "lifts" already described, and the group of hydraulic machines designated as "displacement pumps," is the modern chain pump, consisting of a tube through which the water is raised by a series of pallets or pistons. The pump of Ctesibius appears to have been of this

character, although it consisted of only two single-acting pistons working in a cylinder, the water being raised by the up-stroke and expelled by the down-stroke, into a common receiving chamber. In this machine the atmospheric pressure was not taken into consideration, and its capabilities as a water-lifter remained unrecognized until 1643, when Torricelli, the great Italian physicist, announced that water could be raised in a tube by the pressure of air. In 1641, Galileo, when consulted by a Florentine pump-maker, had failed to demonstrate why water failed to rise in a closed tube above a height of 33 feet under the action of a suction pump. A year or two later, after the death of Galileo, Torricelli undertook the explanation of that fact, his experiments finally resulting in establishing the law that the heights attained by liquids in a closed tube, the upper end of which was a vacuum, under the pressure of the atmosphere, was proportional to their specific gravities. For example, under these conditions, the height of a column of mercury would be about 28 inches, while that of a column of water would be about 33 feet at the level of the sea. The direct result of this experiment was the invention of the siphon barometer, in which the empty space above the column of mercury is known as the Torricellian vacuum; but the further experiments of Pascal, a French mathematician and divine, in 1646, followed by those of Otto Guericke, a philosopher and mathematician of Magdeburg, Prussia, and of Candido del Buono, a member of the Academie del Cimento of Florence, led to the invention of the "air pump," an apparatus which is described under that title, and which must not be confounded with the atmospheric or displacement pump used for pumping water, which was not unknown to the ancients, and was probably used in some of its innumerable forms, long before the days of Ctesibius.

The expansive energy of compressed air, hot air and steam, was probably employed by the ancients as the motive power of pressure engines to raise water many centuries before the Christian era. There are extant numerous authentic descriptions of devices equipped with piston bellows, employed for this purpose by the ancient Egyptians, Hindus, Chinese, Peruvians and the Aztecs. Also descriptions of hot-air devices and pressure machines operated by steam, the majority of which were contrived by the members of the ancient priesthoods. A great many of these machines are described in the 'Spiritalia,' written by Heron, or Hero of Alexandria, a celebrated Egyptian mathematician and physicist, who lived in the 1st century A.D. The water-jet apparatus known as Hero's Fountain, although asserted to have been invented by him, was probably an old device at the time he described it. In either case, it is the oldest pressure engine ever described accurately in which a volume of air was used instead of a piston. In 1560 Baptista Porta, an Italian, published a work entitled 'Natural Magic,' in which he described a method of producing a vacuum by the condensation of steam, and its application to devices for raising water. Similar descriptions are given in the writings of Jerome Cardan, also an Italian, published some time between 1515 and 1570. Therefore, although nothing new was discovered by De-

caus, whose writings were published in Frankfurt in 1615 and in Paris in 1624, or by Fludd, Worcester, Savery and Papin, whose investigations and writings extended over the period from 1663 to 1698, the suggestions afforded by their experiments (subsequently elaborated by Freiburg in 1797 and Shone, Callon, Frizell and Pohlé in the period extending from 1870 to 1900) have led to the development of the various forms of modern air-lift pumps operated by compressed air and pulsometers operated by steam.

Although pressure engines operated by air compressed under a head of water, as suggested by Papin in 1695, had been employed successfully to drain mines as early as 1755, when Hoel employed one in the mines of Chemnitz, Hungary, the application of steam for that purpose did not become an accomplished fact until a much later period. It is, however, interesting to note that the idea was suggested by Lord Bacon prior to 1679, in connection with the English mines, and probably was practically applied to a limited extent about that time. The history of the modern pumping engine, however, more properly begins with the construction of the Cornish engine. Up to the close of the 18th century, the only practical use of steam engines was in connection with pumping devices, and many notable steam pumping engines had been erected and successfully operated in the mines of Cornwall, England. The various improvements made in this engine from 1800 to 1840 finally culminated in the evolution of one superior type which is now known as the "Cornish." This engine gave highly satisfactory service for the particular purpose for which it was designed—the raising of water out of deep mines where the constantly increasing depth of the shafts necessitated the adaptation of the same engine to the consequent increasing and changing loads. It is constructed upon the principle that the steam within the steam cylinder is used to lift a weighted pump plunger which after being raised upward to the limit of its stroke, descends slowly by its own weight and forces upward a column of water equal to that weight. The economy produced by the expansion of the steam in the steam cylinder when the steam is cut off during the descent of the plunger is due to the fact that the pressure and power of the steam first admitted is greatly in excess of what is necessary to lift the weighted plunger. This excess of power is taken up by the weights of the plunger at the beginning of its stroke and given out at the end when the power of the exhausted steam in the cylinder has fallen below the amount necessary to move the plunger, unless assisted by the power previously stored in it. The length of the stroke of the piston and of the plunger being determined solely by the operation of its steam, equilibrium and exhaust valves, it is absolutely necessary to maintain the steam pressure at a uniform rate, while the water raised must be received under a uniform head. In mine pumps the steam cylinder is placed at the top of the shaft, and the pump at the bottom, near the surface of the water. The steam piston is connected to the pump plunger by a beam made of heavy timbers, the weight of which, together with that of the weight of the plunger, forms the weight which, after being lifted by the steam

cylinder, raises an equal weight of water when the plunger descends.

In order to preserve the proper relation between the weight of the pump rods and plunger, and that of the water columns, and also keep the engine and pump at the proper speed, by maintaining the proper difference in the weight of the pump rods so as to overcome the friction of their guides, and that of the water in the delivery pipes, a large box, called the "balance bob," in which the adjusting weights in the shape of stones or pieces of iron are placed, is attached to the upper end of the pump rods. When the shafts become deeper and require the lengthening of the pump rods, the additional weight of the new timbers is counterbalanced by a readjustment of the weights in the "balance bob," thus adapting the engine to the new conditions. In its particular field of application, requiring only a slow action with no demand for continuous flow, it is safe to state that it has never been excelled by any other engine; but, its inordinate size, its action which requires the constant watchfulness of the engineer, its great first cost and expensive repairs, makes it unfit for waterworks, where the water has to be discharged through a long main to a great height above the pump, with a continuous and uniform delivery. The shortcomings of the Cornish engine, named above, led finally to its complete abandonment for waterworks, and called for a pumping engine that would fulfill the new requirements. This demand was met by the development of the "rotative" engine which, by employing revolving instead of reciprocating pistons, gave a positive motion. The steam power in the cylinder is applied to the pump piston in various ways—through the medium of long or short beams, bell cranks or gearing, and in some instances directly through the pistons themselves; in all cases, however, the limit of the stroke of the steam piston and of the pump plunger being governed by a crank on a revolving shaft. Attached to this shaft is a fly-wheel which is designed to assist the crank to pass the centre at each end of its stroke and also to give up at the beginning of each stroke of the steam piston the excess of power imparted to it beyond that required to move the column of water. The function of the fly-wheel of a rotative engine is exactly similar to that of the weighted plunger in a Cornish engine; both of the devices being applied to their respective classes of engines to obtain the best economy in the consumption of steam, the early cut-off resulting in a high grade of expansion, much higher than it was possible to obtain by any other means at the time. They vary greatly in design and in the details of construction, and are made in sizes ranging from those used for supplying water to small towns, up to some of the largest and most expensive machines in the world, and operate either vertically or horizontally. They produce great economy in the use of steam at the expense of intricate machinery, but require expensive and massive foundations to absorb the shocks produced by their operation, while the momentum of the fly-wheel greatly increases the percentage of possible accidents.

To follow further the progress of pumping-engine construction up to the invention and development of the "direct-acting steam pumps," which now represent the highest type of pump-

ing machinery, it is necessary to take up the historical thread in the United States. Although steam pumping engines of the direct-acting type, beginning with the device invented by Thomas Newcomen and John Cawley, of Dartmouth, England (which was subsequently improved by Watt, who developed it into an engine of the double-acting type), were in great use for many years; the greatest improvement in this class of pumping engines was made by Henry R. Worthington of New York in 1840. His invention was the outcome of a long series of experiments on the application of steam to the propulsion of canal boats. It was a single direct-acting steam pump and was employed to feed the boilers of his propelling engine, and was patented for the first time in 1841. Although steam pumps of this type came immediately into extensive use for feeding boilers and for supplying moderate quantities of water under medium pressure, the intermittent action of their pump pistons and consequent irregular flow of water prevented them from being used in waterworks and for other purposes where large quantities of water had to be forced through long lines of pipes. To overcome this serious defect the same inventor produced the improved pump which is now generally known by his name.

Revised by RICHARD FERRIS.

PUN, a play upon words alike or similar as to sound, but different as to sense. The pun has been familiar to all literatures, and in ancient times was used even in serious context. This was true also in England of the 17th and 18th centuries. Puns are met with in the tragedies of Shakespeare; in the works of the quaint Fuller; in the discourses of Bishop Andrews. The divines of colonial America did not lack for them. Mathey Byles won his reputation for wit chiefly through the appositeness and felicity of his puns. Thus, being a sturdy loyalist, he was for a time kept under surveillance by a sentinel whom he called his "observe-a-Tory." A parishioner called upon him and Byles, noting his ulcerated jaw, sent him to Copley, the artist, to have his tooth drawn. Among famous English punsters may be cited Sydney Smith, Lamb, Theodore Hook, Wilberforce and, above all, "Tom" Hood, most inveterate and happy of the coterie, who even remarked of a certain undertaker that he appeared anxious to "win a lively Hood." The pun has frequently been derided as an unworthy form of wit. John Donne is reported to have said that "He who would make a pun would pick a pocket"; and Holmes, in the 'Autocrat,' after denouncing verbicide, gives a pyrotechnic display of excellent puns. It is true, however, that the pun has found advocates in divines, philosophers, statesmen and literati. Many puns convey a weight of meaning which could hardly be secured by sentences of paraphrase.

PUNCH, a well-known English comic weekly, the most famous journal of the kind. The success of Philipon's Paris *Charivari* induced a staff of several Englishmen — some, as Douglas, Jerrold, Thackeray and John Leech, since famous — to organize for the publication of a *London Charivari*, of which whole pages of text had been set up, when the scheme collapsed. This undertaking had, however, some indirect influence on the subsequent *Punch*. The idea of *Punch* appears to have been due originally to Ebenezer Landells, a Northumbrian wood engraver and draughtsman, and to have been developed by Henry Mayhew, a brilliant humorist of the time. "Mr. Punch" was the traditional jester of the puppet-show transformed into "the laughing philosopher and man of letters; the essence of all wit, the concentration of all wisdom." As finally agreed, Mayhew, Mark Lemon and Stirling Coyne were to be coeditors, Landells was to find drawings and engraving, and Douglas Jerrold and Gilbert & Beckett were to be among the outside contributors. The first number appeared on 17 July 1841. In two days two editions, each of 5,000 copies, were sold out. After some early vicissitudes, *Punch* became an English institution. A list of its writers and artists includes many famous names besides the jovial Lemon and the caustic Jerrold; Thackeray, "Tom" Hood, Charles Lever, "Tom" Taylor, Cuthbert Bede, Horace Smith, Shirley Brooks, F. C. Burnand, Artemas Ward, G. A. Sala, H. W. Lucy, John Leech, H. K. Browne ("Phiz"), Sir John Tenniel, George Du Maurier, Stacy Marks, Sir John Millais, Linley Sambourne and others. The editors have been Mark Lemon, 1841-70; Shirley Brooks 1870-74; "Tom" Taylor, 1874-80; Sir F. C. Burnand, 1880-1906; and Owen Seaman, 1906—. *Punch* has done much to laugh out of court various shams, fads, affectations and forms of ostentation. In British politics it has remained wholly free from party bias. The present application of the word "cartoon" originated with *Punch*, the occasion being the first great exhibition of cartoons for the Houses of Parliament (July 1843), when Mr. Punch appeared with a rival series of sarcastic designs. Consult Spielmann, 'The History of "Punch"' (1895); 'An Evening with Punch' (1895), selections from the first 50 years; a Beckett, A. W., 'The a Becketts of Punch' (1903).

PUNCH, a beverage, commonly composed of wine or spirits, water, lemon juice and sugar, with occasionally an addition of some spice, as nutmeg or cinnamon. These are usually mixed in any desired proportions in a large bowl made for the purpose — hence called the punch-bowl. The beverage may be compounded as follows: Squeeze the juice out of three or four lemons, adding thereto the peel of one lemon cut in slices, 12 ounces of lump sugar and three and a half pints of boiling water; infuse this mixture for half an hour, then pour into the punch bowl, and add of rum and brandy rather less than a pint of each. Varieties of punch are called after one of their principal ingredients, gin, milk, orange, raspberry, tea, wine, etc. Punch was introduced into Great Britain from India, and it appears to be so called from the

Hindu *panch*, five, which is the usual number of the ingredients.

PUNCH. See METAL-WORKING MACHINERY.

PUNCH AND JUDY, in Great Britain and some European countries, a well-known puppet-show frequently exhibited in the streets. The show of Punch and Judy derives its origin from the Neapolitan Punchinello, but many of its features are purely English. The earliest account of the adventures of Punch and his wife, Judy, is found in a ballad, the date of which does not appear to be anterior to 1795. This account corresponds pretty closely with the representations given in our streets. The show embodies a domestic tragedy, followed by a supernatural retribution, the whole of which is treated in a broadly farcical manner. Punch himself is represented as short and thick-set, with an immense hump upon his back, a wide mouth, long chin and hooked nose, and wearing a three-pointed cap. His wife, Judy, who is in some respects his counterpart, and his dog, Toby, are important characters in the performance. See also PUPPET-SHOWS.

PUNCHEON, a liquid measure of capacity containing from 84 to 120 gallons. See WEIGHTS AND MEASURES.

PUNCHINELLO, pūn-chī-nēl'ō (from *pulcinello*), an Italian mask or marionette. The Abbate Galiani derives the name from a misshapen but humorous peasant from Sorrento, who had received it (about the middle of the 17th century) from his bringing chickens (*pulcinelle*) to market in Naples, and who, after his death, was personated in the puppet-shows of the San Calino Theatre, for the amusement of the people, to whom he was well known. See also PUPPET-SHOWS.

PUNCTUATION, from the Latin *punctus*, "a point," is the term used to designate the use of points, or marks, for the purpose of separating words from each other in sentences and parts of sentences. The convenience of such separation is obvious, yet for many centuries after writing had first been used there was nothing to indicate the pauses, or divide a book into sentences. No attempt to punctuate is apparent in the earlier manuscripts and inscriptions of the Greeks. It was in Alexandria that punctuation originated, when that city was the centre of ancient learning. The open space to the left of a line which indicates the beginning of a paragraph made its appearance on papyri at Alexandria. The early signs intended for punctuation were at first used in poetry only, to enable readers to comprehend the meaning hidden in obsolete words and involved and difficult verses. Ages passed, however, before any form of punctuation became general, and it was not until the 9th century after Christ that the division of sentences by period, colon and semicolon marks took place. The comma was the same as to-day, a large dot or double dot indicated the full stop, and a high dot stood for a colon or semicolon.

The following rules for the use of the points are condensed from De Vinne's 'Practice of Typography.'

The chief purpose of the comma is to define the particles and minor clauses of a sentence. Reversed, and often in pairs, commas mark the beginning of a quotation. A reversed comma

marks the abbreviation of Mac in Scotch names, as M'Carthy. Reversed commas in tables are a sign for ditto. The comma frequently supplies the place of omitted words, as in addresses.

The semicolon keeps apart the more important members of the sentence, and is most used in long sentences.

The colon is used after the particles or introductory words to another statement, as in to wit: viz: for example: Dear Sir: It is often used to separate hours from minutes, as 2:14, for 14 minutes past two.

The period marks the end of a completed sentence. It is also employed in abbreviations, as J. Smith, i.e., q.v., etc. It separates whole numbers from decimal fractions.

The dash has been substituted for almost all the points, being once much used to indicate suppressed words. It is employed to connect a side heading with the text that follows. It should be selected where there is an abrupt change in statement, as "Thus the plot thickens — but I weary you." It serves to give additional force to an anti-climax: "They will steal anything, and call it — purchase." The insertion of a comma before the dash is now regarded as unnecessary.

The parenthesis, usually shown in pairs, encloses the words added to a sentence, which would be complete without it. The bracket has similar uses, but is preferred when the words introduced are not by the author, but added as explanatory by an editor.

The interrogation marks the end of a question that requires answer. It is not needed when the question does not call for an answer, as "The Cyprians asked me why I wept."

The exclamation marks a word or phrase intended to express great surprise or emotion; and is used also at the end of an exclamatory clause. "Look, my Lord! it comes!"

The apostrophe, most used to mark the possessive case, as in John's, is used also to show the contraction of words, or omitted letters, as h'd'k' for handkerchief, I'll for I will, and the clipping of words in dialect, as nuthin' for nothing. It is also used to mark the close of a quotation, single or double. For all nouns in the plural number that end in s, the apostrophe must follow to make the possessive, as boys' games; singular nouns ending in s call for 's, as James's book.

The first function of a hyphen is to mark the division of a word that carries into the next line, but it serves also to connect compounded words, as round-shouldered.

Consult Wilson, 'Treatise on Grammatical Punctuation' (1850); Teall, 'Punctuation' (1899); Cochrane, 'Punctuation and Capitalization' (1908); Hart, 'Rules for Compositors' (Oxford 1912).

PUNDIT, or PANDIT, an Indian title for men who devote themselves to the pursuit of learning, especially on religious subjects. It corresponds with the modern title of "Doctor." It is especially applied to certain men who in the 19th century after being instructed by the English in the science of geodesy have explored and surveyed Tibet, and other areas of Asia generally inaccessible to Europeans. The most notable of them were Mohammed i Hamid, who went (1863-64) over the Karakoram Pass

to the Yarkand River; the famous Naing Singh, who, between 1865 and 1875, brought back valuable results from his travels in Tibet, and discovered the northern springs of the Indus; Mirza Sudja, who (1868-69) crossed the Little Pamir to Kashgar and Ley; Haider Schah, who in 1870 made an expedition to Faizabad in the valley of the Oxus, and later explored the mountain ranges between Cabul, Bokhara and East Turkestan. Consult Garbe, 'Indische Reiseskizzen' (1889).

PUNIC (pū'nik) **WARS**, in ancient history, the general name applied to three great wars between the Romans and the Carthaginians. The first (264-241 B.C.) was for the possession of Sicily, and ended by the Carthaginians having to withdraw from the island. The second (218-202 B.C.), the war in which Hannibal gained his great victories in Italy, was a death struggle between the two rival powers; it ended with decisive victory to the Romans. The third (149-146 B.C.) was a wanton one for the destruction of Carthage, which was effected in the last-named year. See CARTHAGE.

PUNICA. See POMEGRANATE.

PUNISHMENT, in the strict sense of the term, is a definite expression of public indignation, at least conventional, if not genuinely moral. It always aims, at least, at expressing the indignation of the social group, and in this resides the fact that it is only externally similar to the earlier custom of revenge which, theoretically, is private. Public indignation, like non-moral resentment, or revenge, is a reactionary state of the group consciousness directed toward the cause of inflicted pain or other injury. And even punishment is, as in the cases of blood-revenge, frequently indiscriminate. In these cases punishment not infrequently falls on the relatives of the culprit. The nature of punishment necessarily involves suffering in the form of pain or loss of honor, place, power, liberty, property or even life. It implies forfeiture of what would otherwise have been admitted to be a right inhering in the sufferer, who suffers because he has perpetrated a wrong. The common will is not, as Rousseau informs us, "the sum of the individual wills." The common will is the product of social life, and it is the will of establishing the solid foundations of peaceable interrelations among the members of a community. There being a stern necessity of social bonds under penalty of extinction to the whole community, the common will develops a most powerful tribal conscience demanding universal obedience to certain general rules called laws. All the citizens of a community may well be said to agree in this, that everybody regards himself as exempt; wherever there are laws all know there are some who will disobey them. The primary object of punishment is in every instance to maintain or restore the common will or social order. Our legal system in all its parts is a virtual confession of man's incapacity for individual self-government. "It is when a man can do as he pleases," says Huxley, "that his troubles begin." Statutory law is the will of a nation published in written and enduring form for the information of those subject to it. And yet after everything is done that can be done to instruct people as to what the public good requires, we always find two classes:

those who abide by the demands of the public will, and those who do not. How shall the state treat those who wilfully violate its statutes? What shall be done with those who are both mentally capable of understanding its demands and who are physically able to conform to them, but still act directly counter to their requirements?

Such questions have been asked since man became a member of society: and the answer given was, punish them, or "cure" them. Such was the origin of punishment. The advocates of this treatment of public offenders saw its justification in many principles. Some saw in punishment a vindication of the law; others protection (which too often is inspired, however, by mere revenge and forgetful of the fact that two wrongs do not make a right); "example" was the purpose of still others (but these not seldom revealed an inclination to ignore all sense of proportion, and the degree of guilt); a recent development is the idea of reformation. Of all the foregoing, the notion of making an example is perhaps the least worthy, being an (unconscious, it may be) expression of mere vindictiveness. It is alleged to be a deterrent theory. Could the infliction have any deterrent effect at all upon just people unless it was supposed that the person punished was receiving his actual deserts? Reflection will, we feel certain, teach anyone that punishment out of all proportion to the degree of guilt would have just the opposite effect upon the just if they thought otherwise.

In every society the traditional notions as to what is right and wrong, obligatory or morally indifferent, are all too commonly accepted by the great majority without any further reflection. At their source not a few of these notions have their origin (sociology shows this) in sentimental likings and antipathies. The moral estimate all too frequently survives the cause from which it sprung; and no enlightened judge could fail to see that while this is so, the operation of "example" as a punitive principle would lead to flagrant injustice, for many times the moral estimates that come down to us from our fathers have no foundation in existing conditions.

Considered etymologically the word punishment would, it was hoped, throw some light upon what was uppermost in the minds of its advocates through the ages. That etymology is as follows: Punishment derives from Old French *punir*, which in turn comes from Latin *punire*, to punish, from *poena*, punishment, expiation, pain; and this is from the Greek *ποινή* (*poine*), meaning quit-money or fine for blood spilled. The Greek word finds its cognate in the Sanskrit *Ki*, to repay, which is related to the Zendish *kitha*, penance, and *kana*, vengeance; these Aryan words are related to the Slavonic *cena*, a price. But valuable as these suggestions are one cannot expect, as Professor Wundt observes, to find much help from etymology; for "the phenomena of language do not admit of direct translation back again into ethical processes. The ideas themselves are different from their vehicles of expression and here as everywhere the external mark (or word) is later than the internal act for which it stands" (Wundt).

Remembering all this, it may not be far out of the way to admit that punishments should

be graduated according to the degree of harm of an offense to society and according to the attractiveness of the offense to the offender; and not out of a desire to set an example. Its intrinsic object is to remove the "sin" not the "sinner," but the cause of danger and of pain.

Punishment, in Western countries and nowadays, is seldom applicable to civil actions though these also are followed by compulsory payments of moneys, or failing this, by deprivation of property, liberty, etc. As the legal consequence of crimes, however, punishment consists chiefly of infliction of pain on the body; and this ranges from capital punishment, or death, down to imprisonment. In some instances whipping is added; and formerly in military and naval offenses, flogging. In crimes of lesser degree, imprisonment or penal servitude for a term of years is the punishment.

Since very early times a constant change in the treatment of punishment has been going on in civilized states. Its treatment may be divided into two parts; in the first place there is detection, arrest, trial and acquittal or conviction; in the second, treatment of the criminal after conviction. The acquisition by the state of the power to dispense justice and to make and enforce law is one of the greatest events in the whole of human history. It is the treatment of criminals after conviction that concerns us chiefly here; but as this *penology* can scarcely be understood in its development without taking into consideration the other division of the treatment of crime, called criminal procedure, we will approach it from this point of view.

The original motive in the treatment of offenders was that crude vengeance, the usefulness of which in maintaining the instinctive idea of order in primitive societies has been often studied by sociologists. The danger of free vengeance is not alone that the injured may wreak out atonement upon the innocent, but also that the infuriated avenger will limit the punishment he inflicts only by the degree of bitterness and hate he personally feels. In this way the original culprit feels that the vengeance he has felt (and his friends join him in his feeling), that the excessiveness of his suffering, now invites him to retaliate. Thus matters tend to grow worse and worse; and soon family and clan are embroiled in a permanent and destructive feud. Then a want clamors for relief. It grows into a demand and the demand finds a spokesman for reform in the person of a chieftain or other leader. For the hopeless tendency to engender feuds leads to reforms by which the chieftain seeks to suppress private revenge. Then "Vengeance is mine, I will repay" is the claim of the savage ruler. It is at this point that we find the emergence of a primitive criminal and civil procedure in all peoples that have risen out of savagery to barbarism, and the earlier stages of civilization, for it is here that the offended party goes before a judge to demand vengeance against his adversary. The purpose of this primitive court is to inflict such penalties that the injured party and bystanders will feel that justice has been done, so that these persons will be content to abstain from private revenge. Retributive justice means just such severity as group consciousness at this low stage of progress can witness with satisfaction. Next cupidity is

pitted against hate, for the influence of authority is in favor of substituting redemption for penalties that kill or maim the fighting men of the tribe; and thus is instituted the *compositio*, the *wergild* and other fines; that is where the complainant is willing and content to sell his right of vengeance.

Thus the realization of "right" is from the beginning a social function. The idea of right being incorporated in the chieftain played an important part in bringing about the acquisition by the state of power to dispense justice; and moreover the religious tendencies worked to the same end. Wickedness was held to be an injury to the deity, whose anger would be visited upon the entire land; a conception that lasted far down into the Middle Ages, and according to which the fate of Sodom and Gomorrah was held to be typical of the effect of the curse from God. Already in primitive times religion led to a strange idea of justice; secret societies consecrated by the deity (Dukduk, Egbo) took upon themselves the function of enforcing "right," instituting reigns of terror in their districts, maintaining order in society and claiming authorization from the god with whose spirit they were permeated. Later influenced by all these tendencies, the social aggregate took over the control of justice. It was already considered to be the upholder of right, the servant of the gods, the maintainer of public peace, the dispenser of sacrifices; and so the various elements conceived of as justice, which had previously been distributed among the single families, tribes, associations, societies, were at last combined and placed under state control.

Forms for the dispensation of justice judging of crimes, determining of punishments developed into judicial procedure, which for a long time bore a religious character. The Deity was called upon to decide as to "right" and "wrong." Hence those terrible judgments of God through trial by water, fire, poison, serpents, scales, combat or decision by divining eye, so closely allied to the so-called trial by hazard. The cruel mal-treatment of elderly people suspected of witchcraft in early New England is familiar to all. A peculiar variety of ordeal is that of the bier, according to which the body of a murdered man is called into requisition, the soul of the victim assisting in the discovery of the murderer. An advance in progress is the curse, which takes the place of the ordeal. Thus arise those ordeals by invocation and by oath with *compurgators*. Witnesses succeeded to conjurors; divining looks were replaced by circumstantial evidence; and instead of a magical, a rational method of obtaining testimony was adopted. This development was not attained without certain attendant abuses; and the abolition of ordeal by God was among many peoples, notably among the inhabitants of eastern Asia, some tribes of American Indians and the Europeans of the early Middle Ages, succeeded by the introduction of torture! Years ago August Comte maintained that the institution of slavery was the greatest single step up to his day in the progress of human culture, since it superseded a great amount of slaughter, with or without cannibalism. The practice of eating the criminals, which is quite a common form of cannibalism, seems to be largely due to revenge or indignation. In Lepers' Island,

in the New Hebrides, the victims of it were not generally enemies who had been killed in fighting, but it was a murderer or a particularly detested enemy who was eaten in anger and to treat him ill. In many lands torture stood in close connection with the judgment of God. That this is so is no more remarkable than the fact that religious intolerance which accompanied the rise of monotheism was the result of the nature attributed to its God. Torture in other cases originated either directly or indirectly from slavery. To obtain evidence by torture the accused person was forced through physical suffering to make disclosures concerning himself and his companions; and in case he himself was considered guilty, to a confession.

The development of Hebrew teaching on the subject will reveal the stages through which the notion of "justice" passed. First there is the injunction to moderate vengeance and *lex talionis* appears with its demand for an "eye for an eye." Second, we must leave vengeance to rulers. And lastly, "love your enemies, do good to those who despitefully use you, forgive as you hope to be forgiven."

Retaliation is finally seen to be a continuation of a moral disease; not a cure. The idea of loving one's enemies is found in the books of Saint Matthew, Saint Luke and Saint Mark; Lao-Tsze and Mang-Tsze voiced these sentiments in ancient China; we find them expressed in the Brahman Laws of Manu; Buddha taught that the hatred and revenge is not appeased by hatred (it ceases by non-hatred only); we find the same notion in Leviticus, Plato, Pliny and Epictetus, taught it to the classical world; and in the same spirit Jesus taught in His Sermon on the Mount;

"Ye have heard that it hath been said: An eye for an eye, and a tooth for a tooth: But I say unto you, That ye resist not evil." We only point out the truth of the sentiment which prompted these sayings and which should be expressed in the sentence: "resist not evil with evil." Evil must be resisted; but we must not retaliate. The rule of retaliation and the rule of forgiveness are not so radically opposed to each other as they appear to be. What the latter condemns is in reality not every kind of resentment, not impartial indignation; but personal hatred. Jesus himself certainly was not free from righteous indignation. Moreover the belief in a transcendental retributive justice, in an ultimate punishment of badness which we meet with in Taoism, Brahmanism, Buddhism and Christianity, side by side with the doctrine of forgiveness is founded on the demand that wrong should be resented. What is taught by all the great teachers who have been mentioned is good will to the good and to the bad alike. This is based on the consideration that all creatures, both good and bad alike, are ultimately products of circumstances; and, therefore, that the bad deserve compassion, not hatred. A novelist (George Eliot) has told us that it was the "illusion" of one of her characters that he trusted "in his own skill to shape the success of his own morrows, ignorant of what many yesterdays had determined for him beforehand." The modern Italian school of criminology strikes this note again and again; it is a diapason whose slow and solemn vibrations, communicated to their

own meditations, all readers of the literature of the new criminological determinism of Italy, will recall.

The laws of ancient Rome still command respect and in cases obedience in many civilized communities. We note the following punishments meted out to the offender in ancient Rome: There was the *multa*, or fine; *vincula*, imprisonment or fetters; *verbera*, or stripes; *talis*, or infliction of punishment similar to injury, limb for limb; *infamia*, public disgrace, by which the delinquent, besides being scandalized, was rendered incapable of holding public office and deprived of other privileges of Roman citizenship; *exilium*, banishment (*aquae et ignis interdictio* accomplished this); *servitus*, or slavery; *mors*, death either civil or natural (banishment and slavery are civil death). Natural death was brought about by beheading, scourging, strangling or throwing the criminal headlong from the Tarpeian rock, or from the place in a prison, from the Robur. Many have been the changes. Capital punishment has ceased to be a retaliation and has become more and more a mere protection against the repetition of a crime. As it would be wrong to leave a tiger abroad so a man who by his very nature is a murderer should not be allowed to remain at liberty. Since imprisonment is on the one hand not a sufficient guarantee for the safety of society and on the other hand is perhaps a more cruel treatment than death, capital punishment remains, under our present civilization, still a necessity of our penal code. Yet in all this the attempt is no longer made, to retaliate on the murderer the cruelties which he has committed; it is a maxim that the death punishment should be inflicted with as little pain as possible. The infliction of pain is not an act which men now regard with indifference, even in the case of the criminal, and to many enlightened minds it has appeared both unreasonable and unjust and cruel that the state should wilfully torment a criminal to no purpose. But while retributive punishment has been condemned, punishment in a new sense has been defended and looked upon in a different light, not as an end in itself, but as a means. It is to be inflicted not because wrong has been done but in order that wrong may not be done. Its object is held to be either to deter from crime or to reform the criminal and by means of elimination or seclusion to make it impossible for a criminal to commit fresh crimes. In the case of capital punishment the criminal is simply no longer allowed to live and it has ceased to be a revenge or retaliation. It has become a cure founded on the experience that a man who committed one murder is likely to commit a second murder. Hence a man who has killed another not on account of his innate or inbred murderous inclination, but through the unhappy complication of circumstances (under an unwritten law), will not be treated as an habitual murderer; and according to the laws of all civilized countries is not punishable by death.

Behind bars no criminal ought to be pampered, but should receive prison fare and prison treatment in accord with the regulation of the place where his deeds have brought him. For all this is curative. An execution for murder is merely the removal of a dangerous member from society and this for the same reason that a limb of the body infected by in-

curable disease must be amputated. Some recent tendencies by some well-meaning people are so naïve that one is tempted to call them childish; the conventions of society cannot be abandoned to alleviate the sufferings of criminals. To do so would be to act about as logically as it would be to abandon all medicine that leaves a bad taste in a patient's mouth. At the same time most lawyers might well remember that life is preferable to rules of health and that not a few of our laws are capable of becoming outgrown. Our penal laws are not as yet fully adapted to the new view. All our minor punishments are still retaliatory, which fact makes our prisons all too frequently breeding places of crime and vice, instead of what they ought to be, namely, moral hospitals. Perhaps a just test of any penal system is to be found in the quality of discharged convicts, and according to Mr. Eugene Smith, president of the Prison Association of New York it is a notorious fact that the most desperate class of criminals consists of discharged convicts.

PUNJAB, pŭn-jăb', or **PANJAB** (Persian, "Five Waters"), an extensive territory in the northwest of Hindustan, formerly under the dominion of the Sikhs, but in 1849 annexed to British India. It is so called from its position, being intersected by the five great rivers which unite to pour their waters into the Indus. In 1901 the northwestern part of the Punjab was separated to form a chief commissionership under the government of India (see NORTH-WEST FRONTIER PROVINCE). The lieutenant-governorship as thus limited is bounded on the east by Kashmir, Tibet, and the river Jamna; on the south by Sind and Rajputana, the river Sutlej being in part a boundary river; on the west by Baluchistan and Northwest Frontier Province; on the north by the Northwest Frontier Province. For administrative purposes it is divided into divisions (Jalandhar, Lahore and Rawal Pindie). Lahore is the capital, while Amritsar, the sacred city of the Sikhs, is the next largest city, since Delhi has been detached. Simla, the mountain capital, is within the province, and is the residence of the viceroy during the hot season. Murree is the summer headquarters of the military command. The total area of the province is about 95,000 square miles, with a population of about 19,974,956. The area of the Native States is 38,299, with a population of about 4,250,000.

General Description.—The province of the Punjab is a triangular tract of land between the Sutlej and the Indus, and, with the exception of the hill country on the slopes of the Himalayas, it is a great alluvial plain. On the northeast side is the margin of the Himalayas, on which there are beautiful sanitarium, or hill stations—Simla (the mountain capital of India), Dagshai, Sabathu, Kassauli, Dharmasala, Dalhousie and Murree, the military headquarters of the province. The country between Jhelam and the Indus is known as the salt range, as it contains inexhaustible mines of rock salt which have been worked for many centuries. It is abundantly irrigated by six rivers. These rivers (proceeding from west to east) are the Indus, the Jhelam (ancient *Hydaspes*), Chenab (ancient *Acesines*), the Ravi (ancient *Hydraotes*), the Beas (ancient *Hyphasis*) and the Sutlej (ancient *Hesudrus*).

The Jhelam and Chenab unite their waters, and then are joined by the Ravi; the united stream is then augmented by the Sutlej, which has previously received the Beas. The combined waters of these rivers form the Panjnad, which joins the Indus near Mithankot. The rivers of the Punjab divide it into five districts, or *doabs* (countries between two rivers): namely, the Sind-Sagar Doab, between the Indus and Jhelam; the Jech Doab, between the Jhelam and Chenab; the Rechna Doab, between the Chenab and Ravi; the Bari or Manja Doab, between the Ravi and Beas; and the Jallandar Doab, between the Beas and Sutlej. Of these the first is by far the largest, but also the most sterile and least inhabited, abounding with bare eminences and rugged declivities, interspersed here and there with rich and fertile valleys. The second is mostly level, and has been described as "a sterile waste of under-wood," the abode of shepherds, and scantily irrigated; the Rechna Doab is bare and neglected, though susceptible of high cultivation; the Bari Doab, though bare, has a large surface under cultivation, and is the most populous and important of all, containing the large towns of Amritsar, Multan and Lahore; while the Jallandar Doab is highly cultivated, well peopled and excelled in climate and productions by no province in India. Speaking generally, the plains east of Lahore are the most fertile, wealthy and populous of the province, and the granary of the Punjab; while those on the west present a striking contrast. The soil of the level country varies remarkably from stiff clay and loam to sand, mixed with each other in variable proportions, and with vegetable matter; besides which, carbonate and sulphate of soda are sometimes mixed with it in such quantities as to render the land almost worthless. The mineral wealth of the Punjab is almost confined to its rich deposits of rock salt. The climate is hot and dry, and little rain falls, except in the higher country and under the influence of the southwest monsoon. The part of the province to the east of Lahore can be cultivated in most seasons without irrigation, but owing to this its crops are much more likely to fail from a deficiency of rainfall than those of the western irrigated tracts. The summer heat is very great, and in the early part of January sharp frosts are common.

Vegetation, Agriculture.—Wood is scarce, except upon the hills. In the west considerable areas are occupied by date-trees; and palms of other species, banyans and other trees are found here and there. The area under forests is over 4,250,000 acres. About 28,000,000 acres of the remainder are under cultivation, and over 20,000,000 acres more are available for cultivation. The principal grain crops are wheat, barley, rice, buckwheat and millet, pease, vetches and mustard; sesamum and other oil seeds, turnips, carrots, onions, cucumbers and melons. Indigo and sugar are exported. The tobacco plant grows luxuriantly, especially about Multan, and opium has been grown somewhat extensively. About 8,750,000 acres are under wheat, and over 750,000 under rice. The total irrigated area exceeds 9,000,000 acres, of which more than half is irrigated by canals. Among the fruits are the date, orange, fig, vine, apple, mulberry, banana and mango.

The livestock includes sheep, cattle, horses and camels; buffaloes are common.

People.—The population of the Punjab is composed of various races, the chief of which are the Jats, Rajputs and Pathans. The Jats form the bulk of the agricultural peasantry, and are tall and athletic, with handsome, open countenances, long beards and fine teeth. The people, generally, are in physical respects superior to those of Bengal. The native states subordinate to the Punjab government are 36 in number. Thirty-one are Hindu and five Mohammedan. The most important is Kashmir, the next Patiala. The Mohammedan state of Bahawalpur is the next followed in order by Kapurthala, Mandi, Sarmur, Faridkot and Malarkotla. The other states are insignificant in rank and consequence.

Religion.—The religion of the Sikhs, which is the national religion of the Punjab, was founded by Nanak, who was born A. D. 1469. The Golden Temple at Amritsar is the centre of the faith and the guardian of the sacred book known as the *Adi Granth* (see *SIKHS*). The distribution of the population according to religious profession is almost wholly Mohammedan and Hindu, there being some Sikhs, and a sprinkling of other religions. The American Presbyterian Board of Missions has important stations at Lahore, Ludianah and Umballa. Lahore is the seat of both a Church of England bishop and a Roman Catholic bishop. The Mohammedans form a very large part of the population of the Rawal Pindee and Multan divisions. The Hindus predominate in the easterly divisions and in the mountainous district of Kangra. The Sikhs reside chiefly in the centre and east of the province and constitute the mass of the gentry. The few Buddhists of the Punjab are almost entirely confined to the small Spiti district in the extreme northeast. The Pathans and Baluchis are the most numerous of the Punjab Mohammedans by race, but the Mohammedan strength consists largely in converted Hindus belonging to the Jat and Rajput tribes. The Hindu Jats form a large proportion of the population.

Language and Education.—The chief languages spoken in the Punjab are Punjabi (known as *Gurmukhi*), Hindi, Sindhi, Jataki, Kashmiri, Pushtu, Persian and English. Since the country came under British rule elementary education has received much attention. The total number of educational institutions in the Punjab is about 8,000, with a total of over a quarter of a million scholars. Of the higher educational institutions of the province the following may be mentioned:—the Punjab University at Lahore; Lahore Government College; Oriental College; Saint Stephen's College, Delhi; Lahore Medical School; Saint Thomas College, Murree; the Khalsa College, Amritsar; Bishop Cotton School, Simla; and the Lawrence Military Asylum, Sanawar.

Manufactures and Trade.—The manufacturing industry of the Punjab is chiefly confined to the larger towns. Amritsar, Lahore, Multan and Shujabad are distinguished for their silk and cotton fabrics, and the silks of Multan called *kair*, and chiefly used for scarfs, possess a strength of texture and brilliancy of color for which they are much prized in the Indian markets. The shawls of Lahore, too, rank only second to those of Kashmir. Bro-

cades, tissues and carpets, resembling the Persian, are also manufactured in the capital. In the east of the Punjab white cotton goods are prepared of a stronger and more durable texture, as well as cheaper, than those of British manufacture. The Punjab enjoys from its position an extensive transit-trade. The imports comprise sugar, spices and other groceries, dye-stuffs and cottons, woolen and silk fabrics, metals and metallic utensils, cutlery, precious stones, ivory, glass and cochineal, asafoetida, safflower, fresh and dried fruits, wool, horses, etc. The exports—partly of home produce, partly in transit—comprise grain, *ghee*, hides, wool, silk and cotton fabrics, carpets and shawls, raw silk and cotton, indigo, tobacco, hardware, horses, etc.

Government and Revenue.—The province is under a lieutenant-governor, assisted since 1897 by a legislative council of nine members. The most important item of revenue is the land-tax, which, on the average, yields a net revenue, after deducting charges, of nearly £2,000,000; besides there are excise duties on spirits and drugs, duties on stamps, etc. The financial condition is so favorable that there is often a clear surplus of revenue over expenditure of £2,500,000. About one-half of the whole cultivated area of the Punjab is tilled by owners, and about 1 per cent by tenants paying a nominal or no rent. Of the remaining area one-fifth is cultivated by occupancy tenants, and the rest is held by tenants-at-will, a class increasing in numbers from year to year. Rents vary from five annas to 40 rupees per acre, the average being about two and two-thirds rupees. On about two-thirds of the land held by tenants-at-will the rent is wholly or partly paid in kind, and the average rent payable in kind is for the whole province about two-fifths of the produce. Nearly 5,000,000 acres are under mortgage.

Army and Police.—The Punjab forms a military district called "The Northern Command," under a lieutenant-general with headquarters at Rawal Pindee. The military authority of this officer extends to the Northwest Frontier Province. The military cantonments are Rawal Pindee, Peshawar, Noroshera, Abbottabad, Sialkor, Jhelum, Lahore, Jullundur, Sirhind, Umballa, Ferozepore, Kohat, Bannu and Murdan under a lieutenant-general. The military force stationed in the Punjab in 1900 consisted altogether of 68,806 men. Of cavalry there were 11,893, of infantry 50,504, of artillery 6,120, with some engineers, etc. There were thus more troops in the Punjab than in any other division of India. The police force is stated to be in a most effective condition. It numbers about 20,000 men, divided into two divisions, the Trans-Sutlej and the Cis-Sutlej. Almost all the police are armed either with swords or guns. The Punjab has a chief court with five judges, two of whom are natives—and four temporary judges.

History.—The Punjab plays an important part in the history of Hindustan and British India. It was invaded in 327 B.C. by Alexander the Great, who defeated Porus at Mong in Gujarat and overran the whole country. In 1022 it was overrun by the troops of Mahmud of Ghazni, whose successors held the country for 170 years, making Lahore the seat of their government. In 1193 it passed by conquest into

the hands of Mohammed Ghorī, and Delhi became the capital. After his death the country was ruled by a succession of turbulent chiefs, principally Afghans, till at length in 1526 Baber, the founder of the Mogul Empire, having obtained possession of the country, ascended the throne, and established a dynasty whose sway prevailed for about two centuries, during which the Sikhs were rising into importance. In 1738 Nadir Shah overran the Punjab, and in the following year he defeated the Mogul army at Karnal and sacked Delhi. The Sikhs were utterly defeated by the Afghan conqueror Ahmed Shah Durani in 1762, and the Moguls nominally ceded the Punjab to him. The Durani dynasty maintained its ascendancy till the beginning of the 19th century, when the Sikhs under Ranjit Singh began their career of conquest. In 1818 this renowned chieftain stormed Multan and took Peshawar—in the following year conquering Kashmir and Derajat west of the Indus; and in 10 years he succeeded in establishing his power over the whole country. In 1839 Ranjit Singh died. His son Khorak Singh quietly succeeded, but died of a decline a few months after his father, on which Sher Singh, a natural son of the great Ranjit, assumed the sovereignty, but was assassinated 15 Sept. 1843. Dhulip Singh, the reputed son of Ranjit Singh, succeeded his brother. This young prince was converted to Christianity and retired on a princely pension to England, where he died. But from the close of 1843 to the period of its annexation to British India the government was in abeyance, or, what is worse, in the hands of an ignorant, bloodthirsty, rapacious and insubordinate army. At length it became manifest that the Sikhs of the Punjab were preparing for an irruption into the territories protected by the British on the east of the Sutlej. In the end of December 1845, the Sikh forces passed the Sutlej into the territories protected by the British, with a most formidable train of artillery, but they found themselves completely worsted after the hard-fought actions of Mudki, Ferozeshah, Aliwal and Sohraon. Lahore and other stations were afterward occupied by British troops: the Jallandar Doab, between the Sutlej and Beas, was permanently ceded to the British; and the province of Kashmir and the other provinces of the Himalayas were vested in the Rajah Gholab Singh. In 1849 a conspiracy between several disaffected chiefs and the Afghans resulted in further hostilities against the British, Multan being the centre of their operations. The indecisive battle of Chillianwalla was followed by the capture of Multan in January, and the victory of Gujrat in February 1849, since which period the former territories of the Sikhs have formed an integral part of the British Empire. The most important subsequent event in the history of the province was the Indian Mutiny, when the Sikhs were loyal to the British government, and the present Sikh regiments of the British native army form the most important section of the military strength of the empire, the Sikhs and the Gurkhas being esteemed by many critics the finest soldiers in the world. After the suppression of the mutiny the province was erected into a lieutenant-governorship under Sir John Lawrence, the distinguished statesman.

chæological Survey of India,' Vol. XIV (London 1882); Gore, 'Lights and Shades of Hill Life in the Afghan and Hindu Highlands of the Punjab' (London 1895); Latif, 'History of the Punjab from the Earliest Antiquity to the Present Time' (London 1896); Medlicott, 'Sketch of the Geology of the Punjab' (Calcutta 1888); Prinsep, 'History of the Punjab'; Griffin, 'The Rajas of the Punjab' (2d ed., London 1872); Honigberger, 'Thirty-five Years in the East'; Edwards, 'A Year on the Punjab Frontier'; Clark, 'Thirty Years of Missionary Work in the Punjab'; 'Punjab Gazetteer' (Calcutta).

PUNJABI LANGUAGE AND LITERATURE.

Punjabi (also Panjabi from Persian *Punjabī*—"Five Rivers") is an ancient Indian or Hindi dialect. Of a total population of about 26,000,000 inhabiting the Punjab (or Panjab) a large district in northwest India, some 18,000,000 to 19,000,000 speak Punjabi as their common vernacular; some 4,000,000 use Hindustani, the remainder speak the hill dialects; the Pahari or Hindustani is, however, employed in the law courts and officially in all intercourse with the natives. Punjabi has been enforced by many words borrowed from Persian and Arabic, and is, therefore, an Aryan language belonging to the central group. But the number of original Sanskrit words in its vocabulary (called *tatsama*) is small, especially when compared with Bengali and Uriya (two eastern forms of Hindi). Punjabi again has a number of dialects, fusing into one another, as is invariably the case with dialects throughout India. The main ones of these are Multani (in the south) which partakes both of Punjabi and Sindhi; next, Jathki (in the Centre) and Chibhali-Dogeri (in the north). There are also several alphabets in use, the most ancient of which is Gurmukhi, derived from the Dervanagari alphabet, a Sanskrit form, though somewhat altered, omitting also a number of signs. The Gurmukhi is likewise in vogue among the Sikhs. Then there is the Lundi alphabet, used for commercial purposes. However, the British government adopted the Arabic character, as being the most convenient for the purpose. There is really no literature in Punjabi, with the single exception of the Sikh Granths. Parts of the Bible, though, have been translated into Multani and Chibhali-Dogeri. The Sikh Granths in Punjabi, or Adi Granth, are a compilation of the laws and precepts of the Khalsa, a peculiar sect whose holy city was Amritsar, founded by Mānak. The Khalsa (lit., the Pure) aimed in their teaching partly for political, partly for religious reasons, at the brotherly amalgamation of Hindus and Moslems in the Punjab. For several centuries the Khalsa played a conspicuous rôle in that portion of India. This was more especially the case during the 17th century. Under British influence, however, the Khalsa gradually ceased to promulgate their doctrine. The Granths spoken of, show the Punjabi vernacular at its best. Consult Bhai Maya Singh, 'Punjabi Dictionary' (Lahore 1895); Bailey, Wm., 'Punjabi Grammar' (ib. 1904); Grierson, Sir G. E., 'Linguistic Survey of India: Western Hindi and Punjabi' (Vol. IX, part I, Calcutta 1908).

WOLF VON SCHIEBRAND,

Author of 'America, Asia and the Pacific.'

PUNJNUD, or **PANJNAD** ("the five rivers"), a stream of the Punjab, formed by the Sutlej, Beas, Ravi, Chenab and Jhelam, whose waters it carries to the Indus (q.v.), about 490 miles from the sea near Mithankot. The Punjnud bounds Punjab and Bahawalpur in part of its course.

PUNKAH, a large swinging fan used in India and other hot countries for ventilating rooms. It consists of a movable frame of wood covered with canvas or the like and suspended from the ceiling. It is pulled backward and forward by means of a cord, and thus causes a movement of the air in the apartment.

PUNO, poo'nō, Peru, (1) town, capital of the department of Puno, on the west shore of Lake Titicaca, 12,870 feet above sea-level, and 90 miles east by south of Arequipa. It has two churches, a college and a hospital. A railway runs to Arequipa and to Mollendo on the Pacific. Pop. 6,000. (2) The department of Puno; area, about 41,198 square miles, is mountainous. The principal crops are potatoes and barley, but it is particularly distinguished by the extent of its pastures, cattle raising being the chief occupation. Its principal exports are the wool of the sheep, llama, alpaca and vicuña, and some cascarilla bark from the valley of Carabaya. Pop. about 540,000.

PUNSHON, William Morley, English Wesleyan Methodist clergyman: b. Doncaster, Yorkshire, 29 May 1824; d. London, 14 April 1881. He studied at the Wesleyan College, Richmond, and in 1845 was received into the ranks of the ministry, his ordination occurring in 1849. He held charges in Newcastle-on-Tyne, Sheffield, Leeds, London and Bristol and became famous as a preacher. In 1868 he went to Canada where he worked assiduously to strengthen the position of the Methodist Church and he became widely known as a preacher and lecturer in both Canada and the United States. He was five times president of the Canadian Conference, and in 1873 he returned to England. He was elected president of the Conference in 1874 and in 1875 became one of the general secretaries of the Wesleyan Methodist Missionary Society. Author of 'Sabbath Chimes,' verse (1867); 'Sermons and Lectures' (3 vols., 1882-84). Consult Macdonald, F. W., 'Life of William Morley Punshon' (1887).

PUNT, poont, an ancient country on the Red Sea, whether in Asia or Africa is disputed. The country is mentioned a number of times in the Egyptian hieroglyphics, and such records show that the Egyptians obtained from Punt ostrich feathers, leopard skins, gold, incense, ivory, precious woods and various ornaments. There are good reasons for locating Punt where is now Somali Coast and Abyssinia. Accounts are given of journeys to Punt, undertaken by command of monarchs. Queen Hatshepsut sent thither a whole fleet, and the account of the voyage, the persons and places seen in Punt were recorded on the walls of the temple of Deir el-Bahri. Consult Müller, 'Asien und Europa'; Naville, 'Deir el-Bahri'; Erman, 'Life in Ancient Egypt.'

PUNT, an oblong flat-bottomed boat used for fishing and shooting in shallow waters. The most common mode of propulsion is by pushing with a pole against the bottom of the river, or

stream, a process which is hence called punting. Also a similar boat used for racing on the Thames, England.

PUNTA ARENAS, poon'ta a-rā'nās (Sandy Point), Chile, port and capital city of the territory of Magellanes, at the extreme end of Patagonia (lat. 53° 10' S.), and lying in a plain bounded by the rivers Las Minas on the north and La Mano on the south, with wooded hills back of the river. The city is a coaling station for steamers passing through the Strait of Magellan, and as such has of late years risen to considerable importance. The surrounding country produces rye, barley, potatoes and other similar crops and the timber exported to the Falkland Islands. The seal fisheries are considerable. The city has banks, stores, hotels and an opera-house. The site was made a penal colony in 1843 and the town was founded in 1849. Pop. about 20,000.

PUNXSUTAWNEY, Pa., city in Jefferson County, situated on Mahoning Creek and on the Pennsylvania and North Western, the Buffalo, Rochester and Pittsburgh and the Buffalo and Susquehanna railroads, about 90 miles northeast of Pittsburgh. It is the business centre of a great bituminous coal and coke region and the headquarters of the second largest producers of bituminous coal and coke in the United States. There are also large iron furnaces and numerous smaller industries. It is also the centre of a rich agricultural territory. Punxsutawney affords exceptional advantage for manufacturers of iron and steel products, as the pig iron is manufactured here and the coke to smelt it is also produced here, a combination that makes for the lowest possible cost of production. The cheap natural gas available here has attracted large glass manufacturing plants, which are very successful. The prosperity of the city is reflected in the rapid growth of the three large banks serving the business interests of the community. Punxsutawney is an Indian name. It was organized into a borough in 1850. Its growth since 1890, when it had a population of 2,792, has been rapid. Its Chamber of Commerce is well organized and there is an active Business Men's Association. Greater Punxsutawney now has a population of 12,000.

PUPA, the name applied to the second stage in the metamorphosis of insects. In the typical complete or holometabolic insects, exemplified by beetles, the *Lepidoptera*, flies, etc., the pupa stage is marked by quiescence and rest, and thus presents a contrast to the preceding and active larval stage. During the pupa stage the elements of the larval form are being remodeled into that of the *imago* or perfect insect, which in due time emerges from the pupa case. An insect may remain in the pupa stage from a few hours or days to weeks, months or even years.

The pupæ of the hemimetabolic insects, or those which undergo an incomplete metamorphosis (such as grasshoppers, locusts, bugs, etc.), are called nymphs and differ from the perfect insect, which they resemble in form, chiefly in the absence or rudimentary nature of the wings. These latter structures in the pupa state of hemimetabolic insects may generally be perceived to be in course of formation, the perfect insect or imago state being characterized simply by the full development of the wings. See CHRYSLIS; INSECTS; METAMORPHOSIS.

PUPIN, Michael Idvorsky, American scientist and inventor: b. Idvor, Hungary, 4 Oct. 1858. He came to America in 1874, was graduated at Columbia in 1883 and as the first American holder of the John Tyndall Fellowship of Columbia studied physics and mathematics at Cambridge University and under the famous von Helmholtz at the University of Berlin, there taking his degree of Ph.D. He returned to teach at Columbia, was appointed adjunct professor of mechanics there in 1892 and has been professor of electro-mechanics there since 1901. He is the inventor of long-distance telephony by means of self-inducting coils placed at intervals about the wire which preserving the vibrations and resonance transmits the sound a greater distance. Professor Pupin first announced the theory underlying his invention in March 1899, and brought his system to such perfection that in 1901 it was acquired by the Bell Telephone Company and by German telephone interests. He has perfected other valuable inventions in electrical-wave propagation, electrical resonance, in iron magnetization and in multiplex telegraphy. He was appointed director of the Phoenix Research Laboratories in 1911. In 1917 he presented to the United States government the use of his invention for eliminating static interference with wireless transmission. Appointed honorary consul-general in New York for Serbia, he was an active agent for that country during the World War, and organized for relief work a corps of Columbia students who served in Serbia in 1915. He has published 'Thermodynamics of Reversible Cycles in Gases,' etc.

PUPPET-SHOWS, an amusement or entertainment popular in Europe. One of the most common classes of puppets is called, in French, *marionnettes*. These are images of the human figure moved by wires or cords on a stage and made to perform little dramas, the dialogue of which is carried on by the person in concealment, who moves the figures. In the common street performance in England of Punch and Judy (q.v.), however, the performer puts his fingers in the figures. Puppet-shows were common among the Greeks, from whom the Romans received them. Xenophon, Aristotle, Gellius, Horace and others mention them. Such exhibitions, which are so pleasing to children and the uneducated, naturally passed through various degrees of perfection in different ages and even now exhibitions of puppets are common in some countries which display great mechanical ingenuity. Clocks often display movable puppets and it is not infrequent in Germany to find on ancient town-clocks puppets which move whenever the clock strikes. In 1674 there was a puppet opera at Paris, which met with great applause. They have been popular in many European cities, especially in Italy.

PURACÉ, poor-rä-sä', a volcano of the Andes in Colombia, 20 miles east of the town of Popyan. Eruptions have occurred several times; the town of Puracé at the base of the mountain was destroyed by the eruption of 1827; and the top of the volcano blown off and its height reduced to 15,420 feet by the eruption of 1849. It is still active and hot vapors issue constantly from the crater.

PURANAS, poo-ra'nas. See SANSKRIT LANGUAGE AND LITERATURE.

PURBECK (për'bèk) BEDS, a series of geologic beds or strata consisting of limestones, clays, shales and sandstones, which in England form the uppermost member of the Jurassic system (q.v.). They are named after the Isle of Purbeck on the southeast coast of Dorsetshire, where they are exceptionally well developed and yield among other building stones a limestone, susceptible of a good polish, which is known as Purbeck marble. The 'Isle' is in fact a peninsula 12 miles long by 7 miles broad, almost completely surrounded by sea. The Purbeck beds appear in a chalky ridge which traverses the island from west to east.

PURBECK, Isle of. See PURBECK BEDS.

PURCELL, pèr'sèl, Henry, English composer: b. London, 1658; d. 21 Nov. 1695. He was the son of a musician of the chapel-royal, who left him an orphan in his sixth year. He was admitted a chorister in the king's chapel, where he studied music under Choir-master Cook and his successor, Pelham Humphrey, and afterward under Dr. Blow. In 1676, when only 18, he was made organist of Westminster Abbey and six years afterward was appointed to fill the same office at the chapel-royal, Saint James. From this period his fame increased rapidly, his anthems and other church music being popular in all the cathedrals of the kingdom; nor were his compositions for the stage and music-room less successful. He composed music, religious and secular, with equal facility; and with respect to chamber music his compositions superseded all prior productions. Of his numerous works his 'Te Deum' and 'Jubilate' were composed for the celebration of Saint Cecilia's Day, 1694. Of his instrumental music a collection was published two years after his decease and comprised pieces in four parts, for two violins, tenor and bass. Many of his songs were published after his death under the title of Orpheus Britannicus. 'Ye Twice-Ten Hundred Deities,' contained in this collection, is considered the finest piece of recitative in the language; while his music in 'King Arthur' has maintained its popularity undiminished to our own day. In 1695, the year of his death, he set to music 'Bonduca,' an opera altered by Dryden from Beaumont and Fletcher; but his chief opera is 'Dido and Æneas' (1689). He was the author of a vast variety of catches, rounds, glees, etc., remarkable both for their melody and for their spirit, humor and originality. He was buried in Westminster Abbey. A splendid edition of his works is published by the Purcell Society, founded in 1878. An earlier edition of his sacred compositions is that of Novello (1829-32). Consult Cummings, 'Life of Henry Purcell' (1882).

PURCELL, John Baptist, American Roman Catholic archbishop: b. Mallow, County Cork, Ireland, 26 Feb. 1800; d. Brown County, Ohio, 4 July 1883. He came to the United States in 1818, was educated at Mount Saint Mary's College, Emmitsburg, Md., received minor orders, and later studied at Saint Sulpician's College in Paris. He was ordained in 1826 and in 1827 appointed to the chair of philosophy in Saint Mary's College, of which he became president in 1828. In 1833 he was consecrated bishop of Cincinnati, and at once set about the im-

provement of the diocese under his charge, and in 1846 the number of churches under his control had increased from 12 to 70, the number of Roman Catholics from 6,000 to 70,000. He founded schools and academies, built a convent for the Ursulines, and in 1847 the diocese of Cleveland was formed out of that of Cincinnati at his request and placed in charge of another prelate. In 1850 he was made an archbishop and in 1851 received the pallium from the Pope's own hands. He founded Mount Saint Mary's of the West, destined to become one of the leading theological seminaries of the country, and in 1855 presided over his first provincial council. New sees were formed from his diocese in 1868, but though their creation had limited his diocese in extent, it still contained 140,000 Roman Catholics. He attended the Vatican Council in 1869 and celebrated his golden jubilee with great rejoicing among his people in 1876. In 1879, however, his hitherto unbroken prosperity was interrupted. His brother Edward had been appointed his vicar-general and the financial affairs of the diocese had been left by the bishop entirely in his brother's care, trusting implicitly in the latter's financial ability, which was unfortunately as little as the bishop's own. When the crash, rendered inevitable by faulty business methods, came, Edward died broken-hearted. The indebtedness reached nearly \$4,000,000, and the crisis came at a time of general financial panic. The bishop, however, was never accused of any dishonesty, though the unwisdom of his confidence in his brother was widely criticised. His own light regard for the value of money was well known, as he had served as bishop for 25 years before he accepted even the "cathedraticum" of \$5,000 a year, and when paid it usually was given away before night. He tendered his resignation in 1880, but it was not accepted though he was given a coadjutor. At his death the Roman Catholics in his original diocese numbered half a million. He published a series of textbooks for the use of Roman Catholic schools in his diocese.

PURCELL, Okla., city and county-seat of McClain County, on the Canadian River, 35 miles, direct, southeast of Oklahoma City, on the Atchison, Topeka and Santa Fé and the Gulf, Colorado and Santa Fé railroads. It is located in a cotton district which produces also alfalfa and grain. There are cottonseed-oil and flour mills, and grain elevators. Pop. 2,740.

PURCHAS, *pér'chas*, Samuel, English author and Anglican clergyman: b. Thaxted, Essex, about 1575; d. London, September 1626. He was graduated from Cambridge, took holy orders, was vicar of Eastwood, Essex, 1604-13, and in 1614 became rector of Saint Martin's, Ludgate, London, where he remained until his death. He published in 1613 'Purchas his Pilgrimage, or Relations of the World and the Religions Observed in All Ages and Places,' supplemented in 1625 by 'Purchas his Pilgrimages' in four volumes. The first is his own work and the latter a collection of the narratives of different travelers, edited by him. The latter was illustrated with maps, and the edition of 1626 was supplemented by a fifth volume. It was a work of great value in its day, giving accounts of travels in Europe, Asia, Africa and America, and was soon imitated. It

is valuable to-day as revealing the ideas prevailing in England at that time concerning the rest of the world at large. He also wrote 'Microcosmos, or the History of Man' (1619); 'The King's Tower and Triumphal Arch of London' (1623).

PURCHAS JUDGMENT, an English ecclesiastical decision rendered against Rev. John Purchas by the Privy Council of Appeals, 16 May 1871, in a case carried to it from the Canterbury Court of Arches, where an adverse decision was rendered 3 Feb. 1870. Purchas was charged with introducing and sanctioning Popish practices at Saint James' Chapel, Brighton, where he was perpetual curate; the objectionable practices, including the use of the cope, chasuble, alb, biretta, crucifixes, images, holy water, incense and the introduction of processions. The charges were brought against Purchas in the Canterbury Court of Arches by Colonel Elphinstone, and a decision against Purchas was given on eight points, the defendant to pay the costs of the action. Purchas made no appearance at the trial, affirming illness and lack of funds to pay for counsel. The promoter of the suit was not satisfied with this decision and appealed to the Queen in Council, but died before the case was tried. It was then taken up by Henry Herbert, of Brighton, and a decision against Purchas was rendered on practically all the points raised. Purchas had meantime placed all his property in his wife's hands, so that the costs could not be collected from him; and he was said to continue the illegal practices. He was suspended from the discharge of his clerical office 7 Feb. 1872, but he disregarded the order and continued his services as usual until his death at Brighton, 18 Oct. 1872.

PURCHASE SYSTEM, a system of appointment and promotion for officers, prevailing in the English army from the time of Queen Anne until 1871, when it was abolished by royal warrant. About half of the officers of the army received their appointments under it. It was possible to purchase an ensigncy or cornetcy for £450, a price fixed by government regulation, and subsequent promotion could be purchased, as vacancies occurred, up to the rank of lieutenant-colonel. The prices fixed by regulations were as follows:

Lieutenant-colonel	£4,500
Major	3,200
Captain	1,800
Lieutenant	700
Cornet or Ensign	450

Vacancies in certain popular regiments, particularly the Guards, commanded fancy prices, but no position could be purchased unless the officer holding it chose to sell. No rank above lieutenant-colonel could be purchased. Death vacancies, vacancies occurring through augmenting a regiment and those resulting from the promotion of colonels to be major-generals were filled without purchase either by seniority or special merit. The purchase system did not exist in the artillery, engineers, marines, 19th to 21st regiments of cavalry and 101st to 109th regiments of foot.

In the United States army and navy discharge by purchase may be secured in peace times by enlisted men in the second year or

first six months of the third year of enlistment upon presentation and verification of satisfactory reasons. The price of purchase in the first month of the second year is \$120, and is \$5 less each succeeding month during the period in which discharge may be secured by purchase. The favor will not be granted a second time.

PURDUE UNIVERSITY, the Indiana State College of Agriculture and Mechanic Arts, is located at Lafayette, Ind. It was established under the land grant act of Congress in 1862 and in 1869 was named for John Purdue, who gave \$150,000 and 100 acres of land to the State for the institution. It was first opened to students in 1874. Its present organization includes seven schools: (1) the School of Mechanical Engineering; (2) the School of Civil Engineering; (3) the School of Electrical Engineering; (4) the School of Chemical Engineering; (5) School of Agriculture; (6) the School of Science; (7) the School of Pharmacy. All of these offer regular courses extending over four years and leading to the bachelor's degree. The School of Pharmacy also offers a two years' course and the School of Agriculture a special short winter course. The degree of bachelor of science is conferred in all departments. Graduate work is provided for leading to the degrees of master of science, master of science in agriculture, mechanical engineer, civil engineer, electrical engineer and chemical engineer. Under the Federal law establishing the institution, instruction in military science and tactics is required of all male students during the first two years. The institution is coeducational, women enrolling in the schools of science, pharmacy and agriculture. The institution owns about 1,000 acres of land, of which 600 are adjacent to its buildings and used for campus and experimental farm purposes. There are 24 principal buildings, including a library, erected in 1913, and the university auditorium, a gift of Eliza Fowler. An important feature of the institution is its series of laboratories, all well equipped with modern scientific appliances. The engineering plant is particularly complete, including a locomotive testing plant, the first of its kind to be installed. The library contains about 60,000 volumes and pamphlets, mostly of scientific and technical character. Tuition is free for residents of the State. The income of the university is derived from the land grant fund of 1862, from subsequent Federal appropriations, from the State mileage tax, from student fees, etc. The total income of the institution for all purposes for the year ending 30 June 1916 was \$972,233. Its property, buildings and equipment has an estimated value of \$2,400,000. The number of students enrolled for the year ending June 1916 was 2,398, of which over 1,900 were in college classes in courses leading to degrees. Co-ordinated with the departments of instruction are the Agricultural Experiment Station and the Department of Agricultural Extension, maintained by Federal and State appropriations, the former concerned with agricultural research and the latter with the diffusion of knowledge on agricultural subjects to the people of the State. The university ranks high among schools of technology and holds an influential place in the educational system of the State.

PURE FOOD ACTS. Pure food legislation has been rendered necessary by the willingness of producers to flood the markets with food products, drinks and drugs which are adulterated. These adulterations were induced by the desire of manufacturers to increase their profits. The practice resulted in wholesale frauds upon the public which unwittingly bought inferior articles labeled as goods of standard quality. It also involved a serious menace to public health, inasmuch as food products and drugs, particularly meat, were commonly sold which were impure, diseased or otherwise wholly unfit for human consumption. The grossness of the abuses which developed resulted in the enactment of laws both by the national government and the States.

Federal Pure Food and Drug Acts.—In legislating upon this subject Congress was confronted by certain constitutional obstacles. Under our Federal system of government Congress has only such powers as are conferred upon it by the express words of the Constitution or which may be reasonably implied from the powers thus expressly granted. The Constitution gives Congress no authority to legislate upon the subject of food and drugs nor to regulate the processes of manufacturing. Obviously, therefore, it was impossible to pass a Federal law dealing in a direct and straightforward manner with the evils of adulteration and misbranding. Congress does, however, have full power to regulate interstate commerce and this authority was used as the constitutional basis of the national Pure Food and Drug Act. This act, signed by President Roosevelt 30 June 1906, does not forbid the production of adulterated and misbranded food products and drugs, except in the Territories and the District of Columbia where the authority of Congress is supreme, but merely forbids the distribution in interstate trade of such products as are fraudulent or unhealthful according to standards provided for in the law.

The principal provisions of the law are as follows: (1) It is unlawful to ship or receive in interstate or foreign commerce any adulterated or misbranded food or drugs. (2) The Secretary of the Treasury, the Secretary of Agriculture and the Secretary of Commerce and Labor shall make regulations for putting the act into effect, including the collection and examination of specimens of food and drugs. (3) Examinations of such specimens shall be made in the Bureau of Chemistry of the Department of Agriculture to determine violations of the act. (4) Drugs are to be regarded as adulterated if they are sold under a name recognized by the United States Pharmacopoeia and differ from the standards of strength, purity or quality therein laid down, except in cases in which the standards of strength, quality and purity are plainly marked. Drugs are also adulterated if their strength or purity is less than the professed standard under which they are sold. (5) Food is adulterated, first, if anything has been mixed or packed with it which reduces its quality or strength; second, if any substance has been substituted for it in whole or in part; third, if any valuable ingredient has been wholly or partially removed; fourth, if it has been mixed, colored, powdered, coated or stained so as to conceal damage or

inferiority; fifth, if it contains any added poisonous or injurious ingredient which may render it harmful to health; sixth, if it consists in whole or in part of filthy, decomposed or putrid animal or vegetable substance or any part of an animal unfit for food, or if it is the product of a diseased animal, or one that has died otherwise than by slaughter. (6) Drugs are regarded as *misbranded* if the packages or labels contain false or misleading statements regarding the contents or place of production, if they are imitations of or offered for sale under the name of another article, if the original contents of the packages have been changed since they were labeled, if the label does not indicate the quantity or proportion of alcohol, morphine, cocaine and other narcotics, and finally, by an amendment passed in 1912, if the label contains false statements regarding the curative or therapeutic effects of the contents. (7) Similar provisions cover the misbranding of food which must also, under an act of 1913, be marked with the measure, weight or numerical count save in the case of very small packages, and must not be labeled or branded in such a way as to deceive or mislead the purchaser.

The Meat Inspection Act.—This act was also passed 30 June 1906 and aims to provide special protection against the distribution in interstate commerce of unwholesome meat or meat products. Animals must be inspected by government officials before they are killed, the carcasses must be again inspected afterward, meats which are packed or canned must be further inspected and marked, and the establishments in which meat is killed, packed or in any way prepared must also pass close scrutiny. The government pays the cost of these inspections. To prevent corruption on the part of the inspectors they are frequently shifted from one part of the country to another on short notice. The administration of the law is in the hands of the Secretary of Agriculture who utilizes for that purpose the Bureau of Animal Industry. The beneficial results of these laws have been enormous. A large number of dishonest and injurious products have been driven from the markets forever to the great advantage of the pocketbook and health of the consumer. Manufacturers and producers have come to realize the commercial advantages of purity and cleanliness and have in numerous cases been glad to advertise the fact that they have gone far beyond the requirements of the law in those particulars. The commercial incentive to fraud and adulteration has thus been largely removed.

State Laws.—Since the pure food and drug laws of the national government are limited in their scope to the products which are distributed through interstate commerce it is only natural that the separate states should have legislation upon the same subject. Several facts should be noted about these State enactments. First, they apply to production, sale or distribution of food and drugs within the State. Second, they are in many cases more comprehensive in scope and more rigorous in the standards set up than the Federal laws. Third, they must be so drawn as not to produce a conflict with the Federal laws in their application or administration. For example, a State, under the guise of passing a law for the protection of

the health of its citizens, may not forbid the importation and sale within its borders of food or drugs in their original packages which meet the tests of the Federal law in the matter of purity or labeling. Few conflicts of this kind, however, occurred and the legislation of the Federal government and the States upon this important subject have merely supplemented each other.

ROBERT EUGENE CUSHMAN,
Associate in Political Science, University of Illinois.

PURGATIVES, cathartics; medicines for evacuating the bowels. See CATHARTIC; CONSTIPATION.

PURGATORY, according to the doctrine of the Roman Catholic Church, a state or place in which the souls of those who depart this life in the grace of God suffer for a time, in expiation of their venial transgressions or in undergoing the penalty due to mortal sins, the guilt and eternal punishment of which have been remitted. Hence purgatory is not a place or state of probation; for the souls in purgatory the time of probation is past, and they are already assured of their everlasting bliss in heaven, though as yet they are not sufficiently pure and holy to be admitted to the vision of God. The dogmatic teaching of the Church goes only so far as to declare that, (1) there is a purgatorium (place of purification), and (2) that the souls therein are aided by the prayers of their brethren on earth. But though the definitive teaching of the Church stops here, the speculations of divines, the meditations of spiritual men and the beliefs of the general mass of the faithful go much further, and have developed an idea of purgatory which is very much more definite. Thomas Aquinas and Suarez, among the greatest lights of the theological schools, teach that instantly after passing out of the present life, the faithful souls are cleansed from the stains of all venial sin by their turning with perfect love to God; at the same time the debt of the temporal penalties of sin, whether mortal or venial, has still to be paid. Theologians formerly taught that the purgation was by material fire, but this view has been widely modified. While confessedly the doctrine of purgatory is not clearly and unequivocally deducible from any passage of the universally accepted books either of the Hebrew or the Christian Scriptures (for Macabees is not received by all as canonical, and passages of the New Testament which Catholics believe to point decisively to this doctrine have no such signification for Protestants), it is admitted on all sides that in the very earliest church liturgies that are extant are found forms of prayer for the dead, and that the existence of an intermediate state after death is taught by the fathers both Eastern and Western with

practical unanimity, so far at least as to admit that the dead can be aided by the prayers of the living. Buddhists, Theosophists and many others teach of a region where discarnate souls are purified before they can go higher.

PURIFICATION, in the Jewish ceremonial law, a body cleansing with water accompanied by rites more or less elaborate according to the nature of the uncleanness from which the person was to be purified: this physical cleansing being regarded as emblematical of an inward spiritual purification. For different occasions of purification and different rites, see Leviticus xi, 25-40; xv, 1-15; xv, 18; Numbers xix. Similar rites of purification are common to pagan religions whether of ancient or modern times. In the ritual of the Roman Catholic Church, the rinsing of the chalice after communion and the ablution of the fingers of the celebrant after the same are called a purification.

PURIFICATION OF THE BLESSED VIRGIN MARY, Feast of the, a festival observed in the Roman Catholic Church on 2 February; in the calendar of the Episcopal Church in the United States, as well as in that of the Established Church of England, the Purification of the Virgin Mary is entered for the same day, and in the Book of Common Prayer there are collect and lessons for the day of "the Presentation of Christ in the Temple, commonly called the Purification of Saint Mary the Virgin." The events commemorated by the Church on this day are those recorded in the gospel of Saint Luke, ii, 22-39, namely, the going of the Virgin to the temple 40 days after the birth of her son, for her ritual purification after childbirth, according to the prescriptions of Leviticus xii; the presentation of the babe to the Lord; and the prophecies of Simeon and Anna. The Christian festival of the Purification was solemnized by the Church at least as early as the end of the 6th century. It is customary on this day, in Catholic countries, for the people and clergy to form processions, each one carrying a lighted candle, signifying the light which the Redeemer brought into the world.

PURIFYING APPARATUS, is of use in many industries and economic processes, particularly in the water supply of communities where the available source does not yield a pure product. Aside from the various chemical treatments of such waters the electrolytic system has found favor in that it purifies without adding some other ingredient. It has been found that certain metals are capable of producing, while under the action of an electric current immersed in the liquid to be purified, an insoluble hydroxide of the chlorides and sulphates held in solution, these being set free by the action of current passing through the liquid (see **ELECTROLYSIS**); the oxygen evolved at the anode decomposing and oxidizing impurities of animal and vegetable origin, leaving the water clear, free from odor and disease-breeding germs, sparkling, with a pure water taste (see **DISTILLATION**). For municipal supply, means are provided for the generation of electricity by either hydraulic or artificial power, using large basins containing the electrodes in which the oxidation takes place; the water passing thence

into a coagulating section provided with means to retard the suspended matters; the water flowing thence down an inclined weir for the purpose of aeration, into another compartment of the basin containing screens, which clarifies it from all sediment, thence to storage reservoirs, occupying small space as compared to sand bed filters and automatic in operation. The apparatus for potable and industrial use consists of vessels capable of working under high pressure as for boiler feed purposes, one of which contains the electrodes or a series of them for very large supply; the electrodes being connected to a suitable source of electric supply, the vessels being provided with air-valves and insulators to prevent the grounding of the current, and connected to other vessels by suitable conduits to remove the suspended matters, thus permitting a constant flow of the water through the apparatus, requiring small space and installed at any convenient point. For apartment-houses and hotels, and establishments for bottling carbonated waters small installations are quite efficient. They are arranged so that the motor may be run by the hydraulic pressure in the water main if desired. The current consumption is very low as the resistance of the water is utilized in the treatment.

In the gas industry the "purifier" consists of a number of sieve-like trays placed in tiers. These are filled with the purifying material and the gas is compelled to pass through them consecutively. In the first purifier the trays are filled with lime thiocarbonate and some sulphurets which remove the poisonous carbon dioxide, although increasing the content of sulphureted hydrogen. The second purifier contains slaked lime, and removes nearly all the carbon disulphide and part of the sulphureted hydrogen. The third purifier may be a duplication of the second, or, if the gas is not too foul, it may go at once to the last purifier, filled with iron oxide, which removes the last traces of the sulphides and sulphurets.

In the flour-milling industry the purifying apparatus is pneumatic. After the grain has been through the fourth pair of breaking rolls and is in the form known as semolina, ready to be ground into flour, it is passed through the purifier, a long silk-covered sieve of varying meshes, enclosed in an air-tight compartment. The sieve dips downward on a slight grade and is shaken by appropriate machinery. At the top of the purifier is an exhausting fan which sucks a draught of air up through the sieve and the "semolina" which is traveling down the grade upon the silk. The chaff and light fibrous material which has no food value is carried off into side channels by the draught, while the heavier food parts of the grain continue down the sieve until they come to a mesh which they can pass through, being thus sorted as to size for further treatment. The material removed by the draught amounts to from 10 to 15 per cent of the grain. This is again passed through a purifier of somewhat different weave, and a part of it is recovered and added to the semolina to be ground. The purifying chamber is provided with glass windows through which the process may be watched, and the arrangement of fan and air valves is such that the force of the draught may be adjusted with the greatest delicacy.

PURIM, poo'rim, the Festival of Lots, which was instituted by Mordecai (Esther ix, 27-x, 3), and is celebrated to this day by the Jews on the 14th and 15th of the month Adar (March), in commemoration of their wonderful deliverance from the destruction with which they were threatened by Haman. On these festive days the book of Esther is read, presents are interchanged, and gifts are sent to the poor. The great popularity of this festival in the days of Christ may be gathered from the following remark of Josephus: "Even now all the Jews that are in the habitable earth keep these days as festivals and send portions to one another." It is supposed that it was this feast which Jesus went up to celebrate at Jerusalem (John v. 1). It is universally celebrated by the large Hebrew population in the United States. See **BEFANA**.

PURITAN CITY, a name applied to Boston, Mass., referring both to the early settlers and the characteristics of its modern inhabitants.

PURITANISM. The Puritans were those who thought that the English Reformation had not gone far enough in its separation from the Roman Catholic Church, but that there were many ceremonies and forms still retained in the worship which were too suggestive of papacy. They held that it was not expedient or right to retain the use of the cross in baptism, the clerical vestments, the custom of kneeling at the altar and other forms which had been rejected by the Reformed Churches on the Continent. They believed that the worship should in this way be purified and that only those who lived upright lives should be the ministers of the Church. To them the Church was a means of advancing religious truth, and it could not do this to the best advantage while hampered, as they thought, by useless, misleading and unscriptural forms and ceremonies, especially when these forms and ceremonies were obligatory for all and the observance of them enforced by the civil authority. During the persecution of the Protestants in the reign of Mary, hundreds of the English reformers went to the Continent and were in the company of the leaders of the Reformed Church. When Elizabeth came to the throne, these men returned and became the leaders of English Protestantism. Some of them regarded the wearing of the vestments prescribed by the Church authorities as a matter of indifference, others refused to wear them. They did not object to the government of the Church of England or the close connection between Church and State or the doctrinal system, but objected to what they regarded as the remnants of popery.

Whether they would be allowed to do as they wished or not depended largely on the attitude of the queen. Elizabeth was a woman whose religious tastes were stronger than her religious convictions and the simplicity and bareness of the worship of the Reformed Church offended her. She disliked Puritanism because the teachings of men like John Knox opposed her idea of the royal power. She opposed any puritanical modification of the Prayer Book or of the ceremonies of the Church. That there was to be no room for nonconformity was shown when her first Parliament passed the Act of Uniformity,

which made unlawful any form of public worship but that of the Prayer Book, and the Act of Supremacy, by which the queen was acknowledged supreme governor of the realm in spiritual and ecclesiastical affairs. She resolved to retain in the worship as much show and form as possible, and ordered uniformity in vestments. If any refused they were forbidden to preach and deprived of their office. This law was not strictly enforced at first, but with greater rigor as the time went on. Large numbers were ejected from their churches, but continued to hold private meetings. Many were imprisoned and treated with severity. But nonconformity continued to grow notwithstanding the efforts to suppress it.

In early Puritanism the objection is mainly to the forms and ceremonies in the worship of the Church. In the later years of the reign of Elizabeth, attention is given to the government of the Church and the relation between Church and State. Elizabeth claimed that in this her will was supreme. Some of the Puritans, above all others, Thomas Cartwright, taught that the only right form of Church government was that laid down in the New Testament and that it was Presbyterianism. He taught that the civil authorities are not to interfere in Church affairs, but they are bound to protect it. There is still to be a state church but with a Presbyterian rather than an Episcopal form of government. This was directly opposed to the queen's supremacy, and her efforts to suppress this form of Puritanism were vigorous. These Puritan movements were within the Established Church, but there were some who believed that a church having any connection with the state was unscriptural and so there arose the party called Independents or Separatists. They taught that the local church was independent and should manage its own affairs. These were also called Brownists from Robert Browne, who was their first leader. The Separatists were severely persecuted and many left the country. Thus, at the close of the reign of Elizabeth, there are three kinds of Puritans: those who desire a purified worship and still remain in the Church, those who would have a state church under the Presbyterian form of government and those who believed that an established church was wrong. Hopes were entertained that James VI, educated in Presbyterian Scotland, would be more favorable to Puritanism. The clergy petitioned him for freedom from the burden of human rites and ceremonies and the matter was considered at the Hampton Court Conference. But James' motto was "no bishop, no king," so they could look for little toleration. Uniformity was enforced with great vigor and many Puritans deprived of all hopes of redress left the country. This condition continued with even greater severity in the reign of his son, Charles I, and there seemed in the early part of his reign no check on his tyranny in Church and State. Despairing of freedom in Old England, Puritan and Separatist turned to America to create there a New England. In 1620 a little company of Separatists after a sojourn in Holland came to America and settled at Plymouth. In the course of the next 20 years thousands of Puritans settled in Massachusetts. This Puritan

emigration stopped in 1640, when there seemed a better prospect of liberty in England. The Puritan emigrants came as members of the Church of England with no desire to separate. The Pilgrims were already separated from the English communion and were independent in their church government. But the Puritans because of their distance from the home country and because of the influence of the Pilgrims very quickly adopted the Congregational or Independent form of church government. Modern American descendants of the Puritan settlers regard them as having been far too strict. Their so-called "blue" laws are spoken of as indicating religious bigotry and intolerance.

PURITANS. See PURITANISM.

PURKINJE'S FIGURES, in optics, figures produced on a wall of uniform color when a person entering a dark room with a candle moves it up and down approximately on a level with the eyes. From the eye near the candle an image of the retinal vessels will appear projected on the wall.

PURPLE. A color located in the spectrum produced on a wall of uniform color when a person entering a dark room with a candle moves it up and down approximately on a level with the eyes. From the eye near the candle an image of the retinal vessels will appear projected on the wall. It is poetically termed the royal color. The ancients attributed the discovery of purple to the Phœnicians. The story of its having been discovered by a dog biting a purple-fish, and thus staining his mouth, is well-known. The purple-fish was found not only on the Phœnician coasts, but in all other parts of the Mediterranean, so that the use of it in dyeing came to be common with other nations. The modern discovery of purple colors from coal-tar makes an important epoch in the history of the dye. Painters in oil and water-colors produce various shades of purple by mixing certain red and blue pigments. For work in oil, French ultramarine, often called French blue, is mixed with vermilion or some madder red (madder carmine is best), or one of these reds with cobalt blue if a pale purple is wanted. For permanent purples in water-colors the same blues are used; but one of the madder reds, not vermilion, should be mixed with them. A much richer purple than any of the above mixtures will give is produced by Prussian blue and one of the lakes from cochineal—namely, carmine or crimson lake—but it is not permanent. This purple, as well as that obtained by mixing Indian red with indigo, also fugitive, was much used by water-color painters in past years. Purple madder is the only simple purple pigment available for the artist which is durable, and it is unfortunately costly. All purples are changed to neutral and gray tints by the addition of any yellow pigment. For house-painting maroon lake with a little French blue gives a useful purple. See DYES; PURPLE SHELL.

PURPLE-FACED MONKEY. See LANCUR; WANDEROO.

PURPLE FALCON, Order of the. See ORDERS, ROYAL.

PURPLE FINCH, a handsome American finch (*Carpodacus purpureus*) which in some one of its varieties is known throughout the United States and Canada. The male exhibits in spring a plumage beautifully tinged with a purplish crimson; and sings a brilliant melody. These birds nest in orchard trees and similar places, and lay greenish speckled eggs. See FINCH.

PURPLE MARTIN, one of the large, lustrous, blue-black swallows of the genus *Progne*, several species of which inhabit South and Central America, while one (*P. subis*) is a familiar visitor in summer to almost all parts of the United States. They originally nested in hollow trees, but in both North and South America have at once associated themselves with mankind as soon as civilization approached their habitat, and now everywhere make their nests about buildings or in garden bird-boxes. They are among the most useful as well as interesting of our insect-hunting birds. See MARTIN.

PURPLE SCALE. See SCALE INSECTS.

PURPLE SHELL, a gastropod mollusk of the family *Muricidae* and especially of one section of it of which the genus *Purpura* is typical. A great many species are found in all seas. The true purples form the subfamily, *Purpurinae*. The *Muricidae* are carnivorous marine snails very destructive to other mollusks, barnacles, etc. Many of the tropical species of *Murex* and related genera are of large size and remarkable for the large spines borne upon the shells, but our representatives of the family are small and inconspicuous. (See DRILL). Our true purple shell (*Purpura lapillus*) is found in great abundance on rocky coasts on both sides of the north Atlantic, but is infrequent in the United States south of Long Island Sound, where it is replaced to some extent by related species. The shell is very thick and solid, short oval with a low spire and a large aperture, the outer lip of which is marked with revolving ridges. It is extremely variable in size, shape, color and markings. Like the drill it is carnivorous, but with us confines its attacks chiefly to the barnacles which encrust the rocks between tides, though in Europe it works great havoc on the mussel beds.

The name "purple shell" applied to this group of mollusks is derived from the use to which certain species were put by the ancients in the preparation of their most valued dye-stuffs, for which the city of Tyre was especially famous, and upon which its prosperity about 1000 B.C. was founded. The Tyrian purple were of several shades, varying from blue to dull crimson, dependent upon the particular variety of shell employed and the substance mixed with the extract. Among the most important species utilized were *Murex trunculus*, *M. brandaris* and *Purpura patula*. These snails were gathered on both the African and European shores of the Mediterranean. The smaller ones were crushed in mortar-shaped holes in the rocks and mixed with soda, urine, sea-water and other substances; the larger animals were removed from their shells or the dye squeezed out. The desired colors were obtained by exposure to the sun and by various combina-

tions and the cloth was steeped in a large excess of fluid until the proper effect had been produced. The fluid is contained in a saccular gland which opens into the mantle cavity and has at first the color and consistency of cream and a disagreeable odor, but changes to purple upon exposure to light. Consult Simmonds, 'Commercial Products of the Sea.'

PURPURA. See PURPLE-SHELL.

PURSER, the cashier or chief clerk on board a passenger steamer. In the navy a purser was formerly an officer who took charge of the provisions of a ship of war and saw to their distribution among the officers and crew. He had very little to do with money matters, but generally bore an evil reputation among the sailors for unfair dealing and rapacity. The designation is now discarded for that of paymaster, whose duties are broader.

PURSLANE, a pot-herb and well-known weed forming a good fodder for pigs; often called 'pussley.' See PURTULACA.

PURSIVANT, *pér'swi-vant*, a title used in the heraldry of England, Scotland and Ireland and derived from the old Latin word "prosequere" to follow. It is the lowest of heraldic offices, but from the pursuivants were usually selected the superior officials known as herald and king-at-arms. The English college of arms has four pursuivants, the Scottish heraldic establishment has three and the Ulster king-at-arms in Ireland has four.

PURU-PURUS, *poo-roo'-poo-roos'*, or **PURU PULAS**, a tribe of Brazilian Indians, now extinct or represented only by the Pamary or Paumary, but formerly living along the Purus River (q.v.) in western Brazil. They were naked savages, who slept on the sand instead of in hammocks, and were afflicted by a leprous disease which covered them with bluish and whitish spots. They used practically no shelter or covering, except leaf umbrellas, and wore their hair long and unkempt, cut only on the forehead in a square bang. Linguistically they seem to have been separate from the surrounding peoples. Consult Brinton, 'The American Race' (1891).

PURUANDIRO, *poo-roo-än-dê-rô*, Mexico, a town of the state of Michoacán and capital city of the district of Puruandiro in central Mexico, situated on the southern shore of a small lake, about 42 miles northwest of Morelia. It does a large business in Mexican leather and in the agricultural produce of the surrounding country. Pop. 10,000.

PURURAVAS, in Vedic mythology a king of ancient India, son of Ilā, a youth of many virtues, who is married to Urvasī, one of the celestial nymphs, Apsarases, usually loved by the Gandharvas. Urvasī's marriage to Pururavas is based on the condition that she shall never see him naked. The jealous Gandharvas cause a disturbance in the night and Pururavas springs up, whereupon the Gandharvas cause a flash of lightning to illuminate the room and Urvasī sees him and vanishes. Pururavas, disconsolate, seeks the world over for her and at last discovers her in the form of an aquatic bird, swimming with other Apsarases in a lotus lake. In response to his pleadings Urvasī promises that he may return to her for one night a year later. Pururavas keeps the tryst

and on the following day the Gandharvas make him one of themselves. Another version is that Urvasī spends four autumns among mortals and is besought by her lover, Pururavas, to return, but refuses; promising, however, that his offspring shall worship the gods and that he himself shall enjoy heaven. Consult Macdonell, A. A., 'Vedic Mythology' (Strassburg 1897).

PURUS, *poo-roos'*, an affluent of the Amazon, which rising in the east of Peru traversing the northwest corner of Bolivia and entering Brazil, a northeastward course of over 1,800 miles, joins the Amazon about 100 miles above the latter's confluence with the Madeira. It has a very winding course and a comparatively slight fall. In the flood season it is navigable almost throughout its length and steamers ascend it for over 800 miles. Chief among its numerous tributaries is the Acre. Its source was discovered in 1864 by Chandless, an English explorer. Throughout most of its course the shores of the Purus are covered with dense forests in which are to be found but few inhabitants. Those who are living there are, for the most part, native Indians.

PURVER, *pér'ver*, Anthony, English translator: b. Hurstbourne, Hampshire, 1702; d. Andover, Hampshire, July 1777. He was at first apprenticed to a shoemaker, but mastered Hebrew, and at 20 opened a school. Later he went to London where he became a Quaker and there began his translation of the Bible in 1733, a task which occupied him for 20 years. It was completed in 1763 and published under the title 'A New and Literal Translation of all the Books of the Old and New Testament' (1764). The publication was known as the 'Quaker's Bible' and by many was pronounced crude and unscholarly, while warmly approved by Southey and other critics. He also published 'Youth's Delight' (1727); 'Poem to the Praise of God' (1748), and 'Counsel to the Friend's Children' (1785).

PURVES, *pér'ves*, George Tybout, American clergyman: b. Philadelphia, Pa., 27 Sept. 1852; d. New York, 24 Sept. 1901. He was graduated from the University of Pennsylvania in 1872 and from the Princeton Theological Seminary in 1876. He was pastor at Wayne, Pa., 1877-80, and professor of New Testament literature and exegesis at Princeton Theological Seminary 1892-1900. In the last-named year he accepted a call to the Fifth Avenue Presbyterian Church, New York. He wrote 'The Testimony of Justin Martyr to Early Christianity'; 'The Apostolic Age,' etc.

PURVEY, *pér'vi*, John, English Biblical translator: b. Lathbury, Buckinghamshire, about 1354; d. about 1427. While associated with Wyclif, whose disciple he became, he undertook with other scholars the revision of the translation of the Bible made by Wyclif in 1380. The revision was substantially a new work merely based on Wyclif's copy which had retained many Latinisms from the Vulgate. The new translation, on the other hand, was made in good idiomatic English. It was completed about 1388, four years after Wyclif's death. For his Wyclifite views he was imprisoned in 1390, recanted to escape martyrdom in 1401, and for two years was vicar of West Hythe, Kent. Purvey wrote against the corrup-

tion of the Church a work entitled 'Ecclesiaz Regimen.' Consult Leachler, 'John Wyclif and his English Precursors,' translated by Lorimer (1884).

PUS. See SUPPURATION.

PUSEY, pū'zi, Caleb, American Quaker colonist: b. Berkshire, England, about 1650; d. Chester County, Pa., 25 Feb. 1727. He was educated a Baptist, but joined the Quakers and came with Penn's company to America in 1682, erected the first mills in the province known as the "Chester Mills," and of which Penn himself laid the cornerstone. He laid out roads, treated with the Indians, was sheriff of Chester County for two years, justice of the peace and of the County Courts for many years, an associate justice of the Supreme Court and for 10 years a member of assembly. He published a great number of pamphlets and articles in defense of his creed, among them 'A Serious and Seasonable Warning' (1675); 'A Modest Account from Pennsylvania of the Principal Differences in Point of Doctrine between George Keith and those of the People called Quakers' (1696); 'Saturn's Harbingers Encountered' (1700), etc.

PUSEY, Edward Bouverie, English scholar and theologian: b. near Oxford, 22 Aug. 1800; d. Ascot Priory, Berkshire, 16 Sept. 1882. He was a son of the Hon. Philip Bouverie (of the Radnor family), who assumed the name of Pusey by royal license on becoming lord of the manor of that name in Berkshire. He was educated at Eton and Oxford University, where he was graduated with first class honors. Soon after he was elected to a fellowship at Oriol College. He studied for two years in Germany, taking up more especially Oriental languages, theology and German, and in 1828 was appointed regius professor of Hebrew, a post which he retained all his life, and to which a canonry at Christ Church is attached. In 1826 he had published a book summarizing the progress of German theological thought since the Reformation, expounding the rationalistic views regarding religion which were common in Germany, his account of which was founded on his own personal experience of what he believed to be the evils of Rationalism. He became through the influence of his friends Hurrell, Froude and Newman an ally of the theological party who started the Tracts for the Times (see TRACTARIANISM), but the agitation had been going on a little time before he took an active part in it. His first tract was the 18th, 'On the Benefit of Fasting'; he subsequently wrote another (the 66th) on the same subject, and two (the 67th and 69th) 'On Holy Baptism.' In connection with the same High Church movement he undertook the joint-editorship of the 'Library of the Fathers' and the 'Library of Anglo-Catholic Theology.' In 1843 he was suspended from preaching in the university pulpit for three years on account of a sermon on the Eucharist, in which he advocated the doctrines of the real presence, sacerdotal absolution and of the duty and privilege of confession. Except for literary labors and occasional sermons, Dr. Pusey's life was henceforward an uneventful one. Among his chief works are a treatise on 'The Ancient Doctrine of the Real Presence'; 'Letters to the Archbishop of Canterbury in Defence of Church

Principles'; a treatise on 'Marriage with a Deceased Wife's Sister'; a 'History of the Councils of the Church' (1857); a learned 'Commentary on the Minor Prophets' (1860-77), an important contribution to Hebrew scholarship. Nine lectures on 'Daniel the Prophet' (1864), and 'The Church of England, or Portion of Christ's Holy Catholic Church: an Eirenicon' (1865). As a leader of the Tractarian or High Church party he kept a large section of that party from drifting into the Catholic Church and remained unshaken in his fidelity to the church of his baptism. On this ground, perhaps, the party received the popular name of Puseyites. Pusey House, containing his library, was founded and endowed as a memorial to continue the tradition of his teaching. Consult Liddon, 'Life of Edward Bouverie Pusey' (5 vols., 1893-99); Grafton, 'Pusey and the Church Revival' (1902); Rigg, J., 'Character and Life-Work of Dr. Pusey' (1883); Savile, B. W., 'Dr. Pusey, an Historic Sketch, with Some Account of the Oxford Movement' (1883).

PUSEYISM. See OXFORD MOVEMENT, THE

PUSHKIN, poosh'kin, Alexander (spelled also POUCHKIN, POUCHAKIN), Russian poet: b. Moscow, 26 May (7 June) 1799; d. Saint Petersburg, 29 Jan. (10 Feb.) 1837. He received his first education in the Lyceum at Tsarskoë-Selo. In 1817 he entered the service of the government in the Ministry of Foreign Affairs, in 1820 was retired to southern Russia because of his liberal opinions, until 1824 was a subordinate in the office of the governor-general of Odessa, angered his superior by an epigram and was withdrawn wholly from the service and ordered to live on his estate of Mikhailovskoë. In 1826 Nicholas I allowed his return to Saint Petersburg, where he was made imperial historiographer. His only work of research however, was the 'History of the Revolt of Pugachev'; he labored in the archives on an account of Peter the Great, which came to nothing. He died from a wound received in a duel, and the Tsar appropriated 150,000 rubles to settle his affairs and publish his works. These included, above all, 'Eugeni Onyegin' (1828), a metrical narrative in a somewhat Byronic fashion; and 'Boris Godunov,' a tragedy dealing with the troublous period following the death of Tsar Feodor. Pushkin performed a great service for the Russian language and literature; molding the former which prior to his time was uncouth and unwieldy, and freeing the latter from its French tradition and placing it solidly upon a native basis. He has been called "undeniably and essentially the great national poet of Russia." There are English renderings of 'Eugeni Onyegin' (by Spalding, 1881); of the 'Poems' (by Panin, 2d ed., 1888); and of the 'Prose Tales' (by Keane, 1896). A memorial work, 'Translations from Pushkin,' by Turner, appeared in 1899. Consult Shaw, 'Sketch of Pushkin's Life and Works' (1845); Flach, 'Un Grand Poète Russe' (1894). See BORIS GODUNOV, EUGENI ONYEGIN.

PUSS IN BOOTS, a well-known nursery tale by Charles Perrault, whose version, 'Le chat botté' appeared in his 'Contes de Fées' (1697). It was probably taken from Straparola's 'Piacevoli Notti.' The story is found

in a Norse version in 'Lord Peter,' and in the Swedish 'Palace with Pillars of Gold,' in which the cat befriends a girl, whose adventures are similar to those of the Marquis of Carabas. In a Sicilian version is found the first hint of a moral which is lacking in the above-mentioned tales; that is, the ingratitude of the man. Cosquin imagined from the moral that its origin was Buddhistic, for the story could only have arisen in a comparatively civilized community; but the only Hindu version, the 'Match-Making Jackal,' discovered about 1884 in Bengal, has no moral at all. The most complete moral is found in Zanzibar, in the Swahili tale of 'Sultan Darai,' in which the beneficent beast is a gazelle; the ingratitude of the man is punished by the loss of all that he had gained; the gazelle, which dies of neglect, is honored by a public funeral. A well-known German version is that by Tieck, 'Der gestiefelte Kater,' 1795).

PUSTULES. See PIMPLES.

PUT YOURSELF IN HIS PLACE, a novel by Charles Reade, published in 1870. The scene is laid in an English manufacturing town, and the story narrates the struggles of Henry Little, workman and inventor, against the jealousy and prejudice of the trades unions. Like all of Reade's stories, 'Put Yourself in His Place' has a wealth of dramatic incident, and moves with dash and vigor. It is notable for its underlying purpose of exposing without censure the errors of early trades unions.

PUTCHOCK, pu-chok', or **PUCHUCK**, the root of *Aplotaxis lappa*, the "costus" of the ancients, a composite plant growing on the Himalayas in the vicinity of Cashmere. It has long lyrate leaves and heads of purple florets. It is exported to the Malay countries and to China, where it forms a main ingredient in the Chinese pastille-rods known as joss-sticks. In Upper India it is given as a medicine in various complaints ranging from coughs to cholera.

PUTLITZ, poot'litz, **Gustav Heinrich Gans, EDLER HERR VON UND ZU**, German novelist and poet: b. Retzin, Prussia, 20 March 1821; d. there, 9 Sept. 1890. He was educated at Magdeburg, Berlin and Heidelberg, was engaged in the civil service in 1846-48 and made his debut in literary circles by his comedies which aptly portrayed high social life and excelled in humor. In 1863 he was appointed director of the court theatre at Schwerin, and his collected dramas were published in 1850-69. His poems were characterized by much beauty and grace and his charming fairy poem 'Was sich der Wald erzählt' (1850) was widely circulated. His novels were also popular. Among his publications are 'Vergissmeinnicht' (1851); 'Brandenburger Geschichten' (1862); 'Novellen' (1863); 'Funken unter der Asche' (1871).

PUTMAN, Emily James Smith, American author and educator, daughter of Justice James C. Smith: b. Canandaigua, 15 April 1865. She was graduated at Bryn Mawr College in 1889 and studied at Girton College, Cambridge University, in 1889-90. She was teacher of Greek at the Packer Collegiate Institute, Brooklyn, in 1891-93; Fellow in Greek at the University of Chicago in 1893-94, and dean of Barnard College in 1894-1900. She was married to George Haven Putman (q.v.) in 1899.

She was a trustee of Barnard College in 1900-05, and vice-president and manager of the Women's University Club, New York, in 1907-11. In 1901-04 she was president of the League for Political Education. Author of 'Selections from Lucian' (1891); 'The Lady' (1910); 'Greek Religion' (1913).

PUTNAM, püt'nám, **Frederick Ward**, American archaeologist and ethnologist: b. Salem, Mass., 16 April 1839; d. 1915. He became curator at Essex Institute in Salem in 1856, was graduated from Harvard in 1862 and in 1864 became director of the Essex Institute Museum. In 1867 he was appointed superintendent of the East Indian Marine Society's Museum at Salem and in 1875 was appointed civilian assistant on the United States surveys west of the 100th meridian, his duties being to make investigations and reports of the archaeological and ethnological material collected. In 1876-78 he was in charge of the Agassiz collection of fishes at the Museum of Comparative Zoölogy and in 1886 was appointed professor of American archaeology and ethnology at Harvard. He was chief of the department of ethnology at the World's Columbian Exposition in 1893. He is author of numerous pamphlets on scientific subjects, was one of the founders and editors of the *American Naturalist*, and has edited many volumes of 'Annual Reports of the Trustees of the Peabody Museum of Archaeology and Ethnology' and 'Proceedings of the Essex Institute.'

PUTNAM, George Haven, American publisher and author, son of G. P. Putnam (q.v.): b. London, England, 2 April 1844. He was educated in New York, Paris and Göttingen, leaving the university at the latter place to enter the Union army as a volunteer in 1862. He served through the war, was a prisoner at Libby in the winter of 1864-65, and attained rank as major of volunteers. He is head of the firm G. P. Putnam's Sons, was a leader in reorganizing the American Copyright League in 1887 and was instrumental in securing the passage of the copyright bill in 1891. He has published 'Authors and Publishers' (1883); 'The Artificial Mother' (1894); 'Books and their Makers in the Middle Ages' (1896); 'The Censorship of the Church' (1906); 'Abraham Lincoln' (1909); 'Memories of a Publisher' (1915).

PUTNAM, George Palmer, American publisher and author: b. Brunswick, Me., 7 Feb. 1814; d. New York, 20 Dec. 1872. He entered the book store of Jonathan Leavitt in New York in 1828, became a member of the firm Wiley and Putnam in 1840 and in 1841 went to London where he conducted a branch business. In 1848 he returned to New York, opened a publishing house, engaged in the production of finely illustrated books and established *Putnam's Magazine* 1853-56, which was resumed in 1868 and afterward merged with *Scribner's Monthly*. In 1866 he established the publishing firm now known as G. P. Putnam's Sons. He was an ardent advocate of international copyright reform, secretary for many years of the Publishers' Association, a founder of the Metropolitan Museum of Art, and wrote 'A Plea for International Copyright' (1837); 'Chronology' (1833); 'The Tourists in Europe' (1838);

'American Facts' (1845); 'The World's Progress' (1850); 'Ten Years of the World's Progress' (1861), etc.

PUTNAM, Herbert, American librarian: b. New York, 20 Sept. 1861. He was graduated at Harvard (1883); studied law at Columbia (1883-84), and was admitted to the bar (1886). He received also the degrees of Litt.D. from Bowdoin (1898), LL.D. from Columbia (now George Washington University, 1903), University of Illinois (1903), University of Wisconsin (1904), Yale (1907), Williams (1911), Litt.D. from Brown (1914). From 1884-87 he was librarian at the Minneapolis Athenæum, and at the Minneapolis Public Library (1887-91). After this he practised law at Boston (1892-95), and became librarian at the Boston Public Library (1895-99). Since March 1899 he has been librarian of Congress. He was twice president of American Library Association (1898, 1904). Numerous articles have been published by him in reviews and professional journals.

PUTNAM, Israel, American Revolutionary soldier: b. Salem (now Danvers), Mass., 7 Jan. 1718; d. Pomfret (now Brooklyn), Conn., 19 May 1790. His education was a desultory one. In 1740 he removed from Salem and purchased in that part of Pomfret, Conn., which is now Brooklyn, the farm where he afterward resided. It is said that he also hung out a shingle advertising entertainment for man and beast. There is also the well-known anecdote of the exploit in which he crept into the lair of a destructive wolf and there dispatched the animal. But little definite is known of Putnam's life until he is found in 1755 in receipt of a commission as captain of Connecticut volunteers in a regiment sent by the colony to aid in repelling a threatened French invasion of New York. He was present at the defeat of the French and Indians under Dieskau near the southern end of Lake George, and later was very successfully employed as a ranger and scout. In 1756 he commanded a company in Abercrombie's army, which had Crown Point as an objective, but was so outplayed by Montcalm as to be obliged to act rather defensively than offensively. He received a major's commission from the Connecticut legislature in 1757. During Abercrombie's expedition against Ticonderoga in 1758 Putnam commanded an advance guard and scouting party of 100. In the retreat following the rash and disastrous attack on the post he became aide to Abercrombie, replacing Howe, who had been shot. Having been sent out in August to capture from the enemy a large quantity of British stores, he was taken prisoner and tortured by the Indians, but rescued by a French officer. He was sent to Ticonderoga and thence to Montreal, where he was exchanged. Promoted lieutenant-colonel in 1759, he accompanied the force sent against Montreal, upon whose surrender Canada passed into English hands. In 1762 he commanded the contingent of 1,000 sent by Connecticut in the naval expedition against Havana. His vessel was wrecked off the Cuban coast, but those on board escaped by rafts, and took part in the successful attack on Havana. He was sent out against the Indians of the frontier, who, under Pontiac (q.v.), were menacing Detroit, in 1763. A peace was concluded; Putnam returned to

his farm, and there remained in retirement until 1775. When the news of Lexington reached him, he is said to have been plowing, Cincinnatus-like; and at once to have turned loose the oxen and ridden to Cambridge. A Connecticut regiment was forthwith organized, and Putnam, with a brigadier's commission, appointed to command it. In May he led a battalion to Noddle's Island, where he captured a sloop and burned a schooner of the enemy. He was a participant in the battle of Breed's (Bunker) Hill, which he had helped to fortify; the chief command in the action has been claimed for him against Prescott. Trumbull, in his picture in the Capitol at Washington, shows Putnam in brilliant uniform defending a gun. Commissioned major-general in July, he was placed in command at New York, and was ranking officer within the fortifications during the battle of Long Island. After having been stationed at Philadelphia, Crosswick and Princeton, he was sent in May 1777 to command in the "Highlands" of New York. Owing to the loss of Fort Montgomery and Fort Clinton, he was removed from his command; but later was restored on being acquitted by a court of inquiry. Subsequently, when he was commanding in Connecticut, Horseneck, an American outpost, was attacked by the British under Tryon. Putnam, according to the story, escaped by dashing on horseback down-hill, and eventually pursued the retreating Tryon, from whom he took 50 prisoners. In the winter of 1779 he was stricken with paralysis and incapacitated from further service. Consult 'Lives,' by Tarbox (1876), and Livingston (1901); Ober, 'Old Put, the Patriot' (1904).

PUTNAM, John Pickering, American architect: b. Boston, Mass., 1847. He was graduated from Harvard in 1868, studied later in the Ecole des Beaux Arts, Paris, and in the Royal Academy of Architecture, Berlin. He has since practised his profession in Boston and has published 'The Open Fire Place in All Ages'; 'The Principles of House Drainage'; 'Improved Plumbing Appliances'; 'The Outlook for the Artisan and His Art.'

PUTNAM, Mary Traill Spence Lowell, American author, sister of James Russell Lowell (q.v.): b. Boston, Mass., 3 Dec. 1810; d. there, 1 June 1898. She was married to Samuel R. Putnam in 1832 and later traveled abroad for several years. Her literary work was confined to magazine writing until 1844, when she translated from the Swedish Fredrika Bremer's 'The Handmaid.' She afterward published 'History of the Constitution of Hungary' (1850); 'Records of an Obscure Man' (1861); 'The Tragedy of Errors' and 'The Tragedy of Success,' a dramatic poem in two parts (1862); 'Fifteen Days' (1866); 'Memoir of Charles Lowell' (1885), etc.

PUTNAM, Rufus, American Revolutionary soldier: b. Sutton, Mass., 9 April 1738; d. Marietta, Ohio, 1 May 1824. He was apprenticed in 1754 to a millwright, but acquired some knowledge of surveying and later found employment in that profession. In March 1757 he enlisted as a private for service in the French and Indian War, and re-enlisted yearly until 1761, being made ensign in 1760. His story of the campaigns in which he served may be read in the 'Journal' which he kept

throughout. He was a farmer successively at New Braintree, Mass. (1761), Brookfield, Mass. (1765) and Rutland, Mass. (1780). In 1773 he went to Florida as one of an investigating committee appointed to examine lands granted by the Crown to Colonial soldiers and officers who had fought in provincial regiments during the French and Indian War. Putnam was made deputy-surveyor of Florida by the governor of the province and accompanied the expedition up the Mississippi to the Yazoo, up the Yazoo to Haines' Bluff, back to the Big Black and thence in return down the Mississippi. He planned and directed the construction of the Continental lines of defense at Roxbury and for the excellence of his work was detailed by Washington as acting chief engineer of the army. On 11 Aug. 1776 he was appointed by Congress chief engineer of the army, with colonel's rank; but preferring service in the field, he resigned in December and took command of the 5th Massachusetts Regiment. With the northern army in 1777 he did conspicuous service, particularly at Stillwater, where he headed the 4th and 5th regiments of Nixon's brigade. On 7 Jan. 1783 he was promoted brigadier-general. He was for several years a member of the Massachusetts legislature and during Shays' rebellion (q.v.) (1786-87) was a very efficient aide on the staff of Gen. Benjamin Lincoln. In March 1787 he was chosen (with Gen. S. H. Parsons and Rev. Manasseh Cutler) a director of the Ohio company, organized (1 March 1786) with a capital of \$1,000,000 in public securities, to be expended in the purchase of land in the Northwest Territory. In July a contract was made with Congress for one and a half million of acres and soon afterward an ordinance, familiarly known as the "Ordinance of 1787," was passed, providing for the government of the Territory. On 7 April 1788 Putnam, meanwhile made superintendent of the company, landed with a party of emigrants at the mouth of the Muskingum and on the present site of Marietta commenced the first organized settlement in the Northwest Territory. He concluded in 1792 at Vincennes a treaty with eight tribes of the Wabash Indians and in 1793 resigned his commission in the army. He was one of the judges of the United States court in the Territory, 1790-96, and from 1796 until his removal by Jefferson for political reasons in 1803 was surveyor-general of the United States. He was the founder of the first Bible society west of the Alleghanies (1812), a sturdy Federalist in politics and with the exception of Lafayette the last survivor of the general officers of the Continental army. Consult his 'Journal,' edited, with sketch by Dawes (1886). Putnam's papers, including the manuscript 'Journal' and correspondence with Fisher Ames, Trumbull, Washington and others are preserved at Marietta in the library of the college there; they were edited by Rowena Buell (1904) under the title 'The Memoirs of Rufus Putnam and Certain Official Papers and Correspondence.'

PUTNAM, William Le Baron, American jurist: b. Bath, Me., 12 May 1835. He was graduated from Bowdoin College in 1855, admitted to the bar in 1858 and engaged in law practice in Portland, Me., 1858-92. In 1887 he

accepted an appointment by President Cleveland as commissioner to settle with Great Britain the rights of American fishermen in Canadian waters and was also a member of the commission under the treaty of 6 Feb. 1896 between Great Britain and the United States. He had twice declined appointments as justice of the Maine Supreme Judicial Court, but in 1892 accepted an appointment as judge of the United States Circuit Court. In 1888 he was the Democratic candidate for governor of his State.

PUTNAM, Conn., city, one of the county-seats of Windham County, on the Quinebaug River, junction joint of New York, New Haven and Hartford main line and Norwich and Worcester branch, about 45 miles east by north of Hartford. It was incorporated from portions of the towns of Thompson, Killingly and Pomfret, by the State assembly in May 1855 and was organized as a municipality 3 July 1855 and in 1895 was chartered as a city. Near the centre of the city are Cargill Falls, noted for their beauty. It is the centre of an agricultural region and has a number of manufacturing interests. The chief industrial establishments are cotton and woolen mills, a tire fabric factory, silk mills, manufactories of heaters and castings and a toolmaking plant. The number of employees in the manufactories is about 2,200. It has the Day Kimball Hospital, Mother House of the Sisters of the Holy Ghost and seven churches and a Jewish synagogue. The educational institutions are a high school, State trade school, public and parish schools and a public library. There are two banks, one National, with a capital of \$150,000 and one savings and the business annually is over \$20,000. The government is administered under the charter of 1895, which provides for a mayor, who holds office two years, and a council of nine members. A board of three commissioners operates the municipally-owned water supply system. Pop. 9,000.

PUTNAM, Fort, a former Revolutionary fort at West Point, N. Y.

PUTS AND CALLS. See STOCK EXCHANGE.

PUTTENHAM, püt'en-am, George, English author: b. about 1530; d. about 1600. He is reputed to be the writer of a work entitled 'The Arte of English Poesie, contrived into three bookes; the first of Poets and Poesie, the second of Proportion, the third of Ornament,' which appeared anonymously in 1589. The Arte is a review of ancient as well as modern poetry and was written for the court. It shows considerable literary knowledge and no small critical power. Its author wrote several other pieces which have been lost. The authorship of 'The Arte' also has been claimed for Richard Puttenham, his brother.

PUTTIALA, püt-të-ä'lä. See PATIALA.

PUTTKAMER, poot'kä-mër, Robert Viktor von, Prussian statesman: b. Frankfort-on-the-Oder, 1828; d. Karzin, Prussia, 15 March 1900. He was educated at Heidelberg, Geneva and Berlin, entered government service in 1854 and as a friend and relative of Bismarck his rise was rapid. He was elected to the Reichstag in 1873 as a Conservative member and in 1877 was chief president of the province of

Sitiesia. In 1879 he became minister of education and public worship and endeavored to carry out the compact Bismarck had made with the Clericals. In 1881 he was appointed minister of the interior and vice-president of the ministry. He energetically enforced measures against the Socialist party and his methods in favoring the election of government candidates aroused the opposition of the Radicals and were bitterly attacked in a speech by Eugene Richter. After the accession of Friedrich III, Puttkamer resigned and though it was expected that he would be reinstated when Wilhelm II came to the throne, he was merely appointed chief president of Pomerania in 1891.

PUTTUN. See **PATTAN**.

PUTTY, a mixture compounded of whitening and linseed-oil, sometimes with a slight addition of white lead, beaten together to the consistence of a thick dough. It is used by glaziers for the purpose of fixing sheets of glass in the frames of windows, etc., and also by painters for filling up holes in the surface they are about to paint. It becomes very hard when dried. Plasterers make a so-called putty of ground white lime softened with water. Putty powder is tin dioxide, useful for polishing glass, etc.

PUTUMAYO, poo-too-mā'yō, or **ICA**, a South American river, rising in the southwestern part of Colombia on the eastern slope of the Cordillera. It flows southeast for about 1,000 miles, almost on the line of the equator in its midcourse, receives at the right the San Miguel and Yahuas and at San Antonio after about 150 miles in Brazil empties into the Amazon. It was explored by Reyes and Crevaux, is navigable within 100 miles of its source and promises to be a valuable commercial waterway between Brazil and Colombia. The name is also applied to the territory through which it flows, which was exploited early in the 20th century by an English syndicate. Sir Roger Casement headed an official investigation, which disclosed the utmost barbarity in collection of rubber from the natives. The company was driven out of existence. Consult Hardenburg, 'The Putumayo' (1912) and 'The Putumayo Red Book' (1914).

PUVIS DE CHAVANNES, Pierre, pē-ār pū-vēs dé shā-vān, French painter: b. Lyons, 14 Dec. 1824; d. Paris, 25 Oct. 1898. He sprung from an old Burgundian family of strong Catholic traditions. His father was an engineer and he himself was destined to the same career, but an intervening illness and a journey to Italy confirmed a predilection for painting. His first master was Ary Scheffer, with whom he studied but a short time and went for a second visit to Italy. Returning he put himself under the tuition first of Delacroix, then of Couture, but parted from each of them after a short period, as he had with his former master, from an inability to submit to any leading but his own artistic instincts. Certain marks of the influence of these men are seen by critics, particularly of Delacroix, even in the very latest products of Puvis' life. These may be traced in the more fundamental traits of his drawing, in the composition, spacing and the like. Others incline to the belief that his work

rather suggests the influence of his early visits to Italy, in a sort of reminiscence of the frescoes of Piero della Francesca. Such suggestions seem for the most part only an effort toward discovering subtle resemblances urged on by the really insistent originality of this artist's work. Working out his own theories which were at variance with all the ruling traditions of his day it is not wonderful that he should have encountered opposition. The Salon refused his work nine times. In 1861 came his first recognition when he gained a second-class medal and sold his pictures 'War' and 'Peace' to the state. These were placed in the Museum of Amiens to which the painter later presented the companion pieces 'Rest' and 'Labor.'

In 1872, as member of the Salon jury, he disagreed with his colleagues and resigned. He was made president of the Society of French Artists, holding their exhibition in the Champs de Mars and in 1877 was made officer of the Legion of Honor.

As a wall-painter he was the great leader of modern times in recognizing the limitations imposed by this branch of painting and in submitting himself to its demands. He saw that fresco was only the agreeable decoration of a wall surface, which should not attempt to conceal its character as a wall by sharp contrasts of light and shadow and elaborate arrangements of foreshortening and perspective. Consequently he painted in flat tones of cool green, blue, brown or lilac, having always in mind the relation of his designs to their architectural surroundings. His pictures themselves were essentially architectural in their arrangements. Among his mural decorations are those at Marseilles, Lyons, Lille and Poitiers, those in the hotels de Ville at Rouen and Paris, the Hemicycle of the Sorbonne in Paris, the series on Saint Genevieve in the Pantheon and the decorations of the staircase of the public library in Boston. In the last-named work he sought, as he himself stated, "to represent under a symbolic form and in a single view the intellectual treasures collected in this beautiful building." The whole seems to be summed up in the composition entitled 'The Muses of Inspiration hail the Spirit, the Harbinger of Light.' Apollo occupies the centre of this panel and the white-robed Muses, draped in filmy white, are ranged in mid-air against a background of pale green grass, with flowering bushes and slender trees, with the deep blue ocean and pale luminous sky stretching beyond. "Out of this composition," writes Puvis de Chavannes, "others have developed which answer to the four great expressions of the human mind, Poetry, Philosophy, History, Science." On the right-hand wall of the staircase as one enters appear in three panels: (1) Pastoral Poetry (Virgil); (2) Dramatic Poetry (Æschylus and the Oceanides); (3) Epic Poetry (Homer crowned by the Iliad and Odyssey). Consult Michel, 'Puvis de Chavannes' (1912).

PUY, Le, lê pū-è, France, arrondissement and capital city of the department Haute Loire. (1) The arrondissement, a little to the southeast of the centre of the department, has an area of 8,680 square miles and a population of about 145,716 and is divided into 14 cantons

and 115 communes. Its capital and that of the department is (2) Le Puy, or Le Puy-en-Velay, lying at the confluence of the Dolezon and the Born, on the sides and top of the Mont Anis (whence its mediæval Latin name of Anicium or Podium Anicense), so that its least elevation is about 2,500 feet above sea-level and its greatest, the volcanic dike called the Rocher de Corneille about 2,500. It is ill-built but picturesque. The Rocher de Corneille is topped by a statue of Notre Dame de France made from Russian cannon taken at Sebastopol. The city is a bishop's seat and has a cathedral at the top of a staircase with 136 steps; other important buildings are an old chapel of the Templars, known as Diana's temple, the Gothic church of Saint Michel d'Aiguille (962-984), the splendid marble and bronze Crozatier Fountain, and the Crozatier Museum, which is especially rich in exhibits of the industries of the town. These are chiefly laces, especially guipure, tulle, woollens, bells and clocks. Pop. 21,420.

PUY-DE-DOME, pü-ê-dé-dôm, France, a central department of the Auvergne, bounded on the north by Allier, on the east by Loire, on the south by Haute-Loire and Santal, and on the west by Corrèze and Creuse, and so named from the peak 4,086 feet in the Puy-de-Dôme group of volcanic mountains in the northern part of the department. The southern range, called Mont-Dore is higher, and the geology and mountain structure of the region is interesting. The highlands are excellent pastures; rye and oats grow at more moderate elevations; and vineyards, wheat, hemp and flax-fields cover the lowlands. The forest timber is valuable, as are the mineral waters and the coal deposits. Capital, Clermont-Ferrand (q.v.). Area 3,070 square miles. Pop. 525,916.

PUYALLUP, poo-yă'l'ûp, an American tribe, similar to the Nisqually family in Washington and Oregon. They formerly occupied all the region about the Puyallup River. A remnant of about 300 of them reside on a reservation near Tacoma.

PUYALLUP, Wash., city in Pierce County, five miles southwest of Tacoma, on the Puyallup River and on the Northern Pacific Railroad. The State Masonic Home is situated here and there is also a home for soldiers' widows. The surrounding district is largely devoted to raising raspberries and there is a canning factory and also lumber interests. Pop. 4,544.

PUZZOLANA. See CEMENT.

PYÆMIA (formerly suppurative fever, purulent infection, purulent diathesis, etc.), no longer means pus in the blood, but is a form of blood-poisoning (q.v.) of microbic origin, septic infection due to the absorption of pyogenic germs. The typical pathological condition is the production of multiple abscesses in tissues remote from the seat of injury, produced by living bacteria (forms of cocci probably) transported by the blood. Various experiments have shown that pus taken up by the blood-current does not produce pyæmia unless it contains virulent microbes. Sometimes the abscesses of pyæmia are metastatic or embolic caused by the lodgment of infected emboli in arterioles or veinlets, the inflammation of these vessels and its extension to surrounding areas. Formerly

when antiseptics was unknown it was quite common. At the present time pyæmia is infrequent, except where injuries are much neglected. Yet it may begin in the veins of the face and the sinuses of the cranium, from acute and chronic otitis media, etc. It may be associated with or precede septicæmia (a poisoning due to living bacteria in the blood), and death may result from the general infection of the system. Fortunately absorbed virulent microbes are sometimes killed or neutralized by leucocytes, by the chemical bodies called by Buchner sozins and alexins, by the tissue-cells of the liver, spleen, etc., or may be excreted in a living state by the glandular excretory organs. The onset of pyæmia is marked by depression of the vital powers, chills, fever, sweating, and sometimes jaundice; by a coated dry tongue, a rapid feeble pulse, a foul breath; by constipation, followed by foul-smelling loose movements and by scanty high-colored urine. When these symptoms follow a surgical operation or an injury, and abscesses are not so superficial as to be discovered, deep-seated ones are surmised.

The treatment is preventive and curative. See that the patient's power of resistance is not lowered. Keep the bowels and kidneys active. Intestinal putrefaction must not occur. Sunlight, good air and nourishing food are necessities. As yet no reliable serum-injection has been found to grant immunity. Wounds should be treated antiseptically, and abscesses be antiseptically opened, cleaned and drained. Stimulants, quinine and other tonics are indicated.

PYAT, pe-a, Felix, French journalist and politician: b. Vierzon, France, 4 Oct. 1810; d. Saint Gratien, France, 5 Aug. 1889. He studied law and was admitted to the bar in 1831, but confined his attention chiefly to literature and politics. He was an advocate of the attempted insurrection in 1849, a signer of Ledru-Rollin's appeal to the populace, and was forced to escape from France after the failure of the plan. He busied himself in forming further schemes for revolution, living successively in Switzerland, Belgium and England, and was a member of the "European revolutionary committee." When the general amnesty was granted in 1870 he returned to France, speedily attained leadership among the Paris Communists and was prominent in the destruction of the Vendôme column. The fall of the Commune rendered flight again imperative and for his part in the Communal government he was tried and placed under sentence of death in 1873, though then absent from France. He was pardoned in 1880, returned to France and in 1888 was elected deputy from Marseilles.

PYCNOGONIDA. See PANTOPODA.

PYDNA, pid'nä, in ancient history, a city of Pieria in Macedonia, originally on the west coast of the Thermaic Gulf, but removed three miles inland by Archelaus. The Athenians controlled it for a time, but lost it to Philip the Great. In 168 B.C. at the battle of Pydna, Perseus of Macedonia was utterly defeated by the Romans under Æmilius Paullus—the death-blow of the Macedonian empire. In Byzantine times the city of Kitron or Kitros grew up on the same site and this name is borne by the present town.

PYE, pi, Henry James, English poet-laureate: b. London, 10 July 1745; d. Pinner,

Hertfordshire, 13 Aug. 1813. He was educated at Oxford, and in 1784 entered Parliament from the county of Bucks, but played an unimportant part there. He was crowned laureate in 1790 and dutifully fulfilled the expectations of his office in producing his two odes a year. Other verse came from his pen, but nothing that rises above the dead level of commonplaceness. He was made one of the magistrates of Westminster in 1792. Pye was a voluminous writer, contributed to the literature of the stage and translated Aristotle's 'Poetics.' He seems, however, not to have set great store on his poetry himself, and observed that he had rather be thought a good Englishman than the best poet or the greatest scholar that ever wrote.

PYGMALION, pig-mă'li-ôn, (1) in Greek legend a son of Clix and grandson of Agenor, king of Cyprus. In the story told by Ovid (*Met.* x, 243) he conceived an aversion to women and devoted himself to art, but having made an ivory statue he became so enamored of it that he entreated Aphrodite to endow it with life. This was done: the statue became a beautiful woman whom Pygmalion married and by whom he had Paphos, founder of the city of that name in Cyprus. W. S. Gilbert's play, 'Pygmalion and Galatea,' is founded on this story. (2) Tyrian king and brother of Dido. He murdered Dido's husband Acerbas or Sichæus upon which Dido took her dead husband's treasures and sailed for the coast of Africa where she founded Carthage.

PYGMIES, the name given by the ancients to a race of dwarfish men reported as existing in various parts of the world. Homer (*Il.* iii, 6) fixes the habitat of the pygmies in the far south-land whither the cranes migrate at the approach of winter; after Homer the battles of the cranes and the pygmies are a favorite theme of poets, and are often pictured on vases. Ancient authors, whether travelers, historians, or miscellanists, like Herodotus, Ctesias or Pliny, describe the pygmæi as little men, the tallest of them not exceeding in height two *pygmæ* (Gr. *pygme*, a measure of length, the distance from the elbow to the knuckles — less than 14 inches). Herodotus locates his pygmæi in the heart of Africa in a region traversed by a great stream — probably the Niger — flowing from west to east and modern geographical research gives support to his story after it had long passed for fabulous. In recent times the actual existence of pygmies has been ascertained beyond any question, though when Paul B. Du Chaillu (q.v.) in 1861 published his 'Explorations and Adventures in Equatorial Africa' his description of the pygmy tribes discovered by him was scouted by scientific men as mere fiction. But when his report was confirmed in every essential particular by the missionary Father des-Avanchers (1869), by Schweinfurth (1871), by Stanley (1876) and others, scientific skepticism gave way, grudgingly to conviction of Du Chaillu's good faith. Many different tribes of pygmies are now recognized as existing in the interior of Africa, all possessing these characteristics: stature ranging from 33 inches to 4 feet 4 inches, as reported of the Wambutti by Stanley; Schlichter makes the average stature 4 feet 6 inches; complexion, from yellowish brown to reddish brown; usually heavy growth of hair on body and face — a curious item of

accordance with the report of Ctesias regarding the pygmæi of India, who had "beards and hair so long as to serve for vesture"; retreating forehead; prognathic jaw; fingers long, tapering, and feet strongly arched; in their villages the huts (8 feet long, 5 feet wide, 4 feet high) are clustered round the hut of the chief; their usual food is vegetable, but they eat almost anything; in hunting they show great intelligence; one tribe, the Wambutti, devise exceedingly ingenious nets, nooses and traps for securing game great and small.

Three types of pygmies are now recognized: (1) The African pygmies above described; (2) the Island pygmies of the Philippines, Andaman and the Tapirois, probably of African origin, but mixed breed; (3) the Asiatic pygmies, distinguished by wavy hair, found in the southern portion of the Malay Peninsula, in Celebes, and some Indian jungles. They are taller than the African pygmies and their heads are differently shaped, being dolichocephalic. Consult Wollaston, 'Pygmies and Papuans' (1912).

PYLADES, pi'la-déz, a legendary Greek hero, celebrated for the friendship which existed between him and Orestes. He assisted Orestes in murdering his mother Clytæmnestra, and eventually married Electra, the sister of his friend. See **ORESTES**.

PYLE, pil, Howard, American artist and author: b. Wilmington, Del., 5 March 1853; d. 1911. He combined literary and artistic talent, and in this double capacity began his career in New York City by contributing to various periodicals. Having achieved a reputation he returned to his native place where he resided after 1879. He was instructor at the Drexel Institute, Philadelphia, but his time was largely occupied with original productions for current periodicals. In art he especially affected scenes of colonial life and of mediæval folklore and was remarkably successful in conveying their spirit. Some of the finest achievements in color printing in the magazines of recent times have been from his drawings. Works of which he was both author and illustrator are 'The Merry Adventures of Robin Hood' (1883); 'Pepper and Salt, or Seasoning for Young Folks' (1885); 'Within the Capes' (1885); 'The Wonder Clock' (1887); 'The Rose of Paradise' (1887); 'Otto of the Silver Hand' (1888); 'A Modern Aladdin' (1891); 'Jack Ballister's Fortunes' (1894); 'Twilight Land' (1895); 'Semper Idem' (1903). He also wrote 'Rejected of Men' (1903), the story of the Christ in modern setting; 'The Story of Launcelot and his Companions' (1907); 'The Ruby of Kishmoor' (1908); 'The Story of the Grail' (1910).

PYLOS. See **NAVARINO**.

PYM, pim, John, English statesman: b. Brymore, Somersetshire, 1584; d. London, Dec. 1643. He was educated at Oxford, and in 1602 entered the Middle Temple, but was never called to the bar. He became member of Parliament for Calne in 1614, but from 1625 sat for Tavistock. He was prominent in the impeachment of the duke of Buckingham in 1616 and in 1639, with several others, held close correspondence with the commissioners sent to London by the Scottish Covenanters. When Parliament met again in 1640, Pym was one of

its most active and leading members, and in the Long Parliament, which met later that same year, he came most prominently to the front. Possessed of great eloquence, he made a vigorous and effective speech as soon as Parliament had opened, dwelling at length upon the grievances of the nation with respect to parliamentary privileges and civil and religious liberty. A few days after he followed up his speech by bringing a charge of high treason against the Earl of Strafford, prime minister of Charles I.; and in the impeachment which followed, resulting in the death of Strafford, he took the leading part. In 1641 a motion was carried by the opposition party to submit a remonstrance to the king, exposing the defects of his administration since ascending the throne, and the zeal of Pym in this matter led Charles into the imprudent measure of going to the Parliament in person to seize him and four other members. Clarendon relates that Charles I., feeling the necessity of gaining at any cost an enemy at once so implacable and so skilful, offered to Pym the post of chancellor of the exchequer. In November 1643, he was appointed lieutenant of the ordinance, but died the following December. He was buried with great pomp in Westminster Abbey. Consult Forster, 'Statesmen of the Commonwealth' (1841-44); 'The Arrest of the Five Members' (1860); and 'The Debates on the Grand Remonstrance' (1860); Smith, Goldwin, 'Three English Statesmen' (1867); Gardiner, S. R., 'The Great Civil War' (1893); Wade, 'John Pym' (1912).

PYNCHON, pin'chōn, John, American colonist: b. Springfield, Essex, England, 1621; d. Springfield, Mass., 17 Jan. 1703. He accompanied his father, William Pynchon (q.v.) to America in 1630, settling in the colony of Massachusetts. He succeeded his father in the government of Springfield in 1652, gained, by purchase and through his father, great tracts of land, and laid out the towns of Northampton, Hadley, Hatfield, Deerfield, Northfield and Westfield. He was eminently successful in gaining and keeping the friendship of the Indians, with whom he negotiated many treaties for the colonies. He was one of the commissioners to receive the surrender of New York from the Dutch in 1664. He was a deputy of the general court of Massachusetts in 1659-65, assisted under the first Massachusetts Royal Charter in 1665-86; and councillor from 1686 until his death.

PYNCHON, Thomas Ruggles, American Protestant Episcopal clergyman and physicist: b. New Haven, Conn., 14 Jan. 1823; d. 1904. Graduated from Trinity College in 1841, he was lecturer on chemistry there 1843-47; studied for the ministry, and was ordained priest in 1849. In 1849-55 he was in charge of parishes in Stockbridge and Lenox, Mass., and in 1854 accepted the chair of chemistry and natural science at Trinity College which he held until 1877 when he exchanged for the chair of moral philosophy. He was president of the college 1874-83. In 1874-78 he superintended the erection of the college buildings on the west side of the quadrangle and the transfer of the college to the new site. While in Europe 1855-56 he made a tour through southern France, Italy and Sicily, engaged in geological investigations, made a study of volcanic action, and ascended Mount Ætna

at night. In 1902 he became professor emeritus at Trinity. He is a member of the American Academy of Arts and Sciences, was one of the founders of the Meteorological Society, of which he is vice-president, and is connected with various other scientific societies both American and foreign. He has published 'Treatise on Chemical Physics' (1869); 'An Examination of Bishop Butler's Analogy' (1890).

PYNCHON, William, American colonist and religious writer: b. Springfield, Essex, England, 1590; d. Wraybury, England, 29 Oct. 1662. He was a man of education, one of the grantees of the Massachusetts charter and came to America with Gov. John Winthrop in 1630. He held various offices in the colony, from 1632 to 1634 acting as treasurer. He first settled at Roxbury as one of the founders of the village and organizers of the church, but withdrew in 1736 with the company led by Rev. Thomas Hooker and Rev. Samuel Stone southward into Connecticut. Pynchon with his family and a small party settled at the junction of the Agawam and Connecticut rivers and founded the town, now the city of Springfield. For several years this place was included in the Connecticut colony and Pynchon sat in its legislature, but in 1641, under Pynchon's influence, the Massachusetts court assumed jurisdiction. In 1650, during a visit to England, Pynchon published a book entitled 'The Meritorious Price of our Redemption.' In this the author took an anti-Calvinistic view of the atonement and so stirred up the colonists that the book was ordered to be burnt and the author cited to appear before the general court. His letter of explanation was deemed unsatisfactory and after being summoned a second time he left the colony in September 1652 and returned to England. He passed the remainder of his life at Wraybury, near Windsor. His earlier book was republished with a rejoinder to the Rev. J. Norton, as 'The Meritorious Price of Man's Redemption' (1655). He also wrote 'Jews Synagogue' (1652); 'How the first Sabbath was ordained' (1654); 'Covenant of Nature made with Adam' (1662). Consult Green, 'Springfield, 1636-1886: History of Town and City' (1888); Adams, 'Pynchon Family' (1898).

PYORRHEA ALVEOLARIS or **RIGG'S DISEASE**, a disease of the pericementum about the tooth, leading to receding gums, loose teeth, tooth abscesses and perhaps general body infection. It is of bacterial origin. Various forms of Staphylococci are found in the apical abscesses; micrococcus candidans is one of these. The disease when treated early can be controlled by competent dentists.

PYPIN, Alexander Nicolaevitch, Russian scholar, historian and author: b. at Saratov in 1833; d. Saint Petersburg, 9 Dec. 1904. Received his academic education at the University of Saint Petersburg, where he was appointed to a professorship in 1860, resigned two years later to enter the literary field. He contributed largely to the *Sovremennik* ("Contemporary"), 1865-67 and from then until his death to the *Vestrik Evropy* ("European Messenger"). His first work, a comparative study of Russian, Byzantine and Roman folk-lore, was published

in 1859, followed by a 'History of Slavonic Literatures' (1865), 'The Intellectual Movements in the First Half of the 19th Century' and a masterly biography in two volumes of Byelinski, the critic, in 1876. A four-volume work 'The History of Russian Ethnography,' was published in 1892-94 and the 'History of Russian Literature' in 1898-99. In 1897 he was appointed a member of The Academy of Sciences of Saint Petersburg, publishing for them the works of Catherine II.

PYRALIDÆ, a family of moths (q.v.).

PYRAMID, in architecture, a structure of masonry generally having a rectangular base and four triangular sides terminating in a point. According to Herodotus the Egyptians considered the pyramidal form as an emblem of human life; the broad base was significant of the beginning and its termination in a point of the end of our existence in the present state; for which reason they made use of this figure in their sepulchres. The most remarkable pyramids are those of Egypt and Nubia and those of Mexico. The Egyptian pyramids have for ages been a source of interest and curiosity and are regarded as forming one of the seven ancient wonders of the world. They are built mainly of a hard, rough-hewn limestone, but large blocks of granite are also used, especially on the outside. The four sides are so placed as to face the four cardinal points. Being intended both as monuments and as tombs, they contain one or more sepulchral chambers, quite small compared with the total mass. They appear to date from about 4750 to 3000 B.C. after which none were built. It is believed that most pyramids were begun over a sepulchral chamber excavated in the rock and that the work went on during the lifetime of the king for whom it was intended. A low narrow passage was kept open as the tiers of stone were added, in order that access might be obtained to the central chamber from without, and when the monarch died the work ceased and the last layers were then finished off and the passage closed up. The angles formed by the recession of each superior layer were filled up with small stones and beveled off, so as to give a smooth sloping surface to the sides. The stones used varied in diameter, two to four feet being common, but much larger, well-squared blocks were commonly used in facing. The mechanical skill requisite to quarry these and to raise them to such great heights and adjust them in their proper places continues a matter of universal astonishment. No indication of the mechanical contrivances used for this purpose has been left. The fact that an almost fabulous number of laborers were engaged in erecting these pyramids did not lessen the necessity for the employment of certain machines. The pyramids now standing, all in Middle Egypt, are divided into five groups, containing in all about 40 pyramids. The district in which the pyramids stand begins above Dashur and extends by Sakkarā and Memphis along the western margin of the valley of the Nile for about 60 or 70 miles, the last or Gizeh group being but a few miles above Cairo. The group of Gizeh, in the neighborhood of the ancient Memphis, is the most remarkable. It consists of nine pyramids and comprises the three most celebrated

monuments of the kind in existence, namely, the pyramid of Cheops, called Khufu or the Great Pyramid; that of Cephren and that of Mycerinus—the last much smaller than either of the others. According to Herodotus the Great Pyramid was built by Cheops. The tendency is to place the date earlier and earlier and one large volume has been devoted by V. P. McCarthy to demonstrate that it is at least 50,000 years old. It is estimated that it took 100,000 men working for 10 years to make a causeway 3,000 feet long, to facilitate the transportation of the stone from the Turah quarries, and the same number of men for 20 years more to complete the pyramid itself. Herodotus further describes the method of building by steps and raising the stones from layer to layer by machines and finally of facing the external portion from the top down. Diodorus calls the builder of this pyramid Chembes or Chabryes and by Manetho and Eratosthenes he is called Suphis. The latter name corresponds to Shufu, deciphered from the hieroglyphics upon some stones discovered by Colonel Vyse in his important investigations of this pyramid in 1835. The pyramid at present covers an area of more than 12 acres. The base is about 750 feet square, but was formerly about 768 feet. The perpendicular height, which before the disappearance of the apex was about 482 feet, is now 451 feet. The area at the top is about 12 yards square. The outer casing of small stones has been removed and the appearance the sides now present is that of a series of ascending steps. By these steps, which number 203, the ascent is made comparatively easy, though the lower ones are 4 feet 10 inches high. The content of solid masonry has been estimated at 82,111,000 cubic feet. The only entrance is on the north face, 49 feet above the base, though the masonry about it has been so much broken away that the débris reaches nearly up to it. A passage 3 feet 11 inches high and 3 feet 5½ inches wide conducts from the entrance down a slope at an angle of 26° 41', a distance of 320 feet 10 inches, to the original sepulchral chamber, commonly known as the subterranean apartment; it is carried, reduced in dimensions, beyond this a distance of 52 feet 9 inches into the rock, though for what purpose remains a matter of conjecture. The sepulchral chamber is 46 feet long by 27 feet wide and 11½ feet high. From the entrance passage another branches off and leads to several other passages and chambers. One of the latter, known as the queen's chamber, is situated about the centre of the pyramid, 67 feet above the base; it has a groined roof and measures 17 feet broad by 18 feet 9 inches long and 20 feet 3 inches high. The other, called the king's chamber, is reached by an offshoot from the queen's passage, 150 feet long. Its dimensions are 34 feet 3 inches long by 17 feet 1 inch wide and 19 feet 1 inch high. The chamber is lined with red granite highly polished, single stones reaching from the floor to the ceiling and the ceiling itself is formed of nine large slabs of polished granite extending from wall to wall. The only contents of the apartment are a sarcophagus of red granite, which, judging by its dimensions, must have been introduced when the building was proceeding. It is supposed to have contained a

THE GREAT PYRAMIDS, NEAR CAIRO

wooden coffin with the mummy of the king and that these long since disappeared when the pyramids were first opened and plundered. The second pyramid, built by Suphis II or Cephren, stands on a higher elevation than the Great Pyramid. Its original dimensions were 707 feet 9 inches square and 454 feet 3 inches high, but these now stand 690 feet 9 inches and 447 feet 6 inches, respectively, with an angle for its slope of $52^{\circ} 20'$. Part of the outer casing of the pyramid is still preserved. This pyramid has two entrances and the passages to which they respectively give access lead to the same sepulchral chamber, in which is deposited a granite sarcophagus. It was reached with great difficulty by Belzoni in 1818. Belzoni found in it a Cufic inscription recording the visit of the Caliph Alaziz Othman Ben-Yusuf and the opening by him of the pyramid in 1196 A.D. The only remains met with were those of a bull. The third pyramid, built by Menkaré or Men-kau-Ra or Mycerinus, is only 354 feet 6 inches square and 203 feet high. It also was explored by Colonel Vyse in 1837. He discovered several chambers, one of which contained a sarcophagus and a mummy case bearing the name of Men-kau-Ra and also a body, supposed to be that of an Arab. The two latter are now in the British Museum, but unfortunately the sarcophagus was lost by the sinking of the vessel in which it was being transported to this country. This pyramid is the best constructed of the three; it was originally cased half-way up with black granite. The six smaller pyramids which complete the Gizeh group are supposed to form the tombs of some of the relatives of the kings who constructed the larger ones and are of much inferior interest to the three above mentioned. Of the other groups of pyramids that at Abusir contains five; another at Sakkará contains 11, one with a doorway inlaid with porcelain tiles and having a royal name, and a third group at Dashur contains five. Other pyramids are at Meydun and Illahun and there are two at Biahmu. The pyramids of Nubia are very numerous; a single group north of Gebel Barkal comprises no fewer than 120. In Babylonia the Birs Nimrud or Tower of Belus was a kind of a step-shaped pyramid, built of bricks of different colors. It was erected by Nebuchadnezzar and dedicated to the planets. Its height was 235 feet and its circumference 2,286 feet. The Mujellibe in Babylon, of which the ruins are still to be seen, was another pyramidal structure of the same monarch. Ruins of pyramids are to be found at Benares in India and in other parts of the East. Certain monuments of the ancient inhabitants, found in Mexico, are also called pyramids. (See *MEXICAN ARCHÆOLOGY*). Consult Lepsius, 'Ueber den Bauder Pyramiden'; Vyse, 'Operations carried on at Gizeh in 1837'; Petrie, 'The Pyramids and Temples of Gizeh' (1884); Maspero, 'L'Archéologie Egyptienne' (1887); McCarthy, 'The Great Pyramid Jeezeh' (1900); Barber, 'Mechanical Triumphs of the Ancient Egyptians' (1900); Baedeker, 'Egypten' (1814 ed.).

PYRAMID, in geometry, a polyhedron with a polygon as base and triangular sides meeting in a common point called the vertex. A regular pyramid has a regular polygon for

base, while the perpendicular from the vertex to the base passes through its centre. The volume of a pyramid is one-third the altitude multiplied by the area of the base. The perpendicular distance between the base and the vertex is the altitude. The slant height is the height of any of the triangular sides of a regular pyramid. The total area of the sides of a regular pyramid is one-half the perimeter of the base multiplied by the slant height. Pyramids are named according to the nature of their bases; they may be triangular, quadrangular, etc., according as their bases are triangles, quadrilaterals, pentagons, etc. The base and lateral triangles are called faces; the lines in which the faces meet are called edges.

PYRAMID PEAK, a name given to two mountain peaks in California and two in Colorado.

PYRAMUS (pîr'á-mus) AND **THISBE**, thîz'bê, a pair of unfortunate lovers whom classical legend represents as living in Babylon. Their parents were enemies and would not sanction the marriage of the lovers, but the two contrived to converse with each other in secret through an opening in the walls of their adjoining houses. They finally determined upon a meeting at the tomb of Ninus. Thisbe was first to arrive, and meeting a lioness who had just killed an ox, she ran away, dropping her mantle in her flight. This the lioness soiled with blood, and Pyramus arriving shortly after and finding the blood-stained garment of his betrothed, imagined her to have been killed and ended his life beneath a mulberry tree, the fruit of which (according to the legend) has since been of a blood-red hue. Thisbe returning finds the body of her lover, whereupon she then kills herself in despair. The legend is embodied in Ovid's 'Metamorphoses' and is caricatured in the farcical interlude in Shakespeare's 'Midsummer Night's Dream.'

PYRRARGYRITE, pî-râr'jî-rîr ("dark ruby silver"), a rhombohedral mineral, usually of high-metallic-adamantine lustre, color black by reflected light, rich ruby-red by transmitted light, hardness 2.5, specific gravity 5.85. It is a silver sulph-antimonite, and may contain 60 per cent of silver. It occurs in magnificent specimens in Germany, Mexico, Chile and Bolivia, and is an important silver ore in these countries and in the mining regions of the western United States.

PYRENE, a hydrocarbon product of coal-tar distillation ($C_{10}H_{16}$). Also the name of a commercial fluid for fire extinguishing.

PYRENEES, pîr'ê-nêz, a lofty mountain chain forming the boundary between France and Spain. Its length, from Cape Creux, north of the Gulf of Rosas, to the Point of Figuiér, near Fuenterrabia, is nearly 270 miles; and the area of its slopes is about 21,000 square miles. The chain is continued across the north of Spain by the Cantabrian Mountains. The direction of the chain is east-southeast, to west-northwest. It does not, however, lie in the same straight line, but rather consists of two lines, which form parallel ridges about 20 miles distant from each other, except near the centre, where they become united by means of a remarkable rectangular elbow, in which some of the loftiest summits are found. Both on the north and south sides numerous branches are

thrown off, generally at right angles to the principal axis, and subside rapidly as they recede from it, forming various transverse but very few longitudinal valleys. The chain rises both from the east and west toward the centre; and, in accordance with a general rule which holds in regard to the European chains, which lie in the direction of the equator, the descent on the south side is much more abrupt than on the north. Owing to this, the south has much fewer lakes than the north slope, but far surpasses it in the boldness and grandeur of its scenery. As already observed, the loftiest summits of the chain are near its centre. Its culminating point, Maladetta, situated there, has the height of 11,168 feet, and a great number of peaks in the same locality exceed 8,500 feet. To the east of the centre the chain lowers so rapidly that its average height soon becomes little more than 2,000 feet. To the west the height diminishes much more gradually, and many peaks have heights varying from 5,000 to 7,000 feet, and even 8,000 feet. The principal passes in the Pyrenees formed by the meeting of valleys from opposite sides of the axis, take in the east part of the chain the name of Cols, and toward the centre that of Ports. No fewer than 75 are counted, of which 28 may be crossed on horseback and seven in wheeled carriages. The most frequented are those of Pertus and La Perche in the east and Saint Jean Pied de Port in the west. The nucleus of the chain is evidently granite, which, with the primitive schists which overlie it, constitutes the loftiest summits, with the exception of Mount Perdu (10,994 feet), Marboré (10,673 feet), and some huge adjacent masses which are formed of mountain limestone. The granite, however, seldom forms continuous ridges along the principal axis, but rather appears in a number of remarkable protuberances situated to the north of it. Above the micaceous schist and primitive limestone, which occur in connection with it, lie largely-developed strata of argillaceous schist and transition limestone, forming two great belts parallel to the primitive chain, one on the north and the other on the south side. Above these secondary rocks appear, of which by far the most common is the mountain limestone, which occupies the greater part of the south slope, but on the north side attains little elevation, being there almost entirely confined to the lower heights at the bottom of the principal chain. Above the mountain limestone the principal rocks are Jura limestone and trap. The number of thermal springs existing in the Pyrenees seems to indicate the presence of volcanic agents, but basalt and other rocks of igneous origin are very rare. The minerals of the chain include iron, copper, lead, zinc, manganese, antimony and cobalt. There is no mine either of silver or gold, but particles of the latter are found in department Ariège, and in the streams of several other districts. The only mineral which has hitherto been worked to much advantage is iron. Mineral springs, both cold and thermal, are numerous, and much frequented by visitors. The limit of vegetation on the Pyrenees is about 600 feet higher than on the Alps. The rhododendrons, which in the latter are not found higher than 5,000 feet, are here found at 5,500 feet and alpine plants are found on the loftiest summits bordering on the region of perpetual snow. In the Pyrenees this

is found only on the north slope, where it does not, as in the Alps, form a snowy zone, the lower limit of which looks as if traced out by an almost horizontal straight line; but on the contrary, forms large isolated masses, the base of which is often concealed by the mountains in front of them. This makes it difficult to fix the snow-line with precision, but according to the most accurate estimate it is 9,190 feet, or nearly that of Mount Canigou. Glaciers are not numerous in the Pyrenees, and hence the torrents and rivers which rise in the chain are fed chiefly by springs. Those on the south side flow toward the Ebro and are carried by it to the Mediterranean; those on the north side flow partly to the Mediterranean and partly to the Atlantic, the water-shed between the two seas being carried northward by a branch which ultimately links with the Cevennes. The largest river of the chain, and the only one of importance which preserves its name throughout its whole course, is the Garonne. In respect to average height and mass the Pyrenees are unquestionably the second mountain chain of Europe, but its culminating point, Maladetta, has only the third place, being indeed lower than Mulhacen in the Sierra Nevada. Contrary to the general rule, that the loftiest summits of mountain chains are found in the line of the principal axis, Maladetta, Posets (11,047 feet) and Mont Perdu, the three culminating points of the Pyrenees, are situated on the south slope. Basses-Pyrenees, Hautes-Pyrenees and Pyrenees-Orientales are departments in the south of France (q.v.). See also PERPIGNAN, CAPITAL OF P. ORIENTALES.

Consult Taine, 'Voyage aux Pyrénées,' especially the 4th ed. (1873) with illustrations by Doré; Schrader, 'Les Pyrénées,' in the 'Annuaire du Club Alpin français' (1885); De Margerie and Schrader, 'Aperçu de la Structure géologique des Pyrénées' (1891), and 'Aperçu de la Forme et Relief des Pyrénées' (1892); Camena d'Almeida, 'Les Pyrénées: Développement de la Connaissance géographique de la Chaîne' (1893); Trutat, 'Les Pyrénées' (1894); Buhanus, 'Flora Pyrenæa' (1897-1902); Spender, 'Through the High Pyrenees' (1898); Roussel, 'Tableau Stratigraphique des Pyrénées' (1904); Cook, 'Handbook to Health Resorts on the Pyrenees' (1910); Freeston, 'Passes of the Pyrenees' (1912).

PYRENEES, Peace of the, in European history the name given a treaty concluded between France and Spain by Cardinal Mazarin and De Haro, on the Ile des Faisans, in the river Bidassoa, 7 Nov. 1659, terminating a war which had lasted for 24 years. By this treaty Spain ceded to France Roussillon, with the fortress of Perpignan, etc., so that the Pyrenees have since formed the boundary of the two kingdoms; and in the Netherlands, Artois and part of Flanders, Hainault and Luxemburg, with a number of fortified towns.

PYRETHRUM, a group of composite plants formerly considered a genus, but now ranking as a section of the genus *Chrysanthemum*. In garden literature the name is generally restricted to *Pyrethrum roseum*, several hundred varieties of which are widely popular in European gardens. Under the name *Chrysanthemum coccineum* it is extensively cultivated in southern France, California and western Asia

for its flowers, which are dried and ground as the material of insect powder. Another species (*C. cinerariaefolium*) is also cultivated for this purpose. The well-known bedding-plant "golden feather" is a variety *C. Prænitens*, but is widely known as *Pyrethrum aureum* among horticulturists. The plants are easy to grow in any good garden soil, if deeply dug and highly enriched. Since the seed is often disappointing in its results, the plants are best propagated from choice varieties by division in the spring. The golden-feather pyrethrum is often propagated by cuttings made during the winter from stock plants.

PYRGOS, pir'gōs, Greece, capital city of the monarchy of Elis and Achia, 13 miles west of Olympia, on the west coast of the Morea, near the mouth of the Ruphia (Alpheus), on the railroad from Piræus to Olympia, and with branch connections with its harbor, Katakolon. The surrounding country is a fertile plain, growing currants, oranges and grapes. The commune has a population of about 27,000; the town, 13,690. Three other small towns in Greece bear the same name.

PYRHELIOMETER, an instrument for measuring the intensity of the heat of the sun's rays. Pouillet's instrument was the first called by this name. It is a form of radiometer, operated on an actinic principle. A vessel containing water was used to float a black box with thermometer bulb sunk in the fluid. The difference between the heat shown under exposure and when the sun's rays were cut off was the basis of measurement. Angstrom's compensating pyrheliometer employs the thermo-electric principle. Two similar metallic strips, as of platinum, are blackened, and one exposed to sunlight while the other is in shade. The difference in electrical resistance of the exposed and the shaded strips is determined by switching on a current, and this permits a determination of the relative temperatures. An improved form used by the United States Weather Bureau was designed by C. F. Marvin. This employs twin strips of blackened silver, which are alternately exposed to the sunlight for one minute, by the use of a timed shutter. An electric resistance thermometer measures the heat through the difference in electric resistance. Consult Abbot, 'Smithsonian Institution Miscellaneous Collections' (Vol. XVI, 1915).

PYRIDINE (C_5H_5N), an organic base, originally found in bone oil, as a decomposition product, now known to be obtainable from bituminous coal, petroleum, etc., and also produced synthetically by heating amyl nitrate with phosphoric oxide. The most common source is the lighter oils of coal-tar distillation. It is obtained pure by transformation into one of its salts, followed by repeated crystallizations. When pure it is a colorless liquid, boiling at $114.5^\circ C.$ ($238^\circ F.$). It is the base of many valued derivatives. The more important acids obtained are picolinic a., nicotinic a., quinolinic a., cinchomeronic a., carbochincomeric a., and berberonic a. Trigonelline and piperidine are two of the most important commercial derivatives.

PYRITE, or **IRON PYRITES**, the commonest metallic mineral, like copper pyrites, is often called "fool's gold," owing to its resem-

blance to gold. It may readily be distinguished by its much greater hardness, 6 to 6.5, brittleness, pale brass-yellow color, greenish-black streak, and specific gravity, 4.95 to 5.10. It crystallizes in isometric crystals often of great beauty, but is usually found massive as a vein material or in beds of great extent. It is an iron disulphide, FeS_2 . Its high sulphur percentage, 53.4, and the ease with which it may be burned, leads to its enormous consumption in the manufacture of sulphuric acid. Owing to its ready oxidation, with the formation of sulphuric or sulphurous acids, it is an active agent in the disintegration of those rocks through which it is disseminated. It frequently contains gold and to some extent other valuable metals. It is not an economic ore of iron, on account of the difficulty of removing the sulphur content. Its most important commercial occurrence is at Rio Tinto, Spain. It is also extensively mined near Rowe, Mass., in Virginia, the Carolinas, Georgia, Colorado and in many other regions. The finest crystals come from Elba, Cornwall in England, Peru, Chester County, Pa., and Central City, Colo. See MINERAL PRODUCTION OF THE UNITED STATES.

PYRITES, either of the various metallic sulphides, of which the most important is iron pyrites (see PYRITE). Copper pyrites (see CHALCOPYRITE) is an important ore of copper. Arsenical pyrites (see ARSENOPYRITE) furnishes much of the arsenic of commerce; magnetic pyrites (see PYRRHOTITE) is often an important nickel ore.

PYRMONT, pēr'mōnt, Germany, a celebrated watering-place of Prussia, in the principality of Waldeck and Pyrmont, capital of the district; in a beautiful valley at the foot of a range of finely wooded hills, on the left bank of the Emmer, 34 miles south-southwest of Hanover. It contains a palace, in which the Prince of Waldeck and Pyrmont resides during the watering season; and it was much frequented before the war by the aristocracy of Germany; from 10,000 to 20,000 visitors being annually recorded. One of the curiosities of the place is the Dinsthölle or gas grotto, which emits vapors similar in nature and effect to those of the Grotto del Cane in Italy. Pop. about 1,700.

PYROCLASTIC, fragmental volcanic material resulting from violent explosive eruptions. The finest particles are known as volcanic ash, or simply as ash. This is not ash in the sense that it is a product of combustion, but is finely divided rock material that has been blown into bits. Volcanic ash has been an important factor in the destruction wrought by volcanic eruptions. It may be wind drifted for long distances. Beds of this ash in the Great Plains of Kansas and Nebraska were probably drifted from the Rocky Mountain region. Volcanic ash is sometimes employed as a base for scouring soaps and polishing powders. Lapilli is much the same as ash, but slightly coarser, averaging about the size of peas. Bombs are larger masses of lava hurled from the craters, often in a partly molten state, in which case they are rendered rounded by the whirling motion they assume in the air.

PYROGALLIC ACID, **PYROGALLOL**, **TRI-OXY-BENZENE**, $C_6H_3(OH)_3$, (1:2:3), is produced by the action of heat on gallic acid, carbon dioxide being eliminated in the process.

Fine colorless needles or plates, readily soluble in water, less so in alcohol or ether, melting point 132° C. Valuable because of its great affinity for oxygen, its alkaline solution is used to absorb oxygen in gas analysis. It is used extensively as a photographic developer, but has the disagreeable power of darkening the skin. It forms a number of derivatives, some being valuable in the treatment of skin diseases.

PYROGRAPHY, from *πυρ*, fire and *γραφειν*, to write, literally to write by fire. A method of making impressions on wood, leather, etc., by means of heated metal tools or burnt sticks. The art was early practised by the Egyptians who used crude iron bars that had been previously heated in fire. A modern form of pyrographic apparatus consists of a tube about six inches in length and about half an inch in diameter provided at its lower extremity with a screw-cap and a small support. At the other end there is a rod to which the drawing point is affixed. For the formation of the combustible gas and heating of the rod sulphuric ether is usually employed. The gas when generated is forced to the metallic point by means of air pressure, and after the flame has been regulated a person may work for two consecutive hours at an expense of about one-half cent per hour. The vapors disengage themselves constantly and feed the small flame which is barely perceptible. The heat is always uniform, and even on leather a sure and sharp execution of the design is possible. Electrically heated points are also used. The effects produced by the pyrograph are equal in many respects to the fine crayon drawings, and when colored and varnished present a very pleasing effect. The finest and most delicate lines can be drawn and there is no danger of burning holes in the material. The right hand being engaged in the execution of the piece to be ornamented leaves the left free to turn the object in any desired position while the work is in progress.

Pyrography is taught in many trade schools, and is used mainly for ornamenting leather and wood. Consult Bolas and Leland, 'Pyrography and Wood Roasting' (1899); Maude, 'Pyrography' (1891).

PYROLIGNEOUS ACID, an impure, dilute form of acetic acid obtained by the dry distillation of wood. The foliaceous trees, especially the beech, or the oak and birch, which latter having been deprived of their bark are better adapted for its manufacture than the conifers. The dry distillation of wood is accomplished in iron airtight retorts, of which there are many styles; and in accordance with the temperatures employed varying products, which are partly gaseous and partly liquid, are formed. The gases are consumed and the liquid component separates into two layers of which one is aqueous and dark brown, containing the wood vinegar, while the other is oily, almost black, containing wood tar. During distillation the first distillates, which contain very little acid, pass over at $175\text{--}235^{\circ}$ F. ($79\text{--}113^{\circ}$ C.) while at 288° F. (142° C.) the lighter oils pass. As soon as the water shows a sufficient content of acid the temperature is raised to 315° F. (157° C.). Above that temperature the heavier oils distil over. The quantities received vary, as has been said, according to the temperature employed: in general about 35 per cent of pyro-

lignous acid; 20 per cent of wood tar and 33 per cent of charcoal are the products.

Pyroligneous acid, as it is received from the still, is a reddish brown fluid having a rather disagreeable, sour, smoky, empyreumatic odor and taste. It is a very complex product, containing besides acetic acid, all the homologues of acetic acid from formic to caproic acid; methyl alcohol, acetone, metacetone, aldehyde, etc.

Commercial acetic acid is prepared chiefly from pyroligneous acid purified by distillation and strengthened by rectification, the acetic acid obtained by the oxidation of ethyl alcohol being of limited concentration and used principally for table use, and preserving food articles. The crude pyroligneous acid is used for the preservation of wood and ropes, for embalming, in veterinary surgery for many diseases, and in some of the arts, as in calico printing.

PYROLUSITE, the most important ore of manganese. It is a black or gray mineral of brilliant metallic lustre. It is distinguished from manganite and polianite, which it much resembles, by being so soft (hardness 2 to 2.5) as readily to soil the fingers. Its black streak further separates it from manganite. While its crystallization is orthorhombic, it is usually massive or radiating-columnar. Chemically it is manganese dioxide, MnO_2 . It has long been used in the manufacture of chlorine and oxygen, and in decolorizing glass; its present most important use is in the preparation of manganese steel. It occurs abundantly in Thuringia and elsewhere in central Europe, also in Nova Scotia and Brazil. In the United States it is mined in Virginia, Georgia and Arkansas.

PYROMANIA, incendiary monomania, a form of insanity characterized by an irresistible desire to destroy by fire. In most forms of mental disease self-control is lost, but in pyromania the loss of the power of inhibition is the chief symptom; hence the affection is sometimes spoken of as a form of inhibitory insanity, a psycho-neurosis caused by decreased psychological tension. The desire to commit arson manifests itself during certain periods between which the pyromaniac is sub-lucid and may even attend to his affairs, although he exhibits some nervousness or hysteria. Usually a period of depression precedes an attack. See **INSANITY**.

PYROMETER, an instrument for measuring temperatures higher than the boiling-point of mercury (350° C.). Regnault and other careful experimenters employed the expansion of air and vapors in measuring high temperatures. These pyrometers can only be used in a laboratory; for use in a manufactory less accurate methods of measurement have to be employed. In Wedgwood's pyrometer (1782) it was assumed that dry clay, when exposed to heat, contracted regularly, and the instrument was constructed on this principle; but it is now known to be untrustworthy. An instrument in which the expansion of a metal bar (generally of platinum) was magnified by means of levers has often been employed to measure the temperature of a furnace. Morveau, Brongniart and Daniell invented instruments on this principle. The thermo-electric law of Tait may be used to calculate the temperature to which a junction of copper and iron has been sub-

jected, the electric current produced being measured by a galvanometer. In this way high temperatures have been measured with considerable accuracy. By Siemens' method temperatures are measured by observing the increased electric resistance of a platinum wire when heated, two coils of the same kind of wire being prepared so as to have equal resistances at the same temperature, their ends connected by rather long thick copper wires and the current from a constant battery passing through them measured by means of a galvanometer. One of the coils is kept at a known temperature, the other has the temperature which it is desired to measure. The law discovered by Siemens—

$$R = \alpha \sqrt{T + \beta T + \gamma}$$

where R is the resistance at the absolute temperature T , and where α , β and γ are certain numbers, enables the temperature to be calculated. Pouillet determined the following temperatures by means of an air-thermometer. They correspond to the stages of incandescence of a metal bar.

Incipient red-heat.....	525° C.
Dull red.....	700°
Cherry red.....	900°
Dark orange.....	1100°
White.....	1300°
Deadling white.....	1500°

In potteries cones and rings of clay are employed to measure temperatures. The cones are made to soften at a known heat and the rings indicate rising temperature by expansion. For optical purposes pyrometers are made to indicate by showing metallic colors that are compared with a standard. A simple form of pyrometer measures radiation and operates a pointer by a bimetallic spring. The thermoelectric principle is now employed in recording pyrometers that may be located at a distance from the furnace. See THERMOMETRY.

PYROMORPHITE, a mineral occurring in hexagonal crystals, often cavernous and barrel-shaped, or in curious, nearly parallel groups tapering to a point. It is a lead phosphate and chloride and occasionally occurs in sufficient quantities to be an important lead ore. Its hardness is 3.5 to 4, specific gravity 6.5 to 7.1, color commonly green, yellow or brown, lustre resinous. Its most notable occurrences are Ems, Germany; Cumberland, England; Broken Hill, New South Wales, and in the United States formerly at Phoenixville, Pa.

PYROPE, or **BOHEMIAN GARNET**, a fine dark-red magnesium-aluminum garnet, often called "precious garnet" because of its extensive use as a gem. It is slightly yellower than the true ruby. Peridotite, or serpentine derived from it, is the usual matrix of pyrope in Bohemia and in Kimberly, South Africa, but more commonly it occurs as rounded pebbles loose in the sands, as in the ant-hills of the Navajo Reservation in Arizona. It is also found in Colorado, New Mexico and Kentucky, in Scotland and Brazil. It is often incorrectly called "ruby." Consult Kunz, 'Bohemian Garnets,' trans. 'Amer. Inst. Mining Engineers' (1893). See CARRUNCLE; GEMS.

PYROPHONE, a musical instrument, in which the various notes are produced by the burning of hydrogen gas within glass tubes of various sizes and lengths. It is also called a

flame-organ and was invented about 1875 by a Frenchman called Kastner.

PYROPHYLLITE, or **PENCIL STONE**, a mineral of soapy feel, the compact form of which is extensively mined in North Carolina as soapstone. Its uses are the same as those of the related mineral talc (q.v.). Some of the algamatolite used by the Chinese for carving into pagodas and images is pyrophyllite. The mineral is usually found in coarse lamellar radiations, occurring thus in fine specimens in Switzerland, Georgia, North Carolina and California. Chemically, it is a hydrous aluminum silicate.

PYROSCOPE, an instrument for measuring the intensity of heat radiating from a hot body, or the frigorific influence of a cold body. It is commonly constructed on the principle of a differential thermometer. Compare PYROMETER.

PYROSIS, or **WATERBRASH**, a burning sensation in the epigastrium, usually followed by an acrid watery discharge into the mouth. It is a symptom of indigestion, and when felt simply as heat, without rising, is misnamed heartburn. It arises from an excess of hydrochloric acid in the stomach. A reduction of the acid and avoidance of starchy foods are the recognized forms of treatment. See DYSPEPSIA.

PYROTECHNICS, the art or business of manufacturing or displaying fireworks. The common ingredients are nitre, sulphur and charcoal, together with filings of iron, steel, copper, zinc and resin, camphor, lycopodium, etc. Gunpowder is used either in grain, half crushed, or finely ground, according to the desired effect. The proportions of the materials differ very much according to the speed of combustion and the color of flame desired, and the utmost care and precaution are necessary in the manufacture. Lampblack produces a very red color with gunpowder, and a pink with nitre in excess. Yellow sand is introduced to secure golden showers. Verdigris imparts a pale green, sulphate of copper and sal-ammoniac a palm-tree green. Camphor produces a very white flame, with aromatic perfumes, which mask the bad smell of the other ingredients; benzoine and storax are also used on account of their agreeable odor. Lycopodium, which is often used in the manufacture of stage-lightning, burns with a rose color and a magnificent flame. The familiar types of fireworks are: (1) set pieces, that give off showers of colored sparks or flame, sometimes elaborately arranged to form pictures of fire in the air; (2) pinwheels, that discharge products of combustion from radiant spokes, and so rotate a burning wheel supported by a central pin; (3) rockets, that are held by a light stick, discharged rearward, the reaction carrying them off in the air (a description of sky-rockets will be found under PROJECTILES); (4) Roman candles, that discharge flaming colored balls or stars or bombs; (5) firecrackers, small paper cylinders having a charge of gunpowder ignited by a fuse. Nearly all of these are confined in cylindrical paste-board cases, with a fuse of paper cord enclosing a fine train of quick-burning powder. Great ingenuity has been expended in obtaining beautiful effects in pyrotechny. The indiscreet use of

fireworks by boys and incompetent persons resulted in so many accidents, especially on the fourth of July, in the United States, that "fireless fourths" have resulted in most large cities, and the tendency is to confine exhibitions of pyrotechnics to displays under the management of trained experts, the combustibles being so placed that they are largely shut off from any crowd of spectators.

PYROXENE, a mineral formed commonly in crystalline limestone or dolomite, in serpentine and in rocks of volcanic origin. Less abundant in granite rocks and metamorphic schists. Crystalline form, rhombic, monoclinic or triclinic. Brittle. Hardness, 5 to 7. Specific gravity, 2.8 to 3.7. Of a vitreous or resinous lustre. Color is usually some dull shade of green, but may vary to nearly colorless or to brownish black. Composition an isomorphous mixture metasilicates, $RSiO_3$, where R is Ca, Mg, Fe, sometimes Mn or Zn, rarely the alkali metals. Important varieties of pyroxene are diopside, hedenbergite, schferite, augite. Pyroxene is one of the most important of the rock-forming minerals being an essential constituent of basalt, diabase trachyte, syenite, gabbro, pyroxenite and many other rocks. It is thus widely distributed in all parts of the world. Especially fine crystals occur in the Piedmont, in Sweden, northern New York and southern Canada and in New Jersey.

PYROXYLIN. See GUN-COTTON.

PYRRHIC (pîr ik) **DANCE**, a famous war-dance of antiquity. It was danced to the sound of the flute, and its time was very quick and light. It was introduced into the Roman public games by Julius Cæsar, and was danced by male and female dancers, having much of a dramatic character.

PYRRHIC VICTORY, a victory so dearly bought that it is almost a defeat, so called from the defeat of the Romans at Asculum 279 B.C. by Pyrrhus. See PYRRHUS.

PYRRHO, pîr'ô, Greek philosopher: b. Elis, about 365 B.C.; d. about 270 B.C. He was a pupil of the Democritean philosopher Anaxarchus of Abdera, whom he accompanied to India in the train of Alexander the Great. During this journey he became acquainted with the doctrines of the Brahmins, Magi and other eastern philosophers. His doubts concerning positive knowledge were strengthened as he proceeded in his studies, until at length he came to hold all knowledge uncertain, and considered virtue alone as valuable. In all disputes his answer to his opponents was, "What you say may, or may not, be true; I cannot decide," and he taught in his school that truth could not be attained, and that we must be content to suspend our judgment on all subjects. He spent much of his life in solitude, and by abstaining from all decided opinions concerning moral and physical phenomena, endeavored to attain a state of tranquillity unaffected by fear, joy or sorrow. His countrymen, the Abderites, made him high-priest, and exempted all philosophers from the payment of taxes. The Athenians erected a statue in honor of him, and his countrymen raised a monument to his memory. His skepticism is easily accounted for. His master, Democritus, held that except the immediate elements of bodies (atoms) nothing was real, and that all perception was

subjective. He was confirmed in these views by the doctrines of Socrates, to whom, in his character, he bore great resemblance, and his skepticism is allied to the irony of that philosopher. Led by his temperament and manner of life to esteem uninterrupted tranquillity the great object of all philosophy, believing that nothing tended so much to destroy this quiet as the interminable disputes of the schools of the dogmatists, and that uncertainty was increased by their contentions, he determined to seek in some other way the peace which he despaired of finding in dogmatical philosophy. A disposition to doubt is often called, from this philosopher, Pyrrhonism. Consult Überweg-Prachter, 'Grundriss der geschichte der Philosophie' (Berlin 1914).

PYRRHONISTS. See RELIGIOUS SECTS.

PYRRHOTITE, pîr'o-tit, or **MAGNETIC PYRITES**, a metallic mineral, in composition an iron sulphide, probably $Fe_{10}S_{11}$, differing from common iron pyrites, FeS_2 , in percentage composition, in being attracted by the magnet, in its bronze color, inferior hardness (3.5 to 4.5), and specific gravity (4.6). It rarely crystallizes in hexagonal, tabular crystals; usually it occurs massive. Though pyrrhotite contains over 60 per cent of iron and nearly 40 per cent of sulphur, it is only very recently that it has been regarded as of any value for these ingredients. Its commercial value was due entirely to the occasional presence as an impurity of varying percentages of nickel. Formerly the deposits of nickeliferous pyrrhotite at the Gap Mine, Pennsylvania, were extensively worked, but the far richer and more extensive deposits at Sudbury, Ontario, are now the chief sources of nickel. Enormous beds of copper-bearing pyrrhotite, nearly free from nickel, are successfully worked in Vermont. Choice crystallized specimens are found in Austria, Brazil and at Tilly Foster, N. Y.

PYRRHUS, pîr'ûs, Greek military leader, king of Epirus: b. about 318 B.C.; d. Argos, 27 B.C. He was the son of Æacides, who traced his descent from Pyrrhus, son of Achilles. He spent an eventful youth, regained the throne from which his father had been deposed, and was himself expelled several years later. He became the friend of Demetrius Poliorcetes, whom he accompanied on the fatal campaign closed by the battle of Ipsus (301 B.C.), then proceeded to Egypt as hostage for Demetrius, and there married Antigone, daughter of Queen Berenice. With the aid of Ptolemy Soter he recovered his kingdom (296), agreeing to share the sovereignty with Neoptolemus, who had been king since his expulsion, but soon after put his colleague to death, and succeeded by courage, affability and generosity in gaining the admiration of his soldiers and people. He temporarily conquered Macedonia, and in 280 went to southern Italy at the head of a large army to assist the Tarantines against the Romans. Near Heraclea, on the Siris, the consul M. Valerius Lævinus was defeated by Pyrrhus, whose elephants played an important part in the conflict, his loss being so great that he is reported as saying "Another such victory and I must return to Epirus alone." After having approached within 24 miles of Rome he returned to Tarentum. In 279 he again defeated

the Romans, but was glad to accept the offered truce, and passed with his army into Sicily, where he assisted the Greeks against the Carthaginians. At first he met with brilliant success; but his attack upon Lilybæum failed. The war ended in the following year with the total defeat of Pyrrhus by the Romans under Curius Dentatus, near Beneventum. On this occasion the famous elephants of Pyrrhus rushed back upon his own army and contributed to his loss. He reached Epirus with a small remnant of his once splendid army. Nothing daunted, he again invaded Macedonia, and became its king a second time. He afterward turned his arms against Sparta, but was driven from before the walls of that city. In a night attack made upon Argos he was stunned by a tile thrown by a woman from a house-top, and being recognized by the enemy's soldiers was slain.

PYRUS, or **PIRUS**, a genus of fruit-bearing shrubs and trees of the rose family. There are about 40 species, natives of the southern hemisphere and especially of the cool temperate parts. They have usually simple leaves, clusters of showy white, pinkish or bluish flowers after the leaves appear, and fleshy fruits (pomes). Horticulturally this is one of the most important of plant genera, since it includes the apple, pear, quince and medlar (qq.v.). The last two, however, are often separated into distinct genera. Some of the species, as crab-apples, are cultivated for ornament.

PYTHAGORAS, pi-thăg'ô-ras, Greek philosopher: b. Samos, about 582 a.c.; d. about 507. His Father, Mnesarchos, was a merchant (probably of Tyre or some other Phœnician city) who traded with Samos, where he received the rights of citizenship, and settled with his family. The biography of Pythagoras is mingled with many fables. He received his first instruction from Creophilus in his native city. He then went to the island of Scyros, and was a scholar of Pherecydes till the death of the latter; others make him also a scholar of Thales and Anaximander. Iamblichus says that Pythagoras, during his journey to Egypt, spent some time in Phœnicia in intercourse with the successors of Moschus, and other priests of the country, by whom he was initiated into their mysteries, and that he traveled through various parts of Syria in order to become acquainted with the most important religious usages and doctrines. He is said to have been recommended by Polycrates, king of Samos, to the Egyptian king Amasis. In Egypt he became acquainted with the whole range of Egyptian learning. He remained in Memphis and Thebes 22 years, and was in Egypt when that country was conquered by Cambyzes. Like many others of the sages in that kingdom, he was carried captive to Babylon, where he conversed with the Persian and Chaldean Magi; and traveled as far as India, and visited the Gymnosophists. After his return he opened a school at Samos, in which he taught his doctrines in a symbolic form, in imitation of the Egyptians. He also visited Crete, where the priests of Cybele took him to the caverns of Ida, in which Jupiter had been cradled. Here he met Epimenides, whom he initiated into the sacred mysteries of the Greeks. From Crete he went to Sparta and Elis, and from thence to Phlius, where, being asked by King Leon what

was his profession, he replied that he was a philosopher (or lover of wisdom), declaring that the name of sage (*sophos*) belonged solely to the Divinity. With augmented knowledge he returned home, where he now founded a philosophical school with great success. He laid claim to supernatural powers, and his extraordinary qualities gained over great numbers of the noble and wealthy classes. Three hundred of these were formed into a select fraternity or order, which has been frequently compared with the still more famous order founded by Loyola in modern times. The members were bound by a vow to Pythagoras and each other, for the purpose of cultivating the religious rites and ascetic observances of their master, and of studying his system of philosophy. They thus formed at once a philosophical school and a religious order, which in time also assumed the character and exercised the influence of a political association. This influence, which became very considerable, was constantly exerted in the interest of the aristocratic party. The democratic party (perhaps, also, at times, an unfriendly aristocratic faction) reacted against the growing power of the order. At the head of this opposition party in Crotona was Cylon, a rich and respectable citizen, whose enmity Pythagoras had excited by refusing to receive him among his scholars. In revenge Cylon once attacked the house of Milo, where a number of Pythagoreans were assembled, surrounded it with his partisans and set it on fire. Forty persons perished, and but few escaped. Pythagoras was probably not in the house. Other authorities set down this event long after the death of Pythagoras, who, they say, was simply banished by Cylon to Metapontum. He fled to the Locrians, and when these refused to receive him, to Metapontum, where, according to tradition, he perished from hunger. For his system of philosophy see **PYTHAGOREANISM**. Consult Burnet, J., 'Early Greek Philosophy' (2d ed., London 1908); id., 'Greek Philosophy' (London 1914); Cantor, M., 'History of Mathematics' (Leipzig 1900); Fink, K., 'Brief History of Mathematics' (Chicago 1900); Gompertz T., 'Greek Thinkers' (London 1901-05); Gow, J., 'Short History of Greek Mathematics' (New York 1884); Milhaud, 'La Science Grecque'; id., 'Philosophes géomètres'; Ueberweg, F., 'History of Philosophy from Thales to the Present Time' (2 vols., New York 1884); Windelband, W., 'History of Ancient Philosophy' (New York 1899); Zeller, E., 'Die Philosophie der Griechen in ihrer geschichtlichen Entwicklungen' (5th ed., Leipzig 1892; English trans. by Alleyne, S. F., of 4th ed., 2 vols., London 1881).

PYTHAGORAS OF RHEGIUM, rê-jî-ûm, Greek sculptor: b. Samos toward the end of the 5th century before Christ. He was noted for his skill in giving the finest and justest proportions to his statues which often represented the human body in attitudes most difficult to represent. Such were his 'Limping Philoctetes' (in bronze); his 'Apollo in Combat with the Dragon'; his 'Duel of Eteocles and Polynices'; 'Europa and the Bull.' His favorite subjects were victors in the public games, and it was his habit as an artist to elaborate the details of his figures; he was learned as an anatomist, and in his statues the hair, sinews, and even

veins were represented with life-like distinctness and individuality.

PYTHAGOREAN THEOREM, the 47th proposition of the first book of Euclid's Elements, which shows that in any right-angled triangle the square on the hypotenuse is equal to the sum of the squares on the other two sides.

PYTHAGOREANISM, the philosophical doctrine of the Pythagoreans, or followers of Pythagoras (q.v.). The system of the Pythagoreans was comprehensive and included a theory of being, that is, a religious cult; a metaphysic; a cosmological theory, and a mathematical theory.

Pythagorean Cult.—The Pythagoreans believed in immortality and the transmigration of souls. As they consequently considered all animals to partake of human nature, they forbade the eating of flesh, and even that of beans, which they somehow associated with flesh. They formed a close corporation, and it was considered sinful to reveal any imperfections in the mathematical work of the school to those outside.

Pythagorean Metaphysics.—The Pythagoreans taught that the essence of all things was number; that everything in its final analysis could be resolved into number. This statement, which is recorded in Aristotle's Metaphysics, where he is enumerating the Greek schools of philosophy, has occasioned much dispute. We may perhaps see in this doctrine the basis of the 10 antitheses of Pythagorean teaching, especially that of the opposites, odd and even, the definite and indefinite, which are placed first in the list. Number was also an idea in which these opposites were each included, and was, therefore, sometimes spoken of as harmony. But other interpretations of the Pythagorean number make unity and duality as the root notion, and pronounce that these terms may be reduced to the opposition of the spiritual and corporeal, of form and of substance, of the Supreme Being and the material world. The Deity is the one, the Original Unity, the Infinite, out of which all finite things have come. The opposition between the limited or finite and the unlimited or infinite is by some philosophers regarded as the fundamental idea in the Pythagorean number. It is possible that the doctrine was from the first propounded as a vague generalization which might be and was interpreted in different ways by different members of the school. It is evident that nothing can exist without number, as is stated in the apocryphal Book of Wisdom, in some respects a product of Alexandrian Neo-Pythagoreanism. The numbers themselves are divisible into odd and even, thus suggesting the contrast between the limited and unlimited, the conditioned and the unconditioned, the relative and the absolute, matter and spirit, man and God. On the other hand, it is possible that the Pythagorean number was not arithmetical but geometrical. The great disciple of Pythagoras in the time of Socrates was Philolaus, but of the writings in which he expounded his views only fragments survive, and these are of doubtful authenticity. Philolaus may have been under the influence of Democritus, and his theory of number have been based on geometrical axioms and the intervals in the sounds struck from the seven-

stringed lyre. Probably he was an atomist. The individual atom would in that case represent to him a material spatial point, two of which made a line, three a surface, four a solid; of these solids, represented always by even numbers, the constituents of earth were cubical; those of fire tetrahedral, those of water icosahedral, etc. From the use of numbers as the ontological basis of things the passage was easy enough to the wild and fanciful application of them as mere symbols. Thus the later Pythagoreans made the soul correspond with the number six, while seven was the counterpart of reason and health. The imagination here stepped in and with curious ingenuity labored to give a rational basis to these axioms. Hence the famous oppositions of this philosophical sect; namely (1) limited and unlimited; (2) even and odd; (3) one and many; (4) right and left; (5) male and female; (6) rest and motion; (7) straight and crooked; (8) light and darkness; (9) good and evil; (10) square and rectangle. It will be perceived that in these oppositions the idea of completeness, as represented by an even number, and incompleteness by an odd number is the ruling element, and in the idea of incompleteness is implied the potentiality of indefinite extension, multiplication or variation. From the very beginning of Pythagoreanism many semi-mystical, semi-scientific speculations were made concerning square numbers; triangular numbers, of the form $\frac{X^2+3X}{2}$, representing triangular regularly

spaced aggregates of points; and rectangular numbers of the form $X^2 + X$, representing rectangular aggregates of points.

Pythagorean Cosmology.—Pythagoras, or at least the Pythagoreans, had some vague idea of a heliocentric solar system. They taught that the universe had as its centre a fire round which the earth and stars revolved. This central fire was not identified with the sun; the stars were luminous from reflecting its light. They taught that this fire was not visible from the earth; that there was a counter earth which made up with the five known planets, the fixed stars, sun and moon, 10 celestial phenomena. The distance of the spheres from the central fire was determined according to simple numerical relationships. The harmony of the spheres was a melodious sound resulting from the revolution of the heavenly bodies in accordance with the intervals of their distance from the central fire. The Pythagoreans discovered the connection between the length of the string in a lyre and the character of the note which was sounded on percussion, and developed a theory of the musical scale. Indeed this seems to have been the source of their medical and mathematical researches.

Pythagorean Geometry.—The Ionic school of Greek philosophy imported geometry from Egypt into the Greek world of intellectual activity. Its early development in Europe was mainly due to the followers of Pythagoras, who himself enunciated the theorem now known as the 47th proposition of the first book of Euclid, which says that the square of the hypotenuse of a right angled triangle is the sum of the squares on its legs. The three propositions, arithmetical, geometrical and harmonical, were known to them, having been intro-

duced into Greece by Pythagoras, who learned them from the inventors, the Babylonians. (See NEO-PYTHAGOREANS; PYTHAGORAS). Consult Burnet, 'Greek Philosophy' (Part I, London 1914); Gomperz, 'Greek Thinkers' (tr. New York 1901); Zeller, 'Die Philosophie der Griechen in ihrer geschichtlichen Entwicklung' (5th ed., Leipzig 1892; tr. London 1881).

PYTHEAS, pith'ê-as, Greek navigator: b. Massilia (Marseilles) in the 4th century B.C. He made two voyages of discovery along the western coast of Europe from Gibraltar to Iceland. The first voyage extended along the western coast of Europe, through the English Channel, and after somewhat extensive explorations in Britain he proceeded northward and reached Thule, which seems identical with Iceland. Here he was deterred from farther advance by dense fogs and considered himself to have reached the point where the earth ended. He described the fog as a molluscous substance, in which earth, air and sea mingled and in which the universe was suspended. His second voyage seems to have extended along the coast of Denmark and to the Baltic. His accounts of his voyages were received as fables by the ancients, and though celebrated as a navigator and mathematician, little is known of him excepting through the brief and adverse criticism of later writers, among whom are Strabo and Pliny. His accounts were without doubt in the main correct, but the loss of his works makes it difficult to ascertain his real status. He was said to have been the first to determine the sun's meridian altitude at Marseilles at the summer solstice by means of a gnomon. The scanty fragments remaining of his writings were published by Arvedson (1824); Mullenhoff, 'Deutsche Alterthums-kunde' (Berlin 1870).

PYTHIAN GAMES, in ancient Greece, a name given one of the four national festivals or games, instituted in early times in honor of Apollo, the conqueror of the python. They were celebrated in the neighborhood of Delphi (formerly called Pytho), in the Crissæan fields, which for this purpose contained a hippodrome or race-course; a stadium of 1,000 feet in length, and a theatre, in which the musical contests took place. According to the popular mythological legend the Pythian Games were instituted by Apollo himself. They seem to have been originally only a musical contest, which consisted in singing a hymn to the Pythian god. Until about 586 B.C. they were under the management of the Delphians and took place at the end of every eighth year; but after that date they were conducted by the Amphictyons and were celebrated at the end of every fourth year and prizes were added for flute-playing, athletic sports and horse and chariot racing. Eventually contests in tragedy and other kinds of poetry, painting, sculpture and historical narratives were introduced. At first the prizes were silver or gold, but afterward they consisted of the laurel wreath and the symbolic palm-branch. The statues of the victors were erected in the Crissæan plain. They continued to be celebrated, it is believed, until the end of the 4th century. Consult Gardiner, 'Greek Festivals and Sports' (1910).

PYTHIAS, pith'î-as. See DAMON AND PHINTIAS.

PYTHIAS, Knights of. See KNIGHTS OF PYTHIAS.

PYTHON, in Greek mythology, was the son of Gæa, an enormous serpent which was produced from the mud after the flood of Deucalion. It lived in a cave on Mount Parnassus and was slain a few days after its birth by Apollo. Python really represents the fogs and vapor-clouds which arise from ponds and marshes and are dispersed by Apollo with his shafts—the rays of the sun. Consult Pascal, C., 'Studi di antichità e mitologia' (1896).

PYTHON, a serpent of the subfamily *Pythonina* of the boa family. Pythons differ little from boas (see BOINÆ), but, except a small, aberrant species in Mexico, are found in Africa, India and eastward to Australia. They rival the boas (q.v.) in size and strength and have similar habits, hanging motionless from trees by their prehensile tails or lurking in the grass or in water where animals are likely to come or at the drinking places. They are especially fond of rocky places, affording snug retreats and are generally known in Africa as "rock-snakes." Hence they pounce on their victims, which are instantly enveloped in folds of their flexuous and muscular bodies and crushed and rolled into a compact mass. Greatly exaggerated stories are told of the huge creatures these serpents are able to swallow, but, although a tiger or an ox might be killed by the great Indian python, a crushed dog or goat (horns and all) is the limit of its power to eat. The process of swallowing is very slow and many weeks may elapse before another meal is desired. In fact, however, small rodents and birds form the greater part of their fare and these are more frequently caught. These great serpents are justly dreaded by the natives of the regions they inhabit and the literature of travel, ancient and modern, abounds in narratives of their terrible deeds, and many legends and superstitions have clustered about them, especially in the Orient. Few trustworthy records exist of their having attacked human beings, however, and most of the species are readily tamable. They are nocturnal in disposition, hiding in holes or shady tree-tops during the day.

All pythons lay from 50 to 100 eggs on the ground in some dry, grassy place, and the female coils about them, guarding and warming them for about two months when they hatch. The boas, on the contrary, bring forth their young alive.

The biggest pythons are those of southern Asia, the first place belonging to the netted python (*Python reticulatus*) of Indo-China and the Malay Archipelago, which sometimes exceeds 30 feet in length and is perhaps the largest kind of serpent known. It is light yellowish brown with squarish black markings and its skin glitters in the sunlight with splendid prismatic hues. It abounds in hot, low-lying regions and has a savage disposition. Its rate of growth is slow and it probably lives to a great age. The adigar (*P. molurus*) of all India, Ceylon and Malaya, reaches nearly the same length and is of heavier build; it varies from yellowish to dark brown in ground-color, with elongate, irregular dark blotches. The three African species known as

"rock-snakes," are smaller, none exceeding 18 feet long. One of them, the royal python (*P. regia*), dark brown, with a row of light spots along the back, is the species most often seen in traveling menageries. Another (*P. seba*) is called "fetch-snake," on account of the superstitious regard paid it by the negroes of the West Coast. It is marked with many dark zig-zag cross-bars and a dark line along the spine. Australia possesses several pythons, which are smaller and more active than the tropical species. Two, the carpet-python and the diamond snake, are common and well known; they are pests of the poultry-yard, but useful as destroyers of rats and rabbits.

ERNEST INGERSOLL.

PYTHONINÆ. See BOIDÆ; PYTHON.

PYTHONOMORPHA, a suborder of fossil marine reptiles whose remains are found in Cretaceous rocks of Europe, the Americas, New Zealand and South Africa. There are about 120 vertebrae in the vertebral column. The skull was long and much resembled that of the lizard. The two pairs of limbs were used as paddles in swimming. The mouth permitted these reptiles to seize large prey which they held by means of their stout conical teeth. Kansas has yielded many well-preserved specimens from its chalk-beds. Complete skeletons measuring 30 feet in length have been found. The chief divisions of the Pythonomorpha are Tylosaurus, Platecarpus, Clidastes and Mosasaurus. The last named was the largest member of the group, sometimes reaching a length of 40 feet. Consult Osborn, Henry Fairfield, 'A Complete Monasaur Skeleton' (in 'Memoirs of the American Museum of Natural History,' Vol. I, part iv, New York 1899); Von Zittel and Eastman, 'Textbook of Palæontology' (Vol. II, New York 1902); Williston, 'On Monasaurs, etc.' (in *Kansas University Quar-*

terly, Vol. II, Lawrence 1893); id., in 'University Geological Survey of Kansas' (Vol. IV, Topeka 1898); Williston and Case, 'Kansas Monasaurs' (in *Kansas University Quarterly*, Vol. I, Lawrence 1892).

PYX, anciently any casket and in particular a jewel-case. The present significations of the word are: (1) The vessel, of gold or silver, in which, in Catholic churches, the blessed sacrament is reserved; called also ciborium; and the small silver-gilt vessel in which the host is carried to the sick for administration at their homes. In former times the pyx had the form of a dove and was suspended above the altar; in present usage it is reserved in the tabernacle or shrine above the high altar. (2) The box or chest in which, at the English mint, specimens of the coinage are deposited, to be tested by a jury of goldsmiths about once in three years; this test is called the "trial of the pyx."

PYXIE. The pyxie, or flowering moss (*Pyxidantha barbulate*), is one of the most beautiful and early-flowering plants of the moist, sandy, pine-barren regions of New Jersey and North Carolina. It is found only in certain localities even in this restricted district, but is abundant in its chosen haunts, blooming in April. The pyxie belongs to the *Diapensia* family, very closely related to the heather tribe, and is a small, evergreen, shrubby plant, lying, cushion-like, flat on the sand, and having long, tapering branches trailing in all directions. The small, rigid, pointed leaves are tinged with red at blossoming time and are very numerous, but are nearly hidden by the profusion of waxen, symmetrical, five-lobed flowers, coral-tinted in the bud, creamy white when open. The twin anther-cells of the five anthers are globose and transversely valved, whence the Greek generic name, meaning box-anther.

PYTHON (*Python molurus*)

Q

Q the 17th letter of the English, Latin and other alphabets of western Europe. As in Latin so in English it is always followed by the vowel *u*: as in English so probably in ancient Latin *qu* was equal to *cu* or *kw*: *q* is, therefore, a superfluous letter, and has no place in a scientific alphabet, save as standing for some sound differing from that of *k*: in A. J. Ellis's palæotype alphabet *q* stands for nasal *ng*. Some of the ancient Latin grammarians regarded *Q* as a contracted form of *CV* (that is *cu*); but others, and with them modern philologists, recognize in *Q* a modified form of the koppa of early Greek *Q*, derived from the Phœnician alphabet. (See ALPHABET). This character occurs in very ancient Latin inscriptions; but later the down stroke was written aslant, *Q*, whence the form *Q*. *Q* was not employed in Anglo-Saxon writing, *cw* being used instead: *cwen*, queen; *cwellan*, to quell; nor was it used in early German writing, except for words borrowed from Latin; but afterward words of native Germanic origin were spelled with *q*: *quālen*, to torment; *quer*, athwart.

In some systems for the transliteration of the semitic languages *Q* is used for the Hebrew *q*, Arabic *q*. The sound *Qu* in Germanic languages is cognate with what appears to be an unlabialized guttural in the mother tongue of the Indo-Europeans. The labialized guttural *Q* is often related to pure labial sounds: thus the Latin *quattuor*, "form," corresponds to the Oscan *petora*. In words borrowed from the French, such as *coquette*, *Qu* is pronounced as a simple *k*. *Q* stands for "Quintus." *Q. E. D.* for Lat. *quod erat demonstrandum*, "which was to be proved"; *Q. E. F.* for *quod erat faciendum*, "which was to be done"; *qr.* for "quire" or "quarter"; *qt.* for "quart"; *q.v.* for Lat. *quod vide*, "which see"; *q.d.* for Lat. *quasi dictum*, "as if said"; *Q. C.* for "Queen's Counsel."

QUA (kwā) BIRD. See HERONS.

QUACKENBOS, kwāk'ën-bōs, George Payn, American educator: b. New York, 4 Sept. 1826; d. New London, N. H., 24 July 1881. He was graduated at Columbia in 1843 and admitted to the bar. Later he abandoned law and for many years conducted a large private school in New York. He published 'Advanced Course of Rhetoric and Composition' (1854); 'School History of the United States' (1857); 'Natural Philosophy' (1859), and many other once popular textbooks.

QUACKENBOS, John Duncan, American physician, son of G. P. Quackenbos (q.v.): b. New York, 22 April 1848. He was graduated from Columbia in 1866 and from the College of Physicians and Surgeons in 1871, and has since practised in New York. He became ad-

junct professor of English at Columbia in 1884, and was professor of rhetoric in Barnard College 1891-93. He is a specialist in mental diseases and has published, among various other works, 'History of the World'; 'History of Ancient Literature'; 'Tuberculosis'; 'Typhoid Fever'; 'New England Roads and Roadside Attractions'; 'Hypnotism in Mental and Moral Culture'; 'Hypnotic Therapeutics'; 'Enemies and Evidences of Christianity'; 'Magnhild' (1919), etc.

QUACKENBUSH, kwāk'ën bûsh, Stephen Platt, American naval officer: b. Albany, N. Y., 23 Jan. 1823; d. Washington, D. C., 4 Feb. 1890. He entered the navy as midshipman in 1840, received rank as lieutenant in 1855 and lieutenant-commander in 1862. In the early part of the Civil War he had charge of the *Delaware*, *Unadilla*, *Pequot*, *Patapsco* and *Mingo* in the blockading squadron, covered General Burnside's army at Aquia Creek and Roanoke Island, participated in the battles of Elizabeth City and New Berne, N. C., engaged the Confederate batteries at Winton, N. C., and destroyed the town. He later took part in the engagements at Sewell's Point Landing, Wilcox Landing and Malvern Hill and received at the last-mentioned place a wound from which he lost his right leg. In 1863 he captured the *Princess Royal* loaded with materials for a Confederate ironclad. In 1864 while dredging Charleston Harbor for torpedoes his ship, the *Patapsco*, was struck by a torpedo and sunk. Later he was in command of the *Mingo*, protecting Georgetown, S. C. He became rear-admiral in 1884 and was retired in 1885.

QUADI, kwā'di, an ancient powerful people of southeastern Germany, of the Suevic race. They inhabited the country bounded by Mount Gabreta, the Hercynian forest, the Sarmatian Mountains and the Danube; their neighbors being the Gothini and Osi on the north, the Jazyges Metanastæ on the east, the Pannonians on the south and the Marcomanni on the west. With the last-named people they were on terms of alliance. In the reign of Tiberius the Romans erected a kingdom of the Quadi; but in the reign of Marcus Aurelius the Quadi joined the great German confederacy against the empire, and in 174 were on the point of destroying the imperial legions in a great battle when a sudden storm, attributed to the prayers of the Christian soldiers in the emperor's army, enabled the Romans to recover from their confusion and achieve a complete victory. The independence of the Quadi was recognized by Commodus in 180. They disappear from history about the close of the 4th century.

QUADRAGESIMA, the period of the 40 days' fast preceding Easter: the season has a like name in Greek, *Tesserakosté*, fortieth. The first Sunday of Lent is sometimes called Quadragesima, but in the Roman calendar it is *Dominica prima Quadragesimæ*, first Sunday of Lent and the Sundays following are denominated, respectively, the second, third and fourth of Quadragesima, Passion Sunday (*Dominica Passionis*), and Palm Sunday (*Dominica Palmarum*). In the Book of Common Prayer these six Sundays are called the first, second, third, fourth and fifth of Lent and "Sunday next before Easter"; but this Sunday is also styled in England and the United States "Passion Sunday," and its week "Passion Week"; its familiar name among Catholics is "Holy Week."

QUADRANGLE, a square or four-sided court or space surrounded by buildings, as often seen in the buildings of a college. Also in geometry, a figure having four angles, and consequently four sides.

QUADRANT. See SURVEYING.

QUADRATE BONE, the squarish bone developed in reptiles and birds, by means of which the lower jaw is articulated or joined to the skull. The lower jaw of these forms is thus not articulated directly or of itself to the skull, as in mammals; and in reptiles and birds each half of the lower jaw is composed of a number of distinct pieces. In mammals, on the contrary, the lower jaw consists simply of two halves united together in front. The *os quadratum*, or quadrate bone, which thus forms a characteristic structure of birds and reptiles, is generally regarded as corresponding in mammals to one of the little bones or auditory ossicles of the internal ear, named the malleus. See EAR.

QUADRATURE OF THE CIRCLE.

The problem involved in the quadrature of the circle requires the determination of the length of a straight line such that the square constructed thereon shall have an area equal to that of a given circle. It can be shown in a variety of ways that, if r is the radius of the circle, the area will be equal to πr^2 where π can only be obtained approximately in terms of a finite number of fractions. On the other hand, it has become a matter of general information that the quadrature of the circle is impossible, and this is true only when the ancient Greek problem is understood, which involves a serious limitation; that is, the quadrature must be effected by means of a geometrical construction in which the mathematician is limited to the use of but two instruments, the straight edge and a pair of compasses. The problem is not solved, therefore, if any other instrument or any equivalent analytic method is employed. For 4,000 years innumerable attempts have been made to discover this construction, all destined to fail, as it was demonstrated by Lindemann in 1882 to be impossible. In reaching this conclusion we are confronted by the fundamental question: What geometrical constructions are, and what are not, possible, when restricted to the use of these instruments? In analysis, operations correspond to constructions. The operation, $a \times b$, involves taking b units a times, which, with an assumed unit of length, is equivalent to laying off a line having $a \times b$ units of length, which is accomplished by using the method of propor-

tions. In a similar manner, the *rational* operations of addition, subtraction, multiplication and division find a geometrical solution involving the straight edge alone.

Irrational operations are divided into algebraic and transcendental. Any operation that involves the extraction of a square root only presents the simplest case of an algebraic irrationality, and any construction involving the determination of the points of intersection of two circles, or a circle and straight line, leads to an equation of the second, of the fourth or of some higher degree, whose solution involves the extraction of square roots and rational operations only. Conversely, the necessary and sufficient condition that unknown quantities can be constructed with the straight edge and compasses is that the unknown quantities can be expressed explicitly in terms of the known by an analytic expression involving only a finite number of rational operations and square roots. In other words a Euclidean geometrical solution is impossible when no corresponding algebraic equation exists. When a number like $\sqrt{2}$ is the root of an algebraic equation with integral coefficients, for example, $x^2 - 2 = 0$, and still can not be expressed exactly in terms of a finite series of numbers it is an algebraic irrational number. When the number, like e , the natural base in the theory of logarithms, or π , the ratio of the circumference to the diameter, is not the root of any algebraic equation, with integral coefficients, it is a transcendental number. Lindemann provided that π is a transcendental number and, hence, since it is not the root of any algebraic equation, it cannot be constructed to an assumed unit by the extraction of square roots, that is, by using the straight edge and compasses.

The possibility of a geometrical solution of a problem in general depends upon a theorem in the theory of numbers to the effect that *the degree of the irreducible equation satisfied by an expression composed of square roots only is always a power of 2*; whence, *if an irreducible equation is not of degree 2^n , it cannot be solved by square roots*.

Next to the squaring of the circle, the most famous problems of antiquity are the *Delium problem of the duplication of the cube* and the *trisection of an arbitrary angle*. Granting the preceding general theorem, these are easily shown to be impossible when restricted to the straight edge and compass.

The duplication of the cube requires the determination of the edge of a cube x , such that its cube shall be twice the volume of a given unit. That is $x^3 = 2$. This equation is irreducible, since otherwise $\sqrt[3]{2}$ would be rational. Moreover, the equation is a cubic and its degree is not of the form 2^n . Hence the solution is in general impossible.

The problem of the trisection of an arbitrary angle corresponds to the solution of

$$x^3 = \cos \phi + \sqrt{-1} \sin \phi$$

and it follows that in general this is impossible by Euclidean methods.

History.—The quadrature of the circle is attempted in the Rhind Papyrus (2000 a.c.), the oldest known mathematical work, in which Ahmes, an Egyptian priest, lays down the empirical rule: "Cut off one ninth of the diameter;

the square on the remainder will equal the area of the circle.³ This rule affords $\pi = \left(\frac{16}{9}\right)^2 =$

3.16, a value reasonably accurate as compared with $\pi = 3$, the value assumed in the Bible (1 Kings vii, 23; Chronicles iv, 2). Archimedes (200 B.C.) invented the method still used by students of plane geometry that depends on inscribing and circumscribing regular polygons, which, save for an improvement by Huygens (1654), remained in use until the invention of the infinitesimal calculus by Newton and Leibnitz in the last quarter of the 17th century. Hippocrates of Chios (470 B.C.) was the first to investigate areas bounded by curves and to bring into prominence the problems of squaring the circle and duplication of the cube. According to Philoponus, the Athenians were suffering from a severe plague of typhoid fever in 430 B.C., and were told by the oracle at Delos that Apollo required an altar in the form of a cube twice the size of the one existing. A new one was, therefore, constructed, having each edge twice the length of the old one, but the plague was worse than ever. Suspecting some mystery, confirmed by the insistence of the oracle, the Greeks applied to Plato, the most illustrious of their geometers, and were referred by him to Hippocrates. He succeeded in reducing the problem to the determination of two mean proportionals: for, if $a : x = x : y = y : 2a$, then $x^2 = ay$ and $y^2 = 2ax$, the equations of two parabolas, which intersect in a point whose abscissa is $x^2 = 2a^2$. This is equivalent to a graphical solution by means of conics, but to draw the curves, a different instrument would be required than those prescribed by Euclid. The problem was thereafter known as the Delian problem. The *Cissoïd of Diocles* (150 B.C.) and the *Conchoid of Nicomedes* (150 B.C.) are curves of the third and fourth degree, respectively, invented for the special purpose of duplicating the cube and trisecting any angle. The curve known as the *quadratrix of Dinostratus* (350 B.C.) which, however, had previously been constructed by Hippias of Elis (420 B.C.) for the trisection of the angle, sufficed also to determine the length of a circular arc and for the quadrature of the circle. It belongs to the class known in modern times as *integral curves*, since the ordinate can be expressed as an integral, such a curve being known to the ancients as a *quadratrix*. If OA and OB are two perpendicular radii of a circle and two points M and L move with constant velocity one upon the radius OB and the other upon arc AB, such that starting from O and A at the same time they both arrive simultaneously at B; then the intersection of OL and MP drawn parallel to OA is a point on the quadratrix. The ordinate, y, is proportional to θ , the angle between OL and OA, and since $y = 1$, when $\theta = \frac{\pi}{2}$, $\theta = \frac{\pi}{2} y$. But $\theta = \tan^{-1} \frac{y}{x}$, the equation

of the quadratrix becomes $\frac{y}{x} = \tan \frac{\pi}{2} y$.

It cuts the axes of X at the point whose abscissa is $x = \lim_{y=0} \frac{y}{\tan \frac{\pi}{2} y} = \frac{2}{\pi}$.

It follows that the radius of the circle is the mean proportional between the length of the

quadrant and the abscissa of the intersection of the curve with the axis of X. Hence any apparatus that will describe the quadratrix will enable us to determine π graphically. Evidently the curve $y = \sin \pi x$ is much more convenient for this purpose, since π is one of the ordinates of this curve when x equals zero; but this curve does not appear to have been used by the Greeks. It is called the *sinusoid*, the axis being vertical, and any transcendental apparatus which will trace the sinusoid by continuous motion would afford a geometrical construction of π . Such an apparatus has been invented recently by a Russian engineer, Abdank-Abakanowicz, and constructed by Coradi of Zürich. It is called the *integrator*, and with its aid it is possible not only to lay off π but to trace the *integral curve*.

$Y = F(x) = \int f(x) dx$, when the differential curve $y = f(x)$ is given.

The rise of modern analysis after Newton and Leibnitz developed many new methods for the evolution of π , the best known being the so-called series of Leibnitz,

$$\pi = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \dots$$

After the invention of logarithms by Napier (1614), Euler, by the introduction of complex quantities, developed the celebrated relation between the Napierian base e and π ,

$$e^{ix} = \cos x + i \sin x$$

which for $x = \pi$ reduces to the most remarkable relation in mathematics,

$$e^{i\pi} = -1.$$

The modern proofs of the transcendence of π are based upon this relation, since they all depend upon that of e . In 1873 Hermite (*Sur la Fonction exponentielle*, *Comptes rendus*, 1873) first proved the transcendence of e , and this was followed, in 1882, by an analogous demonstration for π , given by Lindemann (*Über die Zahl π* , *Mathematische Annalen*, XX 1882). This demonstration is equivalent to proving that the Euclidean problem of the quadrature of the circle is impossible, and closes in this generation a question that has occupied mathematicians for 4,000 years. The long and difficult proofs of Hermite and Lindemann have been much simplified, first by Weierstrass (*Berliner Berichte*, 1885), and in particular by Hilbert, Hurwitz and Gordon (*Mathematische Annalen*, Vol. XLIII). The questions involved treated without requiring a knowledge of the calculus have become familiar to English mathematicians through the translation by Beman and Smith of Klein's *Famous Problems of Elementary Geometry* (1897). Consult also the chapter on 'The History and Transcendence of π ', in *Monographs on Topics in Modern Mathematics* (New York 1911), by D. E. Smith.

J. BRACE CHITTENDEN, PH.D.

QUADRIENNIUM UTILE, kwäd-ri-ën'-l-üm ü-ti-lä (Latin, meaning "four years useful"), a phrase in Scotch law, referring to the four years after majority, during which period a person may set aside or revoke any deed executed during his minority, if such deed is to his prejudice. The same law existed among the Romans, to protect the rights of minors by giving them, after majority, an opportunity to revoke any deed which had been made to their disadvantage when they were inexperienced minors or, in the eyes of the law, infants.

QUADRIGA. See CHARIOT.

QUADRILATERAL, a common name for the four fortresses of northern Italy: Mantua, Legnago, Peschiera and Verona, which form an outwork to the bastion of the mountains of the Tyrol. They have figured prominently in the wars between Austria and the several Italian states. There exists also a combination of four fortresses in Poland called the Polish Quadrilateral.

QUADRILATERAL. See POLYGON.

QUADRILLE, kwād-ril, or kă-dril', (1) a dance of French origin, now forgotten in most civilized countries of the globe, which consists generally of five consecutive figures or dance movements, danced by four couples, each forming the side of a square; or by four sets (often pairs) of couples. (2) Also an obsolete game of cards played by four persons. The game is celebrated by Pope in 'The Rape of the Lock.'

QUADRIVIUM, the name given in the Middle Ages to the four mathematical branches of study, arithmetic, music, geometry and astronomy, in contradistinction to the Trivium, which consisted of the three remaining branches taught in the mediæval schools, and which consisted of grammar, rhetoric and dialectics, the whole comprehending what was called the seven liberal arts. This program of study was outlined by Plato in the 'Republic.'

QUADROON, or **QUARTEROON**, a person of mixed blood, usually one who is one-quarter negro and three-quarters white; that is, one of whose grandparents was white and the other negro, and one of whose immediate parents was white and the other mulatto.

QUADRU MANA, the name applied by Cuvier and others to denote the order of "four-handed" mammalia represented by the lemurs, monkeys and apes, from the fact that these forms agree in possessing a great toe so constructed as to be capable of opposing the other digits of the feet, instead of being placed parallel with the other toes, thus forming a kind of "hand" adapted for supporting the foot on the ground. Cuvier separated man as a collateral order *Bimana* or "two-handed" mammalia. But in modern zoology, man is included in one order with the apes and monkeys — the order *Primates* (q.v.).

QUADRUPLE ALLIANCE, a union of four sovereigns or states to forward their common policies. Notable among such unions was the alliance between Great Britain, France and the German Empire, concluded at London in 1718, in which Holland joined 1719; its objects were to secure to the house of Hanover the succession to the British Crown; to secure France to the house of Bourbon; and to prevent the union of France and Spain under one crown. Another memorable quadruple alliance was that of Austria, Russia, Great Britain and Prussia, formed in 1814 to regulate the political system of Europe after the fall of Napoleon. In 1834 England, France, Spain and Portugal entered into an alliance to put down Don Carlos and his partisans.

QUADRUPLEX TELEGRAPHY. See ELECTRICAL TERMS.

QUÆSTOR, kwēs'tôr, the title of a class of magistrates in ancient Rome who had charge

of the pecuniary affairs of the commonwealth: they were the treasurers of state. Of these one, *quæstor urbanus* or *q. æarii* (urban quæstor, quæstor of the treasury), who remained at Rome, administered the public revenues and expenditures. Other quæstors, called provincial or military quæstors, served as assistants to the proconsuls or proprætors who governed the several provinces: their duty was to provide for the payment and provisioning of the troops, to collect the imposts and, in the absence of the governor, to act in his stead. In very early times there was in Rome an official styled *quæstor parricidii* (tracker of murder) who prosecuted persons charged with capital offenses. A quæstor was ex officio entitled to a seat in the Senate.

QUAGGA, kwäg'gā, a species of the horse (*Equus quagga*), nearly allied to the zebras, formerly found on the plains of southern Africa, but now quite extinct. It was striped like the zebra, but did not possess bands on the limbs. The color was dark brown on the head, neck and shoulders, the back and hind quarters being lighter, while the croup was russet gray. The under parts of the body were white, the upper parts of the legs and tail being marked by whitish bars. The quagga was smaller than the zebra, and bore a closer resemblance to the horse. The ears were short, the head being relatively small. The tail was tufted. These animals were gregarious, the herds which inhabited the Kaffrarian plains numbering each several hundreds of individuals, which would mingle with the zebra herds. The quagga was active, nimble and elegant in its movements. The Bushmen and Kaffirs esteemed the flesh as good palatable food, and these animals were on the same account unremittingly pursued by the lion. It was tamed without much difficulty, but domestication apparently altered its disposition and rendered it dull and less active in habits. The Dutch colonists were said to be in the habit of keeping quaggas along with their cattle which the quaggas defended from the attack of hyænas and other carnivora by trampling on the invaders and otherwise injuring them. The quagga bred with the common horse, and a mixed race of this kind, possessing great beauty of form, and retaining in a large degree the characteristic markings of the quagga, is said to have existed in England at one time. The name "quagga" was derived from the cry of the animal, which may most nearly be expressed by the word *Coua-ag*. The animal has received a variety of names from authors: thus Pennant terms it the *quacha*, and Masson the *opeagha*. Consult Bryden, 'Nature and Sport in South Africa' (1897), and early writers on South Africa, especially Harris, Lichtenstein and Gordon-Cumming.

QUAGLIO, kwa'le-ō, name of a family of painters, originally belonging to Laino, Lago Maggiore, Italy, but afterward dwellers in Munich. The most eminent among them, Domenico (b. Munich, 1 Jan. 1786; d. Hohenschwangau, 9 April 1837), was for 11 years decorative painter for the Munich Theatre. He subsequently turned his attention to oil-painting and also executed etchings and lithographs. He traveled through Germany, along the Rhine, to the Netherlands, to France, Switzerland and Italy, with the object of studying mediæval

architecture as a subject for painting. During the latter period of his life he was engaged by the Crown Prince Maximilian of Bavaria in the restoration and decoration of the castle of Hohenschwangau. He was member of the Academy of Munich and Berlin and one of the first German artists to produce in painting architectural effects of a thoroughly artistic quality. He also published books on the mediæval buildings of Bavaria; on the most noteworthy buildings of Munich, and on the architectural statuary of Bavarian mediæval buildings. His brother, LORENZ QUAGLIO (b. Munich, 19 Dec. 1793; d. there, 15 March 1869), directed his studies to genre painting and lithography. In this latter department of art he reached the highest excellence. His paintings consist of incidents from mediæval life and his landscapes are taken from the highlands of Bavaria. The third brother, SIMON QUAGLIO (b. Munich, 23 Oct. 1795; d. there, 8 March 1878), was scene painter and decorator to the Hof Theatre and executed many exceedingly clever pictures in oil, chiefly of architectural subjects and distinguished for faultless perspective, beauty of design and brilliancy of coloring. ANGELO, son of the last (b. Munich, 13 Dec. 1829; d. there, 5 Jan. 1890), was scene painter to the Bavarian Hof Theatre and by his architectural decorations gained a world-wide reputation.

QUAHA, the side-striped African jackal (*Canis lateralis*). See JACKAL.

QUAHOG, or **ROUND CLAM**. See CLAM.

QUAI D'ORSAY, *kā dōr-sā*. See PARIS.

QUAIL, one of several partridges (q.v.); in the eastern United States the bob-white (*Colinus virginianus*) and on the Pacific Coast partridges of other genera. The eastern bob-white requires no description beyond a statement of the differences between the sexes. Besides being larger, the male has the superciliary line and throat pure white, these parts in the female being buff and without black borders and she also has the colors generally more blended. The bob-white is widely distributed throughout the eastern United States; on the Atlantic Coast it barely enters Maine, farther west it is found northward in New York, Ontario and Minnesota; southward it is abundant in the Gulf and South Atlantic States and westward reaches to the elevated central plains from South Dakota to Texas. Farther westward at many points in this country, in Jamaica and other West Indian islands this species has been very successfully introduced, but similar attempts in Europe seem to have failed. The Florida and Texan birds present extremes of variation recognized as sub-species and a related species (*C. ridgwayi*) occurs in Arizona. Although in New England and elsewhere called "quail" and in the Middle and Southern States very generally "partridge," neither of these names is, properly speaking, correct. The "bob-white" of the farmer's boy is a far more characteristic and appropriate name. Like related species it is gregarious, but the coveys consist of members of one family—a pair of old birds and their numerous progeny of one or two broods—which remain in company until the next pairing season. They live where thickets, woodland borders or fence rows offer suitable cover. Throughout most of the year they feed

upon berries, seeds and mast and frequent grain-fields after harvest to glean the fallen seeds. Occasionally they attack fields of buckwheat, of which they are very fond, but the slight damage thus done is repaid manyfold in the destruction of grasshoppers and other insects in the late summer and autumn. Most of their life is spent on the ground, on which they scratch like hens. When whistling or sometimes when alarmed they will perch upon trees or fences, but usually run to a cover, where they remain perfectly motionless or spring suddenly into the air with a loud whirr and fly swiftly straight away to a thicket. At night they commonly huddle together in a close bunch with heads outward in the concealment of a bush, but may occasionally roost on trees. The call is a clear loud whistle of two or three notes, variously interpreted as "ah, bob-white," "buckwheat" and "no buckwheat" or "more wet" and "no more wet."

Being non-migratory, the bob-white is frequently exposed to privation during the winter. During a heavy snow-storm the members of a covey will often huddle together to keep warm and allow themselves to become completely covered and should a crust form on the surface many will sometimes perish miserably. In April and May they construct simple nests of coarse grass stems, usually arched over at the top, in a depression on the ground under the shelter of a bush or tuft of grass. The many eggs are pure white and top-shaped and arranged with the pointed ends downward. The young run immediately after hatching and are wonderfully interesting and pretty creatures with a marvelous skill for concealing themselves when alarmed. Sometimes a second brood is raised in August. When this is the case the male takes sole charge of the first until the second is hatched, when both parents join the combined broods; thus are formed the largest coveys.

The bob-white combines all of those qualities which a sportsman seeks in an ideal game bird and it is, without question, the most sought and most generally appreciated by gunners of any game bird in this country. Every condition unites to make the sport exhilarating and healthful, to test the skill of the sportsman and to please his appetite at the close of his labors. In most States this perfect game bird is now rigidly protected by laws prohibiting snaring, netting and trapping, by the enactment of a close season covering the breeding period and continuing until the young birds are strong of wing, or by other measures designed to meet local conditions or abuses. In several States at present the shooting of quail is prohibited for five or more years. Although the bird is so prolific it has numerous natural enemies, especially hawks, weasels, skunks, cats, etc., which check its increase. When to this natural loss is added the enormous number annually sacrificed to the deservedly popular sport of quail-shooting, the necessity of legal protection becomes manifest. The nature and method of the sport differs so much with the varied actions of the birds due to season, locality, character of ground, etc., and to the local and personal idiosyncrasies of gunners, that the reader must be referred to some of the numerous sporting books for details. The general method is to hunt singly or in couples,

with one or two dogs, which quarter the ground under the guidance of signs and whistled signals from the sportsman. When the birds flush they spring up suddenly and immediately attain full speed, which keeps the gunners always on the *qui vive*. Either pointers or setters may be used according to the character of the ground and the personal preference of the sportsman. By many the Llewellyn setter is considered to be the most perfect dog for rapid quartering of the ground and general adaptation to this class of sport. As to guns, tastes differ, but a hammerless arm of moderate weight, long range and 12 or 14 bore has the preference of experts.

These birds have been successfully bred in captivity, as is explained in the article **GAME-BREEDING**.

Consult books mentioned under **BIRDS** and publications of the United States Biological Survey, especially Bulletin 21, Judd, 'Bob-white and Other Quails . . . in their Economic Relations' (Washington 1905).

QUAIN, kwān, Jones, English physician: b. Mallow, Ireland, 1796; d. London, 27 Jan. 1865. He studied medicine at Dublin and Paris and was professor of anatomy and physiology at London University 1831-36. He was the author of Quinn's 'Elements of Anatomy' (1828; 10th ed., 1890), and published also a series of 'Anatomical Plates' (1858) and a translation of Martinet's 'Pathology' (1835).

QUAIN, Richard, English anatomist, brother of J. Quain (q.v.): b. Fermoy, Ireland, July 1800; d. London, 14 Sept. 1887. He was appointed professor of anatomy and clinical surgery in University College, London, in 1837, and was elected president of the Royal College of Surgeons in 1868. Among his works are 'Anatomy of Arteries,' with folio plates (1845); 'Diseases of the Rectum' (1854); 'Observations on Medical Education' (1865); 'Some Defects of Medical Education' (1870). He bequeathed nearly \$375,000 to University College, London, for the "education in modern languages (especially English) and in natural science."

QUAIN, Sir Richard, English physician, cousin of J. and R. Quain (q.v.): b. Mallow, County Cork, 30 Oct. 1816; d. London, 13 March 1898. He studied medicine in University College, London, whence he was graduated in 1842. He was elected a member of the Royal College of Physicians in 1846; in 1871 was chosen a Fellow of the Royal Society and he was president of the General Medical Council from 1891 till his death. He was created a baronet in 1891. His practice in London was large and lucrative and besides publishing several medical treatises he edited a well-known 'Dictionary of Medicine' (1882; new ed., 1894).

QUAKER CITY, a popular nickname applied to Philadelphia, which was planned and colonized by William Penn and other members of the Society of Friends.

QUAKER HILL, Battle of, in the American Revolution, a notable battle fought 29 Aug. 1778. On the previous night, the 28th, the Americans on Rhode Island fell back toward Butts Hill at the northern end of the island. Contrary to Greene's advice the enemy was allowed to occupy Quaker and Turkey Hills. From

these hills the British assailed the Americans, but were repulsed and driven back to Turkey Hill. The hottest of the battle took place on the low ground between the hills. The American loss in killed and wounded was 206; that of the British 222.

QUAKER POET, The, a name often applied to John Greenleaf Whittier, and long before his day bestowed upon the English poet, Bernard Barton (q.v.).

QUAKERS. See **FRIENDS**, **RELIGIOUS SOCIETY OF**.

QUAKERTOWN, Pa., borough in Bucks County, 38 miles north of Philadelphia, on the Philadelphia and Reading and on the Quakertown and Delaware River railroads. It manufactures cigars, harness and stoves and has silk mills. Pop. 3,801.

QUALIFICATIONS FOR OFFICE. See **ELECTORAL QUALIFICATIONS**.

QUALIFICATIONS OF VOTERS. See **ELECTORAL QUALIFICATIONS**; **WOMAN SUFFRAGE**; **ELECTIONS**; **NATURALIZATION**; **VOTES**, **VOTERS**, **VOTING**.

QUALITY, in the language of logicians, is used to designate the nature of propositions as affirmative or negative: the proposition "gold is a yellow substance" is of affirmative quality; "gold is not easily fusible" is a proposition of negative quality. In metaphysics quality is either primary or secondary; primary qualities are those which are essential to the existence, or even the conception of the thing; secondary qualities are those not essential to such conception; whether primary or secondary, a quality is that which makes, or helps to make, anything such as it is. An essential quality is that which may not be separated from a substance or an individual without taking it out of its class. On the other hand an accidental quality may be detracted from a substance or individual without a change of classification.

QUANA, Parker, Comanche chief: b. about 1845; d. 1911; the most influential leader among the three confederated tribes of Kiowa, Comanche and Apache in southwestern Oklahoma. He was the son of Nokoni, the principal chief of the Comanche, and Cynthia Parker, a white captive. Quana became prominent in 1874, when he acted as leader of the band of 700 picked warriors from the confederated tribes in an attack on the South Canadian River fort, Adobe Walls. He was active in the Indian uprising of the following year and was the last to surrender when peace was ultimately made. His superior intelligence, however, induced him to acquire white habits and customs, and after some time spent in Texas, he became thoroughly convinced of the benefits of civilized life. On his return to his tribe he endeavored to persuade them to adopt his views. In 1882 he proposed leasing the surplus pasture lands of the reservation, a measure which increased the income of the tribes by \$100,000 yearly. In 1888 he was appointed a judge of the Indian Court, and in 1892 was the first signer of the treaty which opened the reservation lands to settlers in 1901. Parker Quana did much to civilize the Indian tribes under his leadership. He was himself a man of keen intelligence and a linguist, speaking several Indian dialects and English and Spanish. He recognized that the

only salvation for the Indian was to be found in education and the adoption of the ways of civilization. He established schools for the Indians and all his children were well educated. Two at least of his daughters married white men. After the division of the Indian lands, Parker Quana lived in a large modern house surrounded by a well-cultivated ranch. For considerably over a quarter of a century he was the most prominent member of the three allied tribes, Kiowa, Comanche and Apache, practically all of whose tribal business was in his hands. In this capacity he made several visits to Washington, where he always had the consideration of the government. He also traveled extensively throughout the United States and made a careful study of agricultural methods and of the ways of living among the whites, which he copied and taught to his people by example and precept. It was through his earnest and persistent efforts that the Indians of his tribes secured rights of citizenship.

QUANAH, Tex., city and county-seat of Hardeman County, 200 miles northwest of Dallas, on the Fort Worth and Denver City, the Saint Louis and San Francisco and the Quanah, Acme and Pacific railroads. Irrigation is carried on to a considerable extent in the vicinity, the crops being chiefly cotton, corn and wheat. Manufacturing includes flour, cement, cottonseed oil and cottonseed feed products. The town is growing in size. Pop. 3,127.

QUANTIFICATION OF THE PREDICATE, supplying to the predicate in a logical proposition a word, as "some," or "all," or "no," etc., to indicate whether the whole of it or only a part agrees with or differs from the subject. In the proposition "all metals are elements" the subject "metals" is quantified by the use of "all"; but the predicate is not quantified, and in form the proposition does not distinctly assert whether metals constitute the whole list of elements or not. But by inserting "some" before the predicate, "elements" is quantified — "all metals are some elements." It was assumed by Aristotle and was maintained by all logicians after him till Ploucquet and Lambert in the 18th century and Sir William Hamilton in the 19th, that the predicate of all affirmative propositions is "undistributed" (not taken in its universal comprehension), while the predicate of a negative proposition is always distributed. But after Sir William Hamilton had given notoriety to the doctrine of quantification, this was seen to be an error, through which an infinite number of affirmative propositions which are universal in both terms are excluded from the system of formal logic. Among the numerous changes in the theory of formal logic which follows from the adoption of the quantified predicate the most important are the reduction of the conversion of propositions from three species to one, reduction of all the general laws of categorical syllogisms to a single canon, and the abrogation of all the special laws of syllogism. But the doctrine of the quantification of the predicate has never been generally adopted in the exposition of formal logic, on the ground that there is no proposition that cannot be dealt with under the Aristotelian forms, and that quantification does not really simplify the theory of logic. At present both the old Aristotelian-formed logic

and the logic of quantification have been supplanted by the symbolic logic. See **LOGIC**, **SYMBOLIC**.

QUANTITY, in the language of *Mathematics*, is whatever can be measured: space, time, weight, number, force, etc., are quantities. Quantities are represented in mathematics by symbols, and these too are called quantities. In algebra quantities are distinguished as known and unknown, real and imaginary, constant and variable, rational and irrational. For the meaning of these terms, see **ALGEBRA**, **DEFINITIONS AND FUNDAMENTAL CONCEPTS**; **VARIABLE QUANTITIES**. A simple quantity is expressed by a single term, as a or b ; a compound quantity is one expressed by two or more terms connected by the sign of plus (+) or minus (—). Quantities having the plus sign prefixed are called positive or affirmative; those with the minus sign prefixed are called negative quantities. Similar quantities are such as consist of the same letters, and the same powers of the letters, as abc , $-2abc$, $+4abc$, etc. In *Logic*, quantity is the extent to which the predicate in a proposition is asserted of the subject: when the predicate is affirmed of the whole of the subject the proposition is a universal one, as in the example "all metals are elements"; but when the predicate is affirmed only of a part of the subject, as in "some metals are brittle," the proposition is called a particular one. See **OPPOSITION**. In *Grammar* and *Prosody*, quantity is the measure of a syllable, or the time in which it is pronounced. In *Music*, quantity is the relative duration of a tone.

QUANTRELL, William, American guerrilla: d. Kentucky, 1864. His depredations first became widely known when he raided Lawrence, Kan., destroying 185 buildings, killing 140 inhabitants and leaving the town completely devastated. His operations were then continued through western Missouri and eastern Kansas, but upon his extending his ravages to Kentucky in 1864 he was outwitted and killed.

QUANZA, a river of Africa. See **KWANZA**.

QUAPAW (kw'ä-pä) **INDIANS**. See **SIUAN**.

QUAQUAVERSAL FOLD. See **FOLDS**.

QUARANTINE, a stated period (formerly 40 days) during which a ship coming from a port suspected of contagion, or having a contagious sickness on board, is forbidden intercourse with the place at which it arrives. Quarantine was first introduced at Venice in the 14th century, is now required in almost every important country except Great Britain. In the United States quarantine enactments were passed by the colonial legislatures and afterward for many years by the States. The first national quarantine act was passed 23 Feb. 1799, requiring Federal officers to aid in the execution of State or municipal quarantine regulations. On 29 April 1878, a national quarantine act was passed. On 3 March 1883, \$100,000 was appropriated for maintaining quarantine points along the coast. On 1 Sept. 1892, owing to the presence of cholera, President Harrison proclaimed a 20 days' quarantine of New York. By law it is made a misdemeanor punishable by fine or imprisonment, or both, for the master, pilot or owner of any vessel entering a port of

the United States in violation of the act, or regulations framed under it. During the period of quarantine, all the goods, clothing, etc., that might be supposed capable of retaining infection are subjected to a process of disinfection, which is a most important part of the quarantine system.

From 7 Nov. 1896, the system of quarantine ceased to exist in Great Britain, so far as regards the British Islands. The Quarantine Act of 1825 required that quarantine should be imposed on all vessels coming to the British Islands from places from which "the plague or other infectious disease or distemper highly dangerous to the health of his Majesty's subjects" might be brought; but in recent years this act has applied only to the plague and yellow fever, and has not often been used. Vessels arriving from infected places or carrying goods, etc., from such places, were required to be kept at some safe distance from the shore and from other ships—all their passengers and crew being detained on board—until all danger of spreading infection was considered to have passed. Healthy persons were thus exposed to the risk of taking any disease there might be on the ship.

In some places quarantine establishments were maintained for receiving persons from suspected vessels, but most of these were long since abolished, and latterly the only receiving ships were some old hulks at the Motherbank in the Solent. These were maintained by the Privy Council, on whom devolved the administration of the Quarantine Acts. Orders in Council prescribed the system of quarantine. By the Public Health Act of 1875, the defense of the country against cholera was placed in the hands of the Local Government Board, and regulations were issued by that board for the purpose. Instead of quarantining the entire crew of an infected or suspected vessel, the method adopted consisted in the medical inspection of the persons on board, and the separation and detention of those who were suffering from cholera or who were suspected of being infected. All others were permitted to leave the ship, but were traced and watched by the local authorities. Infected articles on board were to be disinfected or destroyed.

Quarantine has long been considered ineffective against the introduction of disease, besides being a source of much danger to those who were compulsorily detained under the system. The sanitary ideas of our day favor the less showy but safer methods long used in England in case of cholera.

In the United States under the law of 28 March 1890, known as the Interstate Quarantine Act, the supervising surgeon-general of the Marine Hospital Service is charged with preparing the rules and regulations, under direction of the Secretary of the Treasury, necessary to prevent the introduction of certain contagious diseases from one State to another, and he has also supervision of the medical inspection of alien immigrants, which under the law of 3 March 1891 is conducted by the medical officers of the Marine Hospital Service. Under the Act of 15 Feb. 1893, he is charged with the framing of regulations for the prevention of the introduction of contagious diseases and the prevention of their spread, and he is also charged with

the conduct of the quarantine service of the United States. He has the direction of laboratories established to investigate the cause of contagious diseases, and publishes each week, under the title of 'Public Health Reports,' sanitary reports received from all parts of the United States and (through the State Department) from all foreign countries. Consult 'Quarantine in the Maritime Cities of the United States,' New York Acad. of Med. (1913).

QUARITCH, kwär'ich, Bernard, English bookseller: b. Worbis, Prussian Saxony, 23 April 1819; d. Hampstead, Middlesex, 17 Dec. 1899. In 1839-42 he was employed in a publishing house in Berlin, and in 1846 established himself in London. He was naturalized as a British subject in 1847, and in that year issued his first book catalogue, a single leaf. In 1848 he began issuing a monthly catalogue, which in 1854-64 was printed as a regular periodical under the title 'The Museum.' His business increased rapidly and he became known as an authority on rare and valuable books of all classes. For 30 years he practically controlled the rare book market, attending in person or by proxy every important book auction in England and America. His catalogues are remarkable productions, the first large one being published under the title 'Bibliotheca Xylographica, Typographica et Palæographica' (1873) and afterward reissued from time to time with valuable additions, the last complete catalogue being the 'General Catalogue of Old Books and Manuscripts' (1887-88, index 1892, 7 vols.) and increased by supplements in 1894 and 1897.

QUARLES, kwär'lz, Francis, English poet: b. near Romford, Essex, 1592; d. London, 8 Sept. 1644. He was educated at Cambridge and before 1629 went to Dublin as private secretary to Archbishop Ussher. In 1639 he was appointed chronologer to the city of London and at the opening of the civil wars wrote a work entitled 'The Loyal Convert.' Of the works of Quarles, in prose and verse, the most celebrated is his 'Divine Emblems,' a set of designs illustrated by verses. A great part of them are borrowed from the 'Emblems' of Hermanus Hugo, but the verses are his own. His 'Enchiridion of Meditations' (1641) is a collection of brief essays and aphorisms, in vigorous and occasionally eloquent language.

QUARRYING. Although there are at this time in the United States about 3,000 quarries in operation, with an annual product valued at above \$75,000,000, the quarrying industry has not kept pace with modern tendency and progress toward cheaper production. In building operations revolutionary changes have come about in the last few years in the erection of steel buildings and the manufacture of terra cotta and clay products, while quarrying has been, generally speaking, stationary. The natural result of this has been a large increase in the use of the cheaper substitute materials for general bridge and building work, where the natural preference would have been for stone as an ideal and more permanent material, but for its prohibitive cost. As the rapid increase in the use of these other building materials is the direct result of the use of modern methods and machinery to the elimination of hand labor

in the greatest degree, it follows that in this direction also lies the continued prosperity of the stone business. As a compromise between the minute subdivisions devised by scientists and the extremely general and often erroneous classification of quarrymen, the following division may be adopted for quarrying operations:

Limestones and Dolomites.—The sedimentary and bedded rocks, composed essentially of lime carbonate, or the mixed carbonates of lime and magnesia, the latter receiving the specific title of dolomite. Such have been found to pass into each other by insensible gradations, certain quarries producing at the same time material which, if classed on purely chemical grounds, would be relegated to both divisions. Limestones may also carry a considerable percentage of quartz, when they are called silicious limestones. When clayey, they are called argillaceous limestones.

Marble.—Including stones identical in composition with those noted under limestones and dolomites, but which through crystallization and other changes, mainly physical, have come to possess properties rendering them desirable for high-grade building or ornamental work. The marbles of New York, recently brought to light by The Adirondack Lumber and Mineral Corporation, for instance, are largely limestone, while those in Massachusetts, Berkshire County, are largely dolomite. With the marbles are also included a small series of serpentine rocks, which are likewise utilized for decorative purposes.

Sandstones and Quartzites.—Rocks composed essentially of sands cemented together with silica or with silica and iron oxide, being made over, as it were, from the detritus of pre-existing rocks. Those classed as *quartzites* are sandstones which have been rendered more or less crystalline through the deposition of silica between the original sand particles, as in the case with the *jasper* of Sioux Falls, South Dakota, or the Potsdam sandstone of Saint Lawrence County, New York. The tuffs and other volcanic fragmental rocks and the blue-stones are also here included.

Silica Sand.—Silica or silicious sand includes not only sand suitable for the manufacture of glass, but also a large quantity designated as engine and furnace sand. It exists in several States as a sandstone, requiring crushing and screening; as a stone that readily disintegrates when exposed to the action of the elements and needs only washing or burning to reduce the amount of organic matter and other impurities. On account of their use in industry as sand, they are discussed under that title.

Siliceous Crystalline Rocks.—Here are included the true granites and syenites, together with trappean rocks, such as are often designated as black granites; the gneisses or so-called striped or bastard granites; the mica schists; and melaphyre, basalt, andesite, syenite, clæolite, diabase, gabbro, norite, lisparite, diorite and other volcanic rocks.

Slate.—Including argillaceous rocks, which, through the process of shearing and incidental chemical activity, have undergone a partial metamorphism, resulting in the development of a pronounced tendency to split along certain planes, which may or may not be parallel with the original bedding, into thin sheets suitable

for roofing purposes. It is necessarily a consequence that such are restricted to the regions of pronounced earth movements, such as have resulted in the formation of mountain ranges.

The possible resources of the various States of the Union are as follows:

STATE OR TERRITORY	Present and prospective resources
Alabama.....	Granite, Limestone, Marble, Sandstone, Slate.
Arizona.....	Dolomite, Granite, Onyx, Marble, Sandstone, Trappean Rocks, Volcanic Rocks and Tuffs.
Arkansas.....	Elæolite, Syenite, Granite, Limestone, Marble, Sandstone, Slate.
California.....	Granite, Limestone, Marble, Sandstone, Slate, Trappean Rocks, Verd-Antique Marble, Volcanic Rocks and Tuffs.
Colorado.....	Granite, Limestone, Marble, Quartzite, Sandstone, Trappean Rocks, Volcanic Rocks and Tuffs.
Connecticut.....	Diabase, Gneiss, Granite, Limestone, Marble, Sandstone, Verd-Antique Marble.
Delaware.....	Gabbro, Gneiss, Limestone, Quartzite, Serpentine.
Florida.....	Limestone (shell and oolitic).
Georgia.....	Gneiss, Granite, Limestone, Marble, Sandstone, Slate, Verd-Antique Marble.
Idaho.....	Dolomite, Granite, Limestone, Marble, Sandstone, Trappean Rocks, Volcanic Rocks and Tuffs.
Illinois.....	Dolomite, Limestone, Sandstone.
Indian Territory.....	Dolomite, Granite, Sandstone, Limestone.
Indiana.....	Dolomite, Limestone, Sandstone.
Iowa.....	Dolomite, Limestone, Sandstone.
Kansas.....	Dolomite, Limestone, Sandstone.
Kentucky.....	Dolomite, Limestone, Sandstone.
Louisiana.....	Limestone, Sandstone.
Maine.....	Gneiss, Granite, Limestone, Sandstone, Slate, Trappean Rocks, Verd-Antique Marble.
Maryland.....	Gneiss, Granite, Limestone, Marble, Sandstone, Slate, Verd-Antique Marble.
Massachusetts.....	Gneiss, Granite, Limestone, Marble, Sandstone, Slate, Trappean Rocks, Verd-Antique Marble.
Michigan.....	Dolomite, Gneiss, Granite, Limestone, Sandstone, Slate.
Minnesota.....	Dolomite, Gneiss, Granite, Limestone, Quartzite, Sandstone, Slate.
Mississippi.....	Limestone, Sandstone.
Missouri.....	Diabase, Dolomite, Granite, Limestone, Sandstone.
Montana.....	Dolomite, Gneiss, Granite, Limestone, Marble, Sandstone, Trappean Rocks, Volcanic Rocks and Tuffs.
Nebraska.....	Dolomite, Sandstone, Limestone.
Nevada.....	Dolomite, Granite, Limestone, Marble, Sandstone, Slate, Trappean Rocks, Volcanic Rocks and Tuffs.
New Hampshire.....	Gneiss, Granite, Limestone, Slate.
New Jersey.....	Diabase, Dolomite, Gneiss, Granite, Limestone, Marble, Sandstone, Slate.
New Mexico.....	Granite, Limestone, Marble, Sandstone, Trappean Rocks, Verd-Antique Marble, Volcanic Rocks and Tuffs.
New York.....	Dolomite, Gneiss, Granite, Limestone, Marble, Norite, Sandstone, Slate, Trappean Rocks, Verd-Antique Marble.
North Carolina.....	Dolomite, Gneiss, Granite, Limestone, Marble, Sandstone, Serpentine, Slate, Trappean Rocks.
North Dakota.....	Dolomite, Sandstone, Limestone.
Ohio.....	Dolomite, Sandstone, Limestone.
Oklahoma.....	Dolomite, Sandstone, Limestone.
Oregon.....	Dolomite, Granite, Limestone, Sandstone, Trappean Rocks, Volcanic Rocks and Tuffs.
Pennsylvania.....	Diabase, Dolomite, Gneiss, Granite, Limestone, Marble, Sandstone, Slate, Serpentine.
Rhode Island.....	Dolomite, Gneiss, Granite, Limestone.
South Carolina.....	Gneiss, Granite, Limestone.
South Dakota.....	Limestone, Quartzite, Sandstone.
Tennessee.....	Granite, Limestone, Marble, Sandstone, Slate.

STATE OR TERRITORY	Present and prospective resources
Texas.....	Granite, Limestone, Marble, Sandstone, Slate, Trappean Rocks, Volcanic Rocks and Tuffs.
Utah.....	Granite, Limestone, Marble, Onyx, Marble, Sandstone, Trappean Rocks, Volcanic Rocks and Tuffs.
Vermont.....	Dolomite, Gneiss, Granite, Limestone, Marble, Slate, Verd-Antique Marble.
Virginia.....	Diabase, Dolomite, Gneiss, Granite, Limestone, Marble, Sandstone, Slate.
Washington.....	Granite, Limestone, Marble, Sandstone, Trappean Rocks, Verd-Antique Marble, Volcanic Rocks and Tuffs.
West Virginia.....	Calcareous Tufa, Limestone, Sandstone, Travertine.
Wisconsin.....	Dolomite, Gneiss, Granite, Limestone, Sandstone.
Wyoming.....	Granite, Limestone, Marble, Sandstone, Trappean Rocks, Volcanic Rocks and Tuffs.

In the earlier days of the stone industry hand methods were employed almost exclusively in the work of quarrying and dressing. The past 25 years has, however, witnessed the introduction of machinery and consequent changes. The old method of drilling and blasting, formerly applied to all classes of rocks, is now done away with, excepting in the very hardest and toughest of materials, or where, in the case of granite and trappean rocks, the material is to be utilized only for roads. Even where drilling and blasting are now resorted to, it is the custom to drill a series of holes on the line along which it is desired the stone shall break; these holes are then charged somewhat lightly with a slow-burning black powder and fired simultaneously. In this way the force of the explosion is delivered along a considerable surface and the danger of shattering the material through the sudden jar is reduced to a minimum. This process is at present largely limited to granite rocks which are too hard to be quarried by means of channeling machines.

Plug and Feather Work.—In quarries where good breaks require that the splitting strain be exerted well down in the ledge, experience has shown that the best method for getting out the material is usually the *plug and feather* system, in which a series of holes from one and one-quarter to two inches in diameter and of a depth from two-thirds to the full thickness of the sheet are drilled at intervals depending upon the character of the stone and its manner of cleavage. Two feathers—flat pieces of steel rounded on one side to fit the curve of the drill hole—are placed at the sides of the hole and the long-tapered wedge-shaped plug driven down between them. The material splits away in fairly regular blocks which must be otherwise cut to size by hand. The plug and feather method is still extensively in use for splitting large blocks of granite and marble. Holes three inches deep and five-eighths inch in diameter will serve for splitting blocks three feet deep and five-inch holes three-quarter inch in diameter for six-foot blocks. For marble and sandstone the holes have to be slightly deeper. In soft material such as sandstone, a drill mounted on the usual tripod finds frequent use, and this is far superior to hand methods, still in certain classes of work a drill mounted on a quarry bar will do much more and better work.

The advantages of the quarry bar are that all the holes are drilled to double length, intermediate ones being shallow. The lower half of the deep holes is drilled with a smaller drill bit so as to alternate the plug strain top and bottom and control the break by skillful sledging. In some instances compressed air at a pressure of 70 to 100 pounds is piped into the drill holes to extend a crack already started.

The wedges of the short hole tend to split along the top and those of the long hole split along the bottom, thus distributing the pressure and tending to split the stone in a clean, smooth plane and largely avoiding any tendency to run off. This distribution of splitting strains is to be worked out by experience in the peculiarities of the different ledges. The wedges or plugs need not in all cases be of a length equal to the depth of the holes. In some marble quarries, plug holes only five-eighths inch in diameter are put clear through the blocks, sometimes 10 feet deep, to weaken the line and ensure a straight break, the plugs, however, being shorter. This operation is much simplified by the use of the hammer-drill actuated by steam or compressed air.

Broaching.—In granite and other hard stones holes must be placed closer together and, as a rule, splitting across the grain is abandoned in favor of *broaching*. In this system, a series of holes is drilled, usually about three inches apart from centre to centre, leaving walls of three-quarters inch to two inches between, depending upon the hardness of the rock, and a flat bit or "broach" is substituted for the regular steel. This has a face about three inches by three-quarters inch thick and is forged with a blunt end to crush this wall or web between the holes. Drills used for broaching must have the release which is a simple device to throw the pawls out of action and allow the drill to work without rotating. Broach channeling is the best and cheapest method of cutting out key blocks, lumps, and making wall cuts, etc., in granite quarries, where the rock is too hard to be cut advantageously with the regular channeling machine.

Channeling Machines.—Channeling machines are utilized in the case of rocks of the nature of marble, limestone and the softer sandstone, since they would be liable to injury through blasting and since it is desired to remove the materials from the quarry bed with a minimum amount of waste and in such size and shape that they may be cut into suitable dimensions. The Wardwell channeling machine, the earliest in use, has given way to the direct-acting stone channeling machine, the design of which was based upon the conviction that the same principles which had made the Ingersoll-Sergeant drill famous would, properly applied, give the best results in cutting a channel. It was believed that the direct-acting machine possessed points of decided advantage over the slow, cumbersome diamond and lever types of rock-cutting machinery of that day. Although certain shortcomings appeared in the first models, still it is an interesting fact that some of these first machines are in service to-day after more than 15 years of continuous use and are still doing good work. The success of these pioneer types demonstrated beyond question the merit of the direct-acting principle

now everywhere conceded as the correct one and it remained only to develop to the utmost the details of mechanical construction.

This machine is primarily suited for the heaviest work and the deepest cuts, in open quarries of limestone, sandstone, slate and other materials, where the output is in dimension stone. In this service it has found its greatest field in making the long, deep, longitudinal cuts which are preliminary to further breaking by the plug and feather method. It has found another valuable field of application in certain classes of heavy contracting work, such as rock excavation for canals and reservoirs.

The channeling machine is mounted on a self-propelling carriage or truck which runs on a track from 10 to 30 feet in length. If it has but one cylinder drill it is called a simplex machine; if two, a duplex machine. The stroke is about 10 inches and 250 blows are delivered per minute. The bits are usually used in gangs of three or five, set at varying angles, if the stone is uniform in texture. If uneven a single bit is used. In the usual quarrying operations the stone is channeled on two sides of a rectangle and then split off by wedges. In some instances it is channeled on three sides and also undercut at the bottom by a horizontal channeler called a "gadder." The average cut with these channeling machines is from 8 to 16 feet in depth, depending upon the nature of the stone. The gauge or width of the cut will depend upon the final depth sought. It may be from one and one-half to four inches at the start, reducing to a width of one and one-eighth inches with the last steels. The length of the channel is limited only by the length of track which can be used. Cutting speeds vary with the quality of rock and the handling of the machine. There are cases on record where the machine channeled faces aggregating 700 square feet in 10 hours in oolitic limestone, during part of which time over 100 square feet per hour was cut. In Ohio sandstone of medium hardness, 260, 280 and 300 square feet per day of 10 hours have been channeled and these rates are being maintained as an average by the month. The average cost in this case runs from two and one-half cents to three and one-half cents per square foot cut. When channeling is done on two sides of a block the bulk of stone taken out is about three and one-third cubic feet for each square foot of face channeled. Where the machine is used on three sides, the average product is two and one-half cubic feet per square foot of channeling. The extra cost of machine work is soon recouped, as in blasting out rough rock fully 20 per cent of the bulk is lost, being outside of the dimensions, and hence not paid for.

Helicoidal Saws.—Experiments with the so-called helicoidal saw for quarrying the softer rocks, as limestone and marble, have met with considerable success in the larger limestone quarries of the Middle West. The large amount of labor necessary for putting the saw in position and the waste involved in cutting out the corners in which the pulleys are run are weighty disadvantages, but where long cuts can be made—30 to 100 feet, this "saw" is very profitable. The "saw" consists of a three-strand twisted iron-wire rope, generally one-fourth of an inch in diameter, running over

sliding pulleys and fed continually with abrasive material such as sand or grains of chilled iron. It is necessary in working on bedrock to sink well holes for the 20-inch pulleys on which the saw runs. It is more commonly used for making vertical cuts. With a new thin model of pulley wheels the use of this saw is increasing.

After the stone is removed from the quarry bed it is worked into the desired shape and size by a process dependent largely upon the hardness of the stone. Formerly a block after being reduced to an approximately rectangular form by means of hand *plug and feather* splitting was still further reduced by pitching tools, followed when necessary by such implements as the point, ax, peak-hammer and bush-hammer. Pneumatic tools are gradually replacing these hand implements. Pneumatic surfacing machines, lathes and planers are now in use at the larger quarries. Indeed, the production of cylindrical columns by the old hand method has been almost entirely superseded by the use of lathes similar to those used in turning metals. Except on the harder stone, like granite and quartzite, saws are extensively used for dividing up material into rectangular masses and slabs where smooth, even surfaces are desired.

Electricity in Quarrying.—The quarrying industry to-day constitutes an important field for the application of electric current, and the subject has become so important as to create a literature and a technology of its own, for many of the problems involved are such as do not arise in connection with other work. The flexibility of electric circuits and the general adaptability of electric power have led to a wide range of applications, some of which are still in the experimental stage. Motors and other necessary equipment have been designed for special requirements. Beginning with a small direct current station and leading up to a complete high tension transmission and converting system, the use of electricity in mining and quarrying is very similar to its application to street railway work. Special motors for the equipment of mine locomotives have been designed to meet the peculiar conditions confronted in mining and quarry work. A recent application is that of the gathering locomotive which is to a great extent replacing animal haulage completely. This locomotive is equipped with a reel and cable, supplying power to it when gathering cars from rooms where no trolley is installed and where wooden rails are used. Standard motors are applicable to and are largely used on hoists, ventilating fans and drainage pumps.

The transmission of power over long distances by polyphase alternating current is one of the most notable and important developments in electricity. It has been a chief factor in the marvelous development of the Far West. Much of the progress in the country west of the Rockies is directly traceable to the use of electricity which, in many cases, generated at a distant waterfall, is transmitted to commercial centres where the power can be used as desired. The development of the gasoline engine and its adaptation to the air compressor provide the quarryman with a cheap and effective power even in isolated locations. The success of a

quarry, however, must always depend on facilities for getting the product to a market.

In a typical quarrying operation 100 men were formerly required to produce 5,000 tons of marble; now, since scrapping most of the plant and substituting modern machinery, 10 men produce 6,000 tons in the same time. The argument has been presented that mechanical methods cannot be used to the same advantage in quarrying as in the case of general manufacturing. To some extent this is true, depending upon the class of quarrying; for instance, in quarries producing rough rubble without regard to size or dimensions the mechanical features are confined to drilling, blasting and suitable hoisting apparatus and perhaps pumping or crushing, with the occasional use of steam shovels. There can be no question as to the economy of machine drilling over hand drilling, and the harder the material and the more difficult to drill by hand the greater is the advantage of machine drilling.

Successful quarries are those which closely approach the ideal of eliminating hand labor and, as in other profitable operations, are the result of heavy investments in all the machinery which can be used up to that point where additional apparatus will not reduce the waste. The modern methods of channeling, plug and feather work, power wedge hole cutters and the use of compressed air, very nearly reach this point, as it calls for few machine operators, a few men to bar out the stone so loosened and a gang of derrick men to place it on the cars for shipment in that attractive form best calculated to hold and expand the market at the highest trade price for the product. In most quarries the operating period is limited by the comparative shortness of the working season, and therein lies another advantage of machinery. Again, the smaller the force the more easily it is controlled and the better the opportunity for sifting the men down to a picked gang of machine runners, men who, at a slight addition over the prevailing rate of wages, will not only do very much more work, but will come nearer to the production of a perfect output without waste.

Production.—The United States Geological Survey reported for the calendar year 1916 the number of active quarries in the country at 3,036, and the value of their combined production at \$79,041,699. The State of Pennsylvania led in the number of active quarries, 516, and in the value of the product, \$11,021,655 — nearly 14 per cent of the total for the entire United States. It may be noted in passing that more than 60 per cent of this total represented limestone quarried for flux used in the iron industry. Among the other stone-producing States Ohio ranked next, with an output valued at \$6,611,266; Vermont third, with \$5,691,420; and New York fourth, with \$5,342,954.

As classified by the variety of stone produced the value stood: limestone, \$41,319,871; granite, \$17,418,582; trappean or basaltic rock, \$7,666,297; marble, \$7,033,171; sandstone, \$5,603,778.

As classified by the uses in which it was employed the 1916 output of the quarries shows values as follows:

Building Stone, rough and dressed, \$15,001,390, of which \$4,744,606 was in marble for both exterior and interior purposes; \$4,570,703 in limestone; \$4,305,517 in granite, and \$1,316,287 in sandstone.

Monumental Stone, rough and dressed, \$7,031,536, of which \$4,952,125 was in granite and \$2,079,410 in marble.

Paving Stone, \$2,692,605, of which \$2,293,486 was granite and \$327,264 in sandstone.

Curbing Stone, \$1,611,001, of which \$828,761 was in granite and \$702,902 in sandstone.

Flagging, \$409,665, of which \$389,859 was in sandstone.

Crushed Stone reached a quantity production of 48,075,581 tons, valued at \$29,462,952. Of this value limestone represented \$17,715,834; trappean rock, \$6,539,008; granite, \$3,543,416, and sandstone, \$1,664,694. The largest value of crushed stone consumed in any one particular use was \$12,419,667 for road metal, at an average price of 63 cents per ton. Concrete making absorbed a value of \$11,869,844, at an average price of 67 cents per ton. Railroad ballast represented a value of \$5,173,441, at an average price of 49 cents per ton.

Crushed limestone for furnace flux, not included in the above summary, amounted to 23,603,508 tons, valued at \$13,936,882, an average of 59 cents per ton.

The quarrying of limestone was carried on quite generally throughout the United States in 1916, Pennsylvania and Ohio showing the greatest activity, with values, respectively, of \$8,167,639 and \$5,337,085. Other States which contributed very largely to the grand total were Indiana, with a value of \$4,657,813; Illinois, \$3,362,751; New York, \$3,035,786; Michigan, \$2,389,763, and Missouri, \$1,990,419. In addition to these, Kentucky, Virginia, West Virginia and Wisconsin each showed an output in value above \$1,000,000. These 11 States produced nearly 80 per cent of the entire 1916 limestone production.

Although 30 States shared in the total output of granite in 1916, the bulk of the production came from eight States. Vermont's value was \$2,500,579; that of Massachusetts, \$1,997,150, and that of North Carolina, \$1,798,087. In addition to these, California, Maine, Minnesota, New Hampshire and Wisconsin each contributed a value of above \$1,000,000.

Marble was quarried in 22 States, but nearly half of the total production was by Vermont — in value, \$3,062,743. Most of the remainder came from Tennessee (\$1,000,266) and Georgia (\$903,343).

Exports.—The export trade of the United States in products of its quarries is well nigh world wide. In 1916 the value of such exports was \$1,480,750, of which a value of \$693,723 (about 47 per cent) went to Canada. Great Britain appears in the record as the customer of next importance, with purchases amounting to \$169,672. Then follow in order Italy, \$93,843; Cuba, \$84,242; British East Indies, \$62,311; Argentina, \$42,194; France, \$34,908; Australia, \$21,753; Panama, \$21,086; British South Africa, \$20,730, and Brazil, \$17,365.

Imports for the same year amounted in value to \$959,367, of which sum \$723,411 represented marble and onyx (\$34,359), of which less than 20 per cent was manufactured. Most of the marble (\$640,805) came from Italy, and the remainder from Mexico and France, with a small quantity from Greece. Mexico and Greece supplied the onyx.

There exists in the stone industry the same tendency toward the concentration of capital and the formation of stock companies as in other branches of trade. This is due not altogether to the desire for combination with a view to controlling trade, but in part at least to a change which has taken place in the character of the industry. The installation of costly machinery and the fact that the quarries in many cases now contract not merely to furnish the stone, but to furnish it cut and ready for its definite position in the structure, even if they do not contract to set it in place as well, involve a larger capitalization and supply of available funds. Consult Gillette, H. P., 'Handbook of Rock Excavation' (New York 1916); Greenwell, A., and Elsdon, J. V., 'Practical Stone Quarrying' (New York 1913). See **BLASTING**; **BUILDING MATERIALS**; **MINES AND MINING**; **MINING AND MILLING MACHINERY**; **POWER TRANSMISSION**.

EDWARD S. FARROW,

Consulting Mining and Military Engineer.

QUART. See **WEIGHTS AND MEASURES**.

QUARTER. See **WEIGHTS AND MEASURES**.

QUARTER-CRACK. See **SANDCRACK**.

QUARTER DAYS, in England, the days which begin the four quarters of the year, namely: 25 March, or Lady-day; 24 June, or Midsummer-day; 29 September, or Michaelmas-day; and 25 December, or Christmas-day. In England and Ireland it is usually contracted between landlord and tenant that rent should be paid and that houses may be entered or left on these days. In Scotland there are two legal term days, Whit Sunday (15 May) and Martinmas (11 November). There are also two conventional terms, Candlemas (2 February) and Lammas (1 August), on which rents are frequently paid. In the United States, in law, quarter days are the 1st of January, April, July and October. In the relation between landlord and tenant in some of the States they are the 1st of May, August, November and February, respectively.

QUARTER DOLLAR, in American coinage a silver piece of the value of 25 cents. Its issue was first authorized (weight, 104 grains) by Congress in 1792, and its coinage was begun in 1796. It was reduced to 93 grains in 1853. This coin is legal tender to the amount of \$10. There were no issues of the quarter dollars during the years 1798 to 1803, inclusive, 1808 to 1815 inclusive, 1817, 1824, 1826 and 1830.

QUARTER SESSIONS. See **COURT**.

QUARTER-STAFF, an old English weapon formed of a stout pole of heavy wood, about six feet long, loaded with iron at both ends.

QUARTERING ACTS, acts of the British Parliament which did away with certain of the penalties of high treason as prescribed by law in ancient times. The offender, if a man, was drawn on a hurdle to the place of execution, there hanged by the neck till he was dead, the head severed from the body, the body disemboweled and divided into four quarters, and the head disposed of at the pleasure of the king. If the offender was a woman she was drawn to the place of execution and there burned alive.

By successive acts of the Parliament (30 Geo. III, ch. 48, and 54 Geo. III, ch. 146) the punishment of a female traitor was changed to hanging; and in the case of men, the Crown might change the sentence to beheading, or might remit it wholly. Under the Felony Act of 1870 hanging is made the one penalty of treason; but as the act 54 Geo. III, ch. 146 was not repealed, the offender, if a man, may by Crown warrant be beheaded.

QUARTERMASTER, (1) in military affairs, an officer who superintends the issue of stores, food and clothing, and arranges transportation for a regiment when necessary. In the United States army, where the quartermaster is also in charge of paying the men, only officers of the Quartermaster Corps (q.v.) are accorded this title. The officer of the line detailed in a regiment for the performance of similar functions is known as the regimental supply officer. (2) In nautical affairs, a petty officer who, besides having charge of the stowage of ballast and provisions, coiling of ropes, etc., attends to the steering of the ship. He is appointed by the captain.

QUARTERMASTER CORPS. In 1912 the Quartermaster Corps of the United States army was formed by the fusion of the old Quartermaster's, Subsistence and Pay Departments, all of which date back in some form or other to the first two decades of the 19th century. The resulting organization is commanded by the quartermaster-general, who ranks as a major general. The corps is subject to the general supervision of the Chief of Staff. It combines the functions of its predecessors, and takes care of all the business needs of the army which have nothing to do with munitions of war or the special supplies of the Corps of Engineers, the Signal Corps and the Medical Department. Among its duties is the provision of transport by steamboats, railroads and trains of wagons, trucks and pack animals. It furnishes the personnel of the service of supply in the zone of communications and at the front—teamsters, chauffeurs, packers, etc. It purchases stores, and distributes equipment and food, and establishes the necessary supply and commissary depots. It furnishes field bakeries to keep the troops supplied with bread. It disburses the funds necessary for the pay of the army. It contracts for all services necessary for the troops, and for the construction of such buildings as may be needed. In short, its activities are as varied as would be expected in a business enterprise of its magnitude. All officers of the Quartermaster Corps ranking as captain or over are detailed from the line. The establishment of the Quartermaster Corps is one major-general; two brigadier-generals; 21 colonels; 24 lieutenant-colonels; 68 majors; 180 captains; and such subordinate officers, non-commissioned officers and privates as the needs of the service may require. These are: pay clerks, ranking as second (or rarely first-lieutenants); field clerks, Quartermaster Corps; quartermaster sergeants, senior grade; quartermaster sergeants; sergeants, first class; sergeants, corporals, privates first class; and privates. In time of war, the Quartermaster Corps of the regular army may be supplemented by captains and majors from the Officers' Reserve Corps, and with non-commissioned officers and

privates from the Enlisted Reserve Corps. At present there are first and second lieutenants in the Quartermaster Corps, branch of the Officers' Reserve Corps, but this is not a permanent provision.

QUARTERMASTER-GENERAL, in the army of the United States, a staff-officer with rank of brigadier-general. He is chief officer in the Quartermaster Corps (q.v.). In England he is a staff officer, specially appointed for duties connected with quartering, encamping, embarking and moving troops. In both armies in the field he is responsible for the general direction of the railway, postal, signaling and telegraph services. In the United States army he has charge of the pay service also.

QUARTERMASTER-SERGEANT, in the United States army, a non-commissioned officer whose duty it is to assist the quartermaster. Formerly there were company quartermaster-sergeants, but their place is now taken by the company supply and mess sergeants. There are three regimental quartermaster-sergeants to each regiment, one to each battalion. The two highest grades of non-commissioned officers in the quartermaster corps are quartermaster-sergeants, first class, and quartermaster-sergeant, respectively. (See **QUARTERMASTER CORPS**). In England the quartermaster-sergeant is the senior sergeant in the quartermaster's department of a regiment. He ranks next the sergeant-major.

QUARTERN. See **WEIGHTS AND MEASURES**.

QUARTEROON. See **QUADROON**.

QUARTET, or **QUARTETTE** (Italian *quartetto* from *quarto*, a fourth), a musical composition for four voices or instruments, in which all the parts are *obbligati*, that is to say, each is indispensable to the just performance of the piece; no one part can be omitted without injuring the proper effect of the composition. Also four persons who sing or play together. Vocal quartets are generally accompanied by instruments to sustain the voices, but the most artistic effect is produced by their perfect rendition unaccompanied. An interchange of melody, whereby the parts become in turn principal and subordinate, without any interweaving of them, does not constitute a quartet (see **POLYPHONY**). Quartets for stringed instruments are generally arranged for two violins, a viola or tenor violin and a violoncello. Haydn was the originator of the modern instrumental quartet, and his contemporary emulators were Mozart, Beethoven, Gietry, Sammartini, Onslow, the two Rombergs and Ries. Among later masters of the quartet form are Schubert and Brahms. See **MUSIC**.

QUARTIER LATIN, kâr-tê-â lâ-tân. See **PARIS**.

QUARTLEY, kwârt'li. Arthur, American artist: b. Paris, 24 May 1839; d. New York, 24 May 1886. Coming to the United States in 1851, he studied in Baltimore and New York and was elected National Academician in 1886. His most important works are marines, and among them may be mentioned 'New York from North River'; 'Afternoon in August—Coast of Maine' (1878); 'Low Country on the North Shore of Long Island' (1881); and 'Off the Shoals.'

QUARTO (also written 4to), originally a sheet of paper twice folded, or a book made of a sheet folded twice, so as to have four leaves or eight pages to a sheet; now a book size, varying from about 15 × 11 inches (imperial quarto), to about 6½ × 9 inches. In loose usage, any volume of large pages.

QUARTODECIMANS, kwar-tô-dês'i-manz, the name given to those Christians in the early centuries who celebrated the Easter festival on the same day as the Jews celebrated the Passover, namely, the 14th day of the month Nisan. Most of the churches, both of the East and West, celebrated the Christian Passover always on the Sunday next succeeding the day observed by the Jews, never on 14th Nisan, even if that day was Sunday. The Council of Nice (325 A.D.) enjoined on all the faithful this rule; thereafter the Quartodecimans were held to be heretics.

QUARTZ, the name given the native oxide of silicon, SiO₂. It is a widely distributed mineral occurring not only in veins and segregated masses, but as a common constituent of igneous rocks. Detrital grains form sands, and when cemented, sandstones and quartzites. Owing to differences in color and texture and its use as a semi-precious stone, the names given varieties of quartz are many. All these varieties, however, are included in two classes, the plainly crystalline or vitreous, and the obscurely crystalline called crypto-crystalline. All varieties have about the same hardness, seven, that is, can scratch window glass, and nearly the same specific gravity, 2.6. Pure quartz is fusible only at high temperatures.

Quartz crystallizes in the rhombohedral system, generally as six-sided prisms usually terminated at each end by six-sided pyramids. Among the crystalline varieties of quartz are rock crystal, amethyst, smoky quartz, rose quartz, milky quartz, the mineral being colorless when pure, but ranging through various shades of yellow, red, brown, blue and green to black when impure. Colorless quartz, or rock crystal, is often cut into gem shapes and sold as Lake George diamonds, Brazil pebbles, etc. Perfectly clear crystals of larger size are highly prized in Japan when cut and polished as spheres. Recently developed uses of rock crystal are in the manufacture of fibres for suspending the minute magnets and mirrors used as galvanometers and in the manufacture of spectrum tubes and test tubes, the quartz being fused by the oxyhydrogen blowpipe. Quartz fibres are used for galvanometers because they show no torsion and the mirrors have no permanent set or deviation from the true position when at rest. Vessels made of fused quartz can be heated to a white heat and plunged into cold water without injury and on this account quartz tubes are used for studying the spectra gases at high temperatures.

Of the colored varieties of crystalline quartz amethyst is clear purple or bluish-violet, and is popular as a gem; rose quartz, which always occurs massive, is rose red or pink; yellow quartz, or citrine, is often called topaz by jewelers, but may be distinguished from true topaz by its inferior hardness; smoky quartz, called also cairngorm stone, varies in color from smoky yellow to brownish black; milky quartz, white, nearly opaque and often with a greasy lustre, is of common occurrence in veins; sagen-

itic quartz has inclusions of needle-like crystals of rutile, actinolite, asbestos (cat's-eye) or black tourmaline; sapphire quartz, indigo blue in color, is a rare variety. Many quartz crystals contain small cavities partly filled with liquids, generally water, also inclusions of carbonic acid, either liquid or gaseous. The cryptocrystalline varieties of quartz include chalcedony, and its varieties, carnelian, chrysoprase, prase, plasma, agate, onyx and sardonyx; also flint, hornstone, touchstone and jasper. Chalcedony has a wax-like lustre, is translucent or transparent, and its color varies from white through pale brown to dark brown or black, though it is occasionally blue; carnelian or sard, is a red or brownish-red chalcedony; chrysoprase an apple-green variety; prase, a dull darker green; plasma, a leek green or emerald green; bloodstone, a dark green chalcedony with small red spots, like drops of blood; agate, a chalcedony with delicate parallel bands of color, or irregularly clouded color effects, the colors being white, red, brown or even blue, while moss agate contains moss-like forms caused by oxide of manganese; in onyx the differently colored bands are straight and parallel; sardonyx is onyx containing bands of carnelian (sard); flint differs from chalcedony in being more opaque, having a slightly vitreous lustre, being generally gray or brown in color; it breaks with a sharp cutting edge; it was used by the early races of men for arrow heads, knives, etc.; hornstone resembles flint, but has a splintery fracture, and is often white; touchstone, known also as basanite or Lydian stone, a black hornstone or jasper, used for testing the purity of precious metals by rubbing them on it; jasper differs from the preceding varieties in being entirely opaque; it is often red, yellow or brown.

Common milky quartz is used for a variety of purposes. In metallurgical operations it is used as a flux in smelting iron and copper ores; when finely crushed it is used by porcelain manufacturers for making glazes, quartz sand and ground pure quartz are used in immense quantities for making glass. Another use is as an abrasive, either as sandpaper or as sand or a fine powder. In these forms it is used for dressing stone, wood and leather; while the powder, mixed with soap, forms a widely advertised cleansing compound. See MINERAL PRODUCTION OF THE UNITED STATES.

QUARTZ MONZONITE. An igneous rock resembling granite in general appearance but of mineral composition intermediate between syenite and diorite and with less quartz than granodiorite. Several of the well-known New England "granites" and the gray "granites" of Minnesota and California are mostly quartz monzonite or granodiorite.

QUARTZORITE. An igneous rock of granular structure, mostly of dark color and extensively quarried as a variety of granite. The chief feldspar is plagioclase with which occur free quartz, generally some orthoclase and some of the darker silicates such as biotite, hornblende and augite. It is closely related to granodiorite and quartz monzonite and is chemically similar to dacite which is supposed to be an effusive equivalent.

QUARTZ PORPHYRY, an igneous rock characterized by containing crystals of quartz and feldspar with sometimes biotite and more

rarely hornblende scattered through a ground mass that is glassy or contains fine crystals of quartz and feldspar. The name was formerly given to free Tertiary rhyolites and is still applied to rhyolites that have crystallized as dikes or laccolites rather than as surface flows, but these distinctions have little value. In general quartz porphyries differ from rhyolites simply in being denser. Quartz trachyte is a name given rhyolite by European geologists. Quartz porphyries are of quite common occurrence in the Western States and are of peculiar importance at Leadville, Colo. See RHYOLITE.

QUARTZITE, a rock of common occurrence in mountain ranges or when strata have been strongly folded. It is simply a metamorphosed sandstone, its hardness and rather crystalline character being due to the cement of crystalline quartz that surrounds the grains of the original sandstone. A sandstone containing clay becomes a quartzite containing mica, and thus quartzites grade into quartz-schists and mica-schists. In general quartzites resist weathering and thus form ledges. They differ greatly in color.

QUASI-CONTRACT. A quasi-contract—often called a constructive contract—is one founded solely on an obligation of law and not upon the intention or consent of the parties. Such contracts are imposed by law on the theory that they are dictated by reason and justice. Quasi-contracts are usually founded (1) on a record, as a judgment; (2) on a statutory, official or customary duty, as the obligation of a husband to pay for necessities supplied his wife; (3) on the doctrine that no one should be allowed to enrich himself unjustly at another's expense, as the liability to repay money paid by mistake of fact. A marked distinction between a quasi-contract and a true contract is that the latter is founded upon the consent of the parties thereto, whereas the former is founded on a legal obligation without any consent of the parties. As has been aptly said in the case of consensual contracts the agreement defines the duty, while in the case of quasi-contracts the duty defines the contract. Much real difficulty has been experienced in distinguishing between quasi-contracts and implied contracts, and some authorities hold that the distinction appears to be one of degree rather than of principle. There is authority for the statement that implied contracts embrace those in which there is an intent to contract or at any rate no intent not to contract. But in many cases of what are commonly called implied contracts the only intent apparent is in the imputation of knowledge that the law would impose a certain liability. This element is also present in many quasi-contracts. The test of definite intention not to contract, if applied to quasi-contracts, would exclude some from this classification, for example, an obligation to repay money paid by mistake of fact. Some authorities differentiate a quasi-contract from an implied contract by holding that the former is a mere legal fiction, a form imposed to adapt the case to a certain remedy, in which intention is disregarded, whereas in an implied contract the intent is ascertained and enforced and according to the common understanding of men the intention to contract is mutual. Quasi-

contracts are enforced by an action *ex contractu*.

By some earlier authorities the term "implied contracts," is made to include (1) contracts implied in fact and (2) quasi or constructive contracts. In the former the intention to contract may be inferred to exist by the acts of the parties, while in the latter there is an absence of all intent to contract. This classification is favored by some authorities today.

Among typical cases of quasi or constructive contracts, in addition to those mentioned above, are the following: cases of account stated, from which an obligation in law arises which will cause an action of *assumpsit* or debt to lie; cases in which one person has been obliged to pay money which another should have paid and which the former may recover from the latter in an action in *assumpsit* for money paid to his use; cases in which one person has received money which another should have received, for which an action will lie for money had and received; cases in which a person by wrongfully taking and retaining property is obligated by law to pay a reasonable price therefor; cases in which it is impossible for the plaintiff to complete a contract and in which he may recover for the value of what he has already performed; cases in which a defendant is in default under a contract which cannot be enforced because not in compliance with the Statute of Frauds and the plaintiff may recover for past performance; cases in which a person is under a legal obligation to pay money and another pays it without request for him, in which event the money may be recovered by an action at law. See CONTRACT.

EDWARD F. DONOVAN.

QUASIMODO, in the Roman calendar, a term applied to the first Sunday after Easter, from the opening words of the introit for that day, "*quasi modo geniti infantes*," as infants lately born. Also the name of a well-known character in Victor Hugo's novel 'Notre Dame de Paris.'

QUASS, kwäs, or **KVASS**, a Russian beverage, made by pouring warm water on rye or barley meal. It is sour and fermented.

QUASSIA, a genus of shrubs and trees of the order *Simarubaceae*. The best known species (*Q. amara*) is indigenous to tropical America, grows about 12 feet tall, bears large pinnate leaves with winged petioles and racemes of bright red blossoms. The wood is used for cabinet making and for furniture, since it is avoided by insects. It is excessively bitter, and was formerly in repute as a medicine and for augmenting the bitterness of ale, porter, beer and similar beverages. It is known also as bitterwood, by which name the wood of *Picræna excelsa* is likewise designated and used as a substitute for true quassia with which it vies in bitterness.

QUATERNARY, according to the United States Geological Survey, the last period of the Cenozoic era. It follows the Tertiary and includes the present. It is divided into the Pleistocene and Recent epochs, the former of which includes the great Ice Age, or Glacial Period. Some authorities disregard Quaternary and give Pleistocene and Recent the rank of periods. See GLACIAL PERIOD and PLEISTOCENE.

QUATERNIONS. Fundamental Principles.—A quaternion, or "set of four," is a quadrinomial of the form

$$w + xi + yj + zk,$$

in which w, x, y, z are numbers, and $1, i, j, k$ are four independent units, any three of which may be interpreted geometrically as a set of mutually perpendicular straight lines of unit length in three-dimensional space. The binary products xi, yj, zk are three mutually perpendicular line-segments of lengths x, y, z respectively; they are called *vectors*, while pure numbers, positive or negative, are called *scalars*.

The calculus of quaternions is an algebra in which the fundamental operations of addition, subtraction, multiplication and division, and the consequent operations of involution, evolution, etc., are employed, and whose elements (operators and operands) are quaternions. It is a multiple algebra, because a quaternionic symbol, as q , contains implicitly several independent quantities, and it is essentially geometric, because its operations, addition, multiplication, etc., may be interpreted as geometric transformations. For example, in illustration of the last statement, if q, r be two quaternions and be taken to represent two line-segments meeting at a point, their sum is the diagonal of the parallelogram of which q and r are two adjacent sides. This is known as geometric addition; its law is that of the parallelogram of forces. Multiplication by a quaternion is equivalent to an orthogonal transformation in four variables plus an expansion or a contraction. The geometrical construction of a quaternion product, however, needs the hypothesis of a four-dimensional space for its proper presentation.*

Vectors in particular are so defined as to obey the law of geometric addition. If several vectors represent the successive parts of a broken line in space, their sum is the line-segment joining the free ends of the broken line. In this process of addition the line-segments representing vectors may be transferred to any position in space, provided they remain parallel to their original directions, but the direction-sense must in every case be preserved.

In obedience to this interpretation a quaternion may always be written as the sum of a scalar and a three-dimensional vector; thus,

$$q = Sq + Vq,$$

wherein S and V are to be read "scalar of" and "vector of" respectively; for by the law of geometric addition $xi + yj + zk$ is itself a vector, while w , being a pure number, is by definition a scalar.

In the quaternion algebra the laws of association and distribution in the four fundamental operations, and the law of commutation in addition and subtraction, are assumed, or they may be derived from the geometrical definitions of the processes, but the commutative law in multiplication and division is rejected except for such quaternions as have vector parts that are numerical multiples of one another.

The laws of combination by multiplication are determined in the following manner: The

* See "Bulletin of the American Mathematical Society" (Vol. 11).

mutually perpendicular vectors xi, yj, zk are numerical multiples of the three independent units, i, j, k , and the combinatory laws for these units are derived from the assumptions

$$i^2 = j^2 = k^2 = -1, \quad ijk = -1,$$

from which are obtained, through multiplication by i, j, k in succession, the remaining binary products

$$jk = -kj = i, \quad ki = -ik = j, \quad ij = -ji = k.$$

From these laws it follows that the product of two quaternions is itself a quaternion. Thus q and r being given quaternions,

$$q = w + xi + yj + zk, \\ r = w' + x'i + y'j + z'k,$$

their product has the form

$$qr = W + Xi + Yj + Zk,$$

wherein

$$W = ww' - xx' - yy' - zz', \\ X = wx' + w'x + yz' - y'z, \\ Y = wy' + w'y + zx' - z'x, \\ Z = wz' + w'z + xy' - x'y.$$

If the order of the factors in this product be changed from qr to rq , the scalar part $ww' - xx' - yy' - zz'$ is unaltered, but the terms $yz' - y'z, zx' - z'x, xy' - x'y$ change their algebraic signs and, therefore, the vectors of qr and of rq are different. This result shows that in general quaternion multiplication does not obey the commutative law. In order that the above terms may not change sign (by a reversal of the order of the factors q, r) they must be separately zero, that is,

$$\frac{y}{y'} = \frac{z}{z'}, \quad \frac{z}{z'} = \frac{x}{x'}, \quad \frac{x}{x'} = \frac{y}{y'},$$

in other words, x', y', z' must be the same numerical multiples of x, y, z respectively. This makes $x'i + y'j + z'k$ a numerical multiple of $xi + yj + zk$, and it is the condition under which it is permissible to write $qr = rq$.

Division is interpreted by introducing the reciprocal, defined by the equation $qr = 1$, in which q and r are said to be reciprocal to one another, and, as in ordinary algebra, we write $r = q^{-1}$ and $q = r^{-1}$. This product obviously obeys the commutative law and also it has no vector part, so that

$$x' = nx, \quad y' = ny, \quad z' = nz, \quad [n = \text{a number}]$$

and

$$wnx = -w'x, \quad w' = -nw.$$

Hence the reciprocal of q must have the form

$$q^{-1} = \frac{1}{m}(w - xi - yj - zk),$$

where m is a number. By forming the product qq^{-1} , observing the laws $i^2 = j^2 = k^2 = -1, ij = -ji = k$, etc., it is easily shown that

$$m = w^2 + x^2 + y^2 + z^2.$$

This number is called the *norm* of q .

It is now evident that if $r = w' + x'i + y'j + z'k$ and $q = w + xi + yj + zk$, the quotient rq^{-1} is obtained by writing out the product

$$(w' + x'i + y'j + z'k) \cdot \frac{1}{m}(w - xi - yj - zk),$$

and that this quotient is a quaternion.

Hence, barring critical cases, such as division by zero, indeterminate forms, etc., the application of the four fundamental processes of algebra to quaternion symbols leads always to

determinate quaternion results. The quaternionic algebra is, therefore, a closed system and satisfies the definitions of a group with respect to addition, multiplication, subtraction or division. See GROUPS, THEORY OF.

The positive square root of the norm of q ($= +\sqrt{w^2 + x^2 + y^2 + z^2}$) is called its *tensor* and the quotient of q by tensor of q is called its *versor*, so that a quaternion is always the product of its tensor and versor. The symbolic form of this statement is

$$q = TqUq,$$

where T and U stand for tensor and versor respectively.

In the strictly symbolic notation the reciprocal of q has the form

$$q^{-1} = \frac{Sq - Vq}{T^2q},$$

and since $qq^{-1} = 1$ it follows that

$$S^2q - V^2q = T^2q.$$

The quaternions $Sq + Vq$ and $Sq - Vq$ are said to be *conjugates* of one another.

A vector has no scalar part, but it has a tensor factor and a versor (vector of unit length); and a scalar has no versor part, but it has a tensor, its positive numerical value, and a versor whose value is always ± 1 . It can readily be shown that the square of a

vector is -1 . Let the versor be $\frac{xi + yj + zk}{\sqrt{x^2 + y^2 + z^2}}$.

Its square will be

$$\frac{-x^2 + y^2 + z^2}{x^2 + y^2 + z^2} + i \left(\frac{yz - yz}{x^2 + y^2 + z^2} \right) \\ + j \left(\frac{ZX - ZX}{x^2 + y^2 + z^2} \right) + k \left(\frac{xy - xy}{x^2 + y^2 + z^2} \right) = -1.$$

The symbolic statements are

$$Vq = TVq, \quad UVq, \\ Sq = \pm TSq.$$

Therefore, also,

$$V^2q = -T^2Vq, \quad S^2q = T^2Sq.$$

The equation $S^2q - V^2q = T^2q$ may now be written

$$S^2q + T^2Vq = T^2q,$$

and hence, θ being an appropriate angle, it may be assumed that

$$Sq = Tq \cos \theta, \quad Vq = Tq UVq \sin \theta.$$

By the introduction of these expressions for scalar and vector the quaternion is presented in a new binomial form

$$q = Tq(\cos \theta + UVq \sin \theta),$$

one of great importance and utility.

The formula last written is a particular case of a more general geometric law. A recent interpretation makes quaternion symbols represent straight-line segments (their directions include) in four-dimensional space.* Interpreted in this way quaternions are called *directors*. It is shown that if two quaternion directors be perpendicular to one another their quotient is a vector. Let θ be the angle between p and q , let s be the director perpendicular dropped from the terminal extremity of q to p , and r the director from the origin

* "Transactions of the American Mathematical Society (Vol. 2, pp. 183-214, and Vol. 3, pp. 46-59).

(intersection of p, q) to the foot of this perpendicular. Then by geometric addition

$$q = r + s$$

and

$$q/p = r/p + s/p;$$

and s/p , being the quotation of a pair of mutually perpendicular directors, is a vector. Hence, since if ρ be the ratio Us/Up , it is a unit vector,

$$q/p = \frac{Tq}{Tp} (\cos \theta + \rho \sin \theta).$$

When $p=1$ this equation reduces to the one previously written for the value of q . In this particular case θ becomes the angle formed by the quaternion director q with the axis of real quantities, or scalar axis. When p and q are both vectors the formula expresses the fact, on which Hamilton early places emphasis, that the ratio of two vectors is in general a quaternion, but that if the vectors meet at a right angle the ratio is another vector, if they be parallel it is a scalar. But the formula also shows that these statements are true of quaternions in general.

The two parts of the equation last written present the quaternion under its three most fundamental aspects:

1. It is the ratio of two directed, non-positated,* straight-line segments.

2. It is the sum of a number and a directed, non-positated vector.

3. It is the product of a tensor (tensor of q/p) and of a versor, the latter being expressed in terms of its angle θ , and its vector axis ρ .

The geometrical and kinematical interpretations of geometric addition and subtraction involve no special difficulties. They are fully explained in a variety of treatises in which this subject has its natural place, particularly in those parts of mathematical physics where the composition of velocities and of forces is explained. The first full exposition of the subject was given in the celebrated 'Barycentrische Calcul' of Möbius, published in 1827, and was, therefore, well known about 16 years before the invention of the calculus of quaternions by Hamilton.

The non-commutative character of multiplication greatly enlarges its powers of expression and discrimination, but it also introduces troublesome transformation processes and calls for extended analysis. Fully expressed, the quaternion product has the double form $q()q_1$ and involves eight scalar quantities. A first step in its analysis resolves it, in either of two important ways, into simpler factors:

1. Since by the law of association

$$q()q_1 = 1[q()1]q_1 = q[1()q_1]1,$$

it consists of the two special commutative operators $q()1, 1()q_1$, applied in succession, or simultaneously, at pleasure.

2. It is always possible to determine four versor quaternions r, s, r_1, s_1 , that satisfy the following conditions:

$$Uq = rs = sr, \quad Uq_1 = r_1s_1 = s_1r_1,$$

and

$$Sr = Sr_1, \quad Ss = Ss_1.†$$

* Not placed in a definite position.

† "Proceedings of the American Association for the Advancement of Science" (Vol. 33, 1884, pp. 55-56).

The given product then assumes the form $mq()q_1 = mr[s()r_1]r_1 - 1 = ms[r()r_1 - 1]s_1$, where m is a number. It consists of a tensor factor and two rotational transformations $r()r_1 - 1, s()s_1$ which are commutative and may be applied simultaneously, or in succession.

The interpretation of the special products $q()1, 1()q_1, r()r_1 - 1, s()s_1 - 1$, as motions, "turns," and "rotations," generally in a space of four dimensions, has been successfully achieved.* An adequate account of them, however, would expand this notice beyond permissible limits. No accurate description of the motion represented by the general product $q()q_1$ has yet been given.

A simpler case than any of the preceding is the product $q()q - 1$. Its complete interpretation as a rotation in three-dimensional space was an early achievement by Hamilton himself. The motion consists of a rotation through twice the angle of $q(q$ being given in the form $m[\cos \theta + \rho \sin \theta]$) about the vector of q as an axis; that is, any vector, placed at the origin, moves through the angle 2θ , on the surface of a cone having its vertex at the origin.†

Quaternion multiplication may be expressed in terms of matrices. This fact was first established by Peirce,‡ afterward verified by Spottiswoode,§ but more explicitly by Cayley.|| It has also been shown that every similarity transformation in four variables is expressible as a quaternion product.|| Such facts as these bring out clearly the multiple character of the quaternion algebra.

The further development of the theory of quaternions, which follows the exposition of fundamental principles outlined in the preceding paragraphs, includes the deduction of the formulæ of scalar and vector products and quotients, the interpretation and transformation of quaternion expressions in general, the differentiation of quaternions, the solution of equations, especially of equations of the first degree, and the analytical theory of quaternions.

But although the works of Hamilton and Tait contain a large mass of material concerning particular quaternion transformations, the general Analytical Theory of Quaternions has yet to be written. A brief outline sketch of a method is given by Cayley in the sixth chapter of Tait's Treatise.

Applications.—It is impossible, in the space permitted to this notice, to do more than name some of the subjects in which the method of quaternions finds its applications. The most important of these to which writers have thus far given attention are the following:

* See Hathaway in "Transactions of the American Mathematical Society" (Vol. 3, 1902, pp. 46-59), and Stringham in "Proceedings of the American Association for the Advancement of Science" (Vol. 33, 1884, p. 56).

† Tait's 'Treatise on Quaternions' (3d ed., pp. 75 and 289).

‡ In a footnote in Linear 'Associative Algebra,' *American Journal of Mathematics* (Vol. 4, 1881, p. 132).

§ In 'Proceedings of the London Mathematical Society' (Vol. 4, 1872, pp. 156-159).

|| In Tait's 'Treatise on Quaternions' (3d ed., p. 148), and Cayley's 'Mathematical Papers' (Vol. 12, pp. 311-313).

¶ In 'Transactions of the American Mathematical Society' (Vol. 2, 1901, pp. 186, 187). See also the references to Cayley and Klein on page 184 of this volume, and 'Compte Rendu du deuxième Congrès International des Mathématiciens' (Paris, 1900, p. 336).

The theory of matrices; orthogonal transformation; geometry of the straight line, of the plane, of the sphere, of the cyclic cone, of surfaces of the second order, of curves and surfaces in general, and of planes in four dimensional space; kinematics of a point, of a rigid system and of deformable systems; axes and moments of inertia; statics of a rigid system; kinetics of a rigid system; precession and nutation; the problems of the pendulum; geometrical and physical optics; electrodynamics; the solenoid; applications of the

operator, $\nabla = i \frac{d}{dx} + j \frac{d}{dy} + k \frac{d}{dz}$, and of Laplace's operator ∇^2 , to physical analogies, to line, surface and volume integrals, to the stress function; application of the ∇ integrals to magnetic problems; the hydrokinetic equations; applications of ∇ in connection with Taylor's theorem and the calculus of variations.

By far the greater portion of extant knowledge of quaternions, both of the theory and of its applications, is due directly to Hamilton and is published in the 'Elements,' but the applications to physical problems were mainly contributed by Tait and are embodied in the 12th chapter of his 'Treatise.'

History.—The development of the quaternion calculus as an analysis of space relations was the work of Sir William Rowan Hamilton, Andrews professor of astronomy in the University of Dublin and royal astronomer of Ireland. The effort to create a new calculus of this type was a natural sequence of the many attempts that had been made to interpret geometrically the so-called imaginary and complex algebraic expressions of the forms $a\sqrt{-1}$ and $a + b\sqrt{-1}$. These attempts are recorded in the earlier works whose titles are given in the following bibliography.

Hamilton laid the foundations of the new subject during the years 1833-43. In November of the latter year his first paper on 'Researches respecting Quaternions' was presented to the Royal Irish Academy. His first full exposition of quaternion theory was published in 1853 in his 'Lectures on Quaternions,' a book of over 700 pages.

Meanwhile, in 1844, Grassmann published his now celebrated work, 'Die Ausdehnungslehre,' which occupies common ground with quaternion theory, but plans a much wider range of investigation than was contemplated by Hamilton in his system. The two systems have a common body of fundamental principles, but they have different points of view, different notations and in part different purposes. Both form the foundations upon which all subsequent work of the kind must stand.

Hamilton's 'Elements of Quaternions,' which still remains the storehouse of knowledge for its subject, was a posthumous work, published in 1866. A new edition has recently appeared in two volumes.

After the work of Hamilton and Grassmann had been finished the next most important forward step in the creation of new algebras was taken by Benjamin Peirce in his essay on 'Linear Associative Algebra,' presented to the National Academy of Sciences at Washington in 1870, subsequently published in the *American Journal of Mathematics* (1881). In this

work the author enumerates the types of linear associative algebras, and classifies them by a set of criteria which takes account of the number and the assumed laws of combination of their irreducible elements (extraordinaries, or vids). These laws are exhibited in the form of a series of multiplication tables.

Some of the more recent attempts to apply the quaternion analysis and the Ausdehnungslehre to physical problems have appeared under the title of 'Vector Analysis,' sometimes with modified, sometimes with wholly changed notations. Of these the contributions of Willard Gibbs and of Heaviside should be mentioned as of special importance. See VECTOR ANALYSES.

IRVING STRINGHAM,
Late Professor of Mathematics, University of California.

QUATRAIN, a poetical stanza of four lines, usually rhyming alternately; loosely, a poem of four short stanzas.

QUATRE-BRAS, kâtr-brâ ('four branches'), Belgium, in the province of Brabant, at the intersection of the main roads from Brussels and Charleroi and from Namur to Nivelles, about 20 miles south-southeast of Brussels. It is famous for the battle fought here, 16 June 1815, between the English under Wellington and the French under Ney. It was Napoleon's plan at the opening of the campaign of 1815 to fight the armies of the allies singly, as he felt himself unable to cope with their combined forces. At the head of an army of 129,000 men, supported by 350 guns, he made a rapid march into Belgium, crossing the Sambre almost before the allies were aware of his movements. His army was divided into three corps: the right wing, 48,000 strong, being under Grouchy; the centre, of 28,000 men, under the emperor himself; and the left wing, of 48,000, under Ney. The Prussians and English under Blücher and Wellington lay between the French and Brussels. With the right wing and centre of his army Napoleon furiously attacked the Prussians, who, after a severe struggle, retired upon Wavre 16 June. On the same day Ney attacked Wellington at Quatre-Bras. The English, 32,000 strong, repulsed Ney, and maintained their position, though at a loss of over 5,000 men, including the Duke of Brunswick. The English general, hearing of the retrograde movement of the Prussians, fell back on the 17th on Waterloo, where the decisive battle was fought on the following day. See WATERLOO.

QUATRE-VINGT-TREIZE, kâtr-vân-trâz ('Ninety-Three'), a work of historical fiction by Victor Hugo, published in 1874. The

time is, as the title indicates, 1793. The scene is Vendée, during the civil war. In its style it displays much unevenness, but in its characters, vivid scenes and tragic catastrophe ranks among the author's best.

QUATREFAGES DE BREAU, kâtr-fâzh de brâ-ô, Jean Louis Armand de, French naturalist: b. Berthezène, Gard, France, 10 Feb. 1810; d. Paris, France, 12 Jan. 1892. He was graduated from the University of Strassburg and in 1832 settled in Toulouse where he practised medicine and shortly afterward founded the *Journal de Médecine et de Chirurgie de Toulouse*. In 1838-40 he occupied the chair of zoology at the University of Toulouse and in the latter year removed to Paris, where he made a special study of invertebrates. In 1850 he was appointed professor of natural history at the Lycée Napoléon, Paris, and in 1855 professor of anthropology at the Musée d'Histoire Naturelle, which post he occupied until his death. He was elected to the Academy of Sciences in 1852 and was widely known by his anthropological investigations. He was the first expounder of the doctrine of phlebenterism, and was strongly opposed to Darwin's theories. He was the author of many important works on zoology and anthropology, among which are 'Considérations sur les caractères zoologiques des rongeurs' (1840); 'De l'Organisation des Animaux sans vertèbres des côtes de la Manches' (1844); 'Recherches sur le Système nerveux, l'Embryogénie, les Organes des Sens, et la Circulation des Annelides' (1844-50); 'Physiologie Comparée, Métamorphose de l'Homme et des Animaux' (1862); 'Souvenirs d'un Naturaliste' (1854); 'Histoire Naturelle des Annelés Marins et d'Eau Douce' (1865); 'Les Polynésiens et leurs Migrations' (1866); 'La Rochelle et ses Environs' (1866); 'Rapport sur les Progrès de l'Anthropologie' (1867); 'Ch. Darwin et ses Précurseurs français' (1870), an attack on Darwinianism; 'La Race Prussienne' (1871); 'L'Espèce Humaine' (1877); 'Nouvelles Etudes sur la Distribution Géographique des Negritos' (1882); 'Hommes Fossiles et Hommes Sauvages' (1884); 'Introduction à l'Etude des Races Humaines' (1887-89); 'Théories Transformistes' (1892); a series of papers entitled 'Etudes sur les Types Inférieurs de l'Embranchement des Annelés'; and he also contributed a large number of articles to the *Revue des Deux Mondes* on the results of his scientific researches along the Atlantic and Mediterranean coasts and throughout Italy and Sicily.

QUATREFOIL, kâtr-foil, in heraldry, a bearing displaying a conventionalized flower of four leaves; in architecture, an opening or a panel divided by cusps or foliations into four leaves, or, more correctly, the leaf-shaped figure formed by the cusps. It is an ornament which has been supposed to represent the four leaves of a cruciform flower, and is common in the tracery of Gothic windows. Bands of small quatrefoils are much used as ornaments in the perpendicular Gothic style and sometimes in the decorated.

QUATREMERE, kâtr-mâr, Etienne Marc, French Orientalist: b. Paris, France, 12 July 1782; d. there, 18 Sept. 1857. He was educated at the Collège de France, was employed at the Bibliothèque Impériale in 1807, and in 1809 ac-

cepted the chair of Greek in the University of Rouen. He was elected to the French Institute in 1815, became professor of Hebrew at the Collège de France in 1819, and in 1838 was made professor of Persian in the School for Living Oriental Languages. He made numerous valuable translations and was author of important geographical and historical works in addition to his work as an Orientalist. He published 'Recherches Critiques et Historiques sur la Langue et la Littérature de l'Egypte' (1808); 'Mémoires géographiques et historiques sur l'Egypte' (1811); 'Mémoire le sur Nabateens' (1835); 'Histoire des Mongols de la Perse' (1836); 'Histoire des Sultans Mamelouks' (1837-45), etc. His extensive library, including a great number of old Eastern manuscripts, is preserved in the royal library at Munich.

QUATREMÈRE DE QUINCY, dè kân-sê, Antoine Chrysostome, French archaeologist and politician: b. Paris, 28 Oct. 1755; d. there, 8 Dec. 1849. He was prominent politically under the republic, consulate, empire and restoration, in 1791 having been deputy to the legislative assembly for Paris. After the dissolution of the assembly, he was 13 months in prison, and after the proscriptions of 1793 he became one of the leaders of the insurrection of 5 Oct. 1795, for which he was condemned to death. He was later acquitted and in 1797 represented the Seine in the Council of Five Hundred, but for his opposition to the revolutionists was banished, 5 Sept. 1797. The consuls recalled him in 1799 and in 1800 he was appointed secretary to the council of the Department of the Seine; later was appointed to the class of history and ancient literature in the National Institute; was made permanent secretary of the Academy of Beaux-Arts in 1816 and was editor in that department of the *Journal des Savants*; elected professor of archaeology at the Royal Library in 1818 and serving as deputy in 1820-21. He wrote 'Dictionnaire de l'Architecture' (1786-1825); 'Histoire de la vie et des Ouvrages de Rafaël' (1824); 'Canova et ses Ouvrages' (1834); 'Le Jupiter Olympien, ou l'art de la sculpture antique' (1814); a treatise on ancient sculpture in ivory and gold; 'Essais sur l'imitation dans les Beaux-Arts' (1823); 'Monuments et Ouvrages d'art antique restitués' (2 vols., 1826-28); 'Histoire de la vie et des Ouvrages des plus célèbres Architectes' (1836), etc.

QUATROCENTO, kwât-rô-chên'tô, in art, a term applied to the characteristic style of the artists of the 15th century, that is 1400 and odd; it was hard, rigid and peculiar in color as well as in form and pose. It was the intermediate stage of that progressive period of art which, commencing with Fra Angelico, reached excellence with Leonardo da Vinci.

QUAY, kwâ, Matthew Stanley, American politician: b. Dillsburg, York County, Pa., 30 Sept. 1833; d. Beaver, Pa., 28 May 1904. He was graduated from Jefferson College in 1850, studied law, was admitted to the bar in 1854 and elected prothonotary of Beaver County in 1856 and 1859. During the Civil War he was in active service as colonel of the 134th Pennsylvania regiment, being present at the battle of Fredericksburg; he was also assistant commissary general of Pennsylvania, State military agent at Washington and military secretary to

the governor. In 1865-67 he was a member of the Pennsylvania legislature; in 1872-78, and again in 1879-82, he was State secretary; recorder for the city of Philadelphia in 1878-79; and State treasurer in 1885. As early as 1869 he was secretary of the executive committee of the Republican State committee, and after that became the undisputed leader of his party in Pennsylvania. In national politics he was a member of the Republican national committee after 1885, and in 1888 was its chairman, conducting a successful presidential campaign. In 1887 he was elected United States Senator, serving continuously till 1899; in that year a deadlock in the legislature prevented his reelection. This was in part owing to the fact that in 1898, on the failure of the People's Bank where State funds were deposited, he had been accused of being party to a conspiracy for the misappropriation of public funds; the trial occurred in April 1899 and resulted in his acquittal. He was then appointed Senator *ad interim* by the governor and elected to the Senate in 1901 for the term expiring in 1905. In the Senate he was one of the strongest opponents of the Panama Canal. His power as a political organizer lay chiefly in his adroit methods of reconciling opposing factions and hostile interests. A striking example of this was his method of meeting the reform movement of 1902 by supporting as candidates for governor of the State and mayor of Philadelphia, men who were endorsed by the reformers and not prominent in the regular Republican organization, thus gaining the support of what might have been a dangerous opposition.

QUAY, an artificial landing-place on a water-course or harbor, usually of stone. It differs from a wharf, which is a structure built out from the shore on piles, whereas a quay is properly solid. See **WHARVES** and **WHARF CONSTRUCTION**.

QUAYLE, kwál, William Alfred, American Methodist clergyman and author: b. Missouri, 1860. He was graduated from Baker University, Baldwin, Kan., in 1885, was ordained to the Methodist ministry the next year and has since held prominent pastorates in Kansas City and Indianapolis. He was professor of Greek at Baker University, 1885-90 and president of that institution, 1890-92. In 1908 he was created a bishop. He has lectured widely and has published 'The Poet's Poet and Other Essays' (1897); 'A Hero and Some Other Folk' (1899); 'The Blessed Life' (1900); 'The Gentleman in Literature' (1902); 'The Prairie and the Sea' (1905); 'God's Calendar' (1907); 'The Song of Songs' (1910); 'The Climb to God' (1913); 'Beside Lake Beautiful' (1914); 'Recovered Yesterdays in Literature' (1916), etc.

QUEBEC, kwé-bék (Fr. ké-bék), one of the provinces of Canada, the largest in area and second in population, in British North America. Its capital is the city of Quebec.

Boundaries and Extent.—It is bounded on the north by Hudson Bay and Strait, on the east by Labrador and the Gulf of Saint Lawrence, on the south by the Bay of Chaleurs, New Brunswick and the States of Maine, New Hampshire, Vermont and New York and on the west and southwest by the province of Ontario. Its length is nearly 1,000 miles on a

due east and west course, its breadth from north to south 1,200 miles and its area 706,834 square miles (15,969 water). The annexation in 1912 of the district of Ungava (354,000 square miles), now called New Quebec, has doubled its area. It thus embraces nearly one-fifth of the total area of the Dominion. The surface of Old Quebec is varied and very picturesque, embracing several ranges of mountains and lofty hills, diversified by numerous rivers, lakes and forests.

Mountains.—The Notre-Dame, or Green, Mountains, a continuation of the Appalachian Range, extend along nearly the whole of the south side of the Saint Lawrence. That chain runs at varying short distances from the river, and, after crossing the frontier and the State of Vermont, joins the Alleghanies. The highest altitude reached in the province is Mount Logan in Matane County (3,708 feet). The Laurentian Mountains skirt the northern bank of the same river and the Ottawa, somewhere near and somewhere at a distance of 10, 15 or 30 miles from the banks; but 130 miles west of Montreal, cross the Ottawa and curve in the direction of Kingston, whence they run westward to the shores of lakes Superior and Huron.

Rivers, Lakes and Islands.—Quebec abounds in large rivers, bays and lakes. The Saint Lawrence, 1,900 miles to the head of Lake Saint Louis and navigable for large ocean-going ships as far as Montreal, flows through almost the entire length of the province, receiving, a short distance above Montreal, the waters of the Ottawa, a river 685 miles in length. That last river is more abundant in water than the Nile and the Rhine and has large tributaries, the rivers Gatineau and Lièvre (Hare), which are over 200 miles long and three others extending over 100 miles to the north. The Saint Maurice, which rises in Lake Oskelaneo and empties into the Saint Lawrence at Three Rivers, is over 325 miles in length and is remarkable for its enormous flow of water and its falls. The principal, named Shawenegan, Grand 'Mère, La Tuque, Les Piles, are wonderful water powers, 150,000 horse power now having been developed. Large pulp mills and paper factories have been erected at Grand 'Mère and at Shawenegan, a few years ago and are now the centre of large and progressive towns. The rivers Batiscan, Sainte Anne, Jacques Cartier and Montmorency, the last named famous for its falls, also enter the Saint Lawrence from the north. The Saguenay (405 miles) rising in Lake Saint John and flowing into the Saint Lawrence at Tadoussac, is one of the most remarkable bodies of water in the world, varying in depth from 100 to 1,000 feet. It is the great outlet of the Lake Saint John, into which flow six long rivers; the principal one (the Peribonca) is 400 miles long and navigable for 30 miles. The Richelieu, draining Lake Champlain, discharges into the Saint Lawrence from the south and so do the Saint Francis, Chaudière, Chateauguay, Yamaska, Etchemin, Bécancour and from the north, Assumption, Matawan and du Loup. The rivers of New Quebec include the Big Nottaway, Rupert, Eastmain, Great Whale and Hamilton rivers. The principal lakes in the province are Melville (1,298 square miles), Mistassini (975),

Payne (747), Saint John (350). At three places the Saint Lawrence enlarges and forms lakes, named Saint Francis, the Saint Louis and the Saint Pierre. The principal islands in the river Saint Lawrence are the islands of Montreal, of Orleans, near Quebec, Anticosti and the Magdalen Islands, situated in the Gulf of Saint Lawrence, 50 miles north of Prince Edward Island.

Forests.—The province of Quebec abounds in forest lands, which extend to nearly 100,000 square miles, and the numberless rivers and their branches make the handling of lumber extremely easy. The territory on the north side of the Saint Lawrence River is covered with forests which are to all practical purposes valueless owing to the abundance of small growth. Along the river Manicouagan and the Gulf and river Saint Lawrence, the timber is not only of good quality but grows in great quantity, including even scattering pine of value. Extending westward from the Manicouagan to the eastern watershed of the Gatineau, pine of the best quality is found and lumbering has been successfully carried on for a number of years. In the district from which the Saguenay and its branches draw their waters is a vast quantity of pine, spruce, larch and other woods. In the district drained by the Saint Maurice and its tributaries pine and spruce are most abundant.

In the Lower Ottawa region, including the vacant and waste lands of the Crown on the northern tributaries of the Lower Ottawa and embracing the valleys of the rivers Assumption, Dunord, Petite Nation, the Blanche and du Lièvre, in all 11,256 square miles, are to be found poplar, white and red pine, spruce, tamarack and birch. In the Upper Ottawa territory is a great pine-growing district, but, while it is more valuable than the forests of the southern part of the province, it has not been worked to the same extent as that part, where the marvelous growth of brown birch, cedar, walnut, maple and pine has been a valuable source of income. Scattered throughout the province are to be found elm, beech, ash and cherry trees. About 175,000 square miles have been set apart as forest reserves. It is estimated that the forests of the province still contain 50,000,000,000 feet of standing pine. The value of the lumber cut was (1916) \$13,722,883, and of pulpwood production \$6,840,489. Since 1911 the exportation of unmanufactured timber has been forbidden and the result has been the creation of a valuable pulp-wood industry.

Mines.—There is no coal in the province. The Laurentian formation, in the central portion of the province, holds thick beds of limestone and iron ore,—titanic and magnetic, phosphate, plumbagine, mica and large deposits of graphite. Farther west the Laurentian formation is succeeded by the Potsdam sandstone. On this rests a dolomitic limestone and the limestone of the Lower Silurian Age, known as the Chazy and Trenton groups, are affording the best building stone of the province. There are many other minerals in the province of Quebec; but a few of them only are worked, namely, asbestos, ochre, chrome, copper, lead, silver and gold. There were 8,263 workers employed in the mining industry in 1916, the value of production for that year being \$13,070,566, an increase of 14 per cent over the preceding year. Of the total the products of the mines are valued

at \$7,982,430, and building materials at \$5,088,136; the former show an increase of 52.8 per cent; and the latter a decrease of 18.5 per cent. The values of the principal products were: asbestos, \$5,182,205; cement, \$2,525,841; copper and sulphur ore, \$1,273,724; brick, \$742,163; magnesite, \$525,966; chromite, \$299,070. The Quyon mine, opened April 1916, and from which shipments were in that year made of the value of \$129,267, is probably the largest producer of molybdenite in America.

Climate.—The cold in Quebec in winter is generally steady; the thermometer often registers 20° below zero and the snow falling to a great depth lies on the ground from November until April. The extreme heat of summer, which is generally warm and pleasant, is indicated at 90°. But it is only exceptional that it runs up to that figure. Autumn, which lasts six or eight weeks, is the finest season of the year.

Agriculture.—Vegetation develops rapidly; there is a rich and loamy soil in much of the country. In the large valleys of the Saint Lawrence, of the Ottawa River, of the Matapedia, of the Richelieu, in the whole region of Lake Saint John, and in the eastern townships of the province, farming is the chief industry. The principal crops are wheat, barley, oats, rye, peas, buckwheat, potatoes, clover, hay and corn. The lands lying in the vicinity of the State of Vermont are given to stock raising to a greater extent than to farming, and dairying has become an important branch of the trade of that district. In 1916 there were 660 butter factories, 885 cheese factories and 445 combined cheese and butter factories, the products having a total value of \$22,761,252. In the stock-raising districts horse and cattle breeding has assumed the most important position, while sheep and swine are also raised to a great extent. Quebec had (1917) 379,276 horses, 91,102 milch cows, 958,010 other cattle, 849,148 sheep and 712,087 swine. The total area under field crops in 1916 was 4,590,200 acres and the value \$102,937,300. The following are some of the details:

The field crops in 1916 totaled \$102,937,300 in value and were as follows:

PRODUCT	Area in acres	Total yield, bushels	Total value
Spring wheat.....	64,000	960,000	\$1,786,000
Oats.....	1,073,000	24,411,000	18,796,000
Buckwheat.....	101,000	1,919,000	2,322,000
Mixed grains.....	91,000	1,843,000	1,825,000
Potatoes.....	112,000	14,672,000	14,232,000
Turnips.....	10,000	2,650,000	1,272,000
Hay and clover.....	2,985,000	5,224,000	57,464,000
Fodder corn.....	31,000	248,000	1,476,000

Fisheries.—The total value of the fisheries of the province was in 1916 \$2,076,851, and gave employment to nearly 9,000 men.

Trade and Commerce.—The value of the imports entered for home consumption by the province for the year ending 31 March 1917 was \$270,024,440 and exports \$551,111,934. Quebec has about 800 bank branches with clearing houses at Montreal, Quebec and Sherbrooke. Quebec has 7,158 manufacturing establishments, with capital of \$549,000,000; 141,000 employees, and annual products worth \$351,000,000. There are 2,064 vessels owned in the province of an aggregate tonnage of 123,052 tons. The annual receipts of the province are over \$9,500,000.

Education.—Educational matters in the province of Quebec are under control of a

superintendent of public instruction assisted by a council and divided into committees for the management of Roman Catholic and Protestant schools, respectively. Compulsory school age is from 5 to 16 years. The schools are maintained partly by local taxation and partly by government grants and are individually controlled by local boards. There are in the province 5,988 elementary schools and 721 model schools. In the elementary schools there are 252,000 pupils. The total number of schools, universities and colleges in the province is given at 7,156, teachers 16,634, pupils 470,839. Chief among the higher institutions of learning are Laval University at Quebec and McGill University and the Presbyterian College at Montreal.

Government.—The system of government established in Canada under the Union Act of 1867 is a federal union having a general or central government controlling matters essential to the general development, the permanency and the union of the whole Dominion and a number of provincial organizations, each governed by a lieutenant governor, nominated and removable by the government of the Dominion and advised by a council responsible to the people's representatives and with a legislature composed in Quebec of two houses— a council of 24 members appointed by the Crown, each representing a special territorial division and an elective assembly of 81 members. The Parliament of Canada consists of a Senate and a House of Commons. The Senate, as at present constituted, has 81 members, 24 of whom are from Quebec. The House of Commons consists at present of 234 members, the basis of representation, fixed under the provisions of the Act of Confederation, being that the province of Quebec is always to have 65 representatives and each of the other provinces such a number as will give the same proportion of representatives to its population as the number 65 bears to the population of Quebec as ascertained by a decennial census. In the province of Quebec the qualifications for the electoral franchise are ownership or occupancy of real property; position as teachers or clergymen after five months' domicile in electoral district; income or personal property of specified amount— real, or real and personal, valued at \$300, \$200 and \$100 (fishermen). Income, renters, \$100; others, \$300. Absentees in the United States may vote if they have returned with their families and have resided in an electoral district one month before election. Voting in elections is by ballot. No property qualification is demanded from a member of the Commons, nor is he limited to a residence in the district for which he is elected. Hotel bars within the province were closed from 1 May 1918; and from 1 May 1919, no further licenses for the sale of intoxicating liquor were to be issued.

Municipal Institutions.—The municipal organization of the province comprises townships, counties, being rural districts of no definite area, parishes, villages with a population of over 40 families, towns and cities erected by legislative authority. No definite figure of population is requested. The townships, parishes, towns and villages are administered by a mayor and councillors; the cities by a mayor, councillors and aldermen.

Judiciary.—The judiciary of the province consists of appeal (King's Bench), superior,

circuit and district courts. The Superior Court and King's Bench judges are appointed by the governor-general in council. Appeal can be had from superior courts to King's Bench, and from King's Bench to the Supreme Court of Canada presided over by a chief justice and five associate judges. Final appeal, except in criminal cases, lies, by leave, to the judicial committee of the Privy Council of England. Police magistrates and justices of the peace, appointed by the provincial government, also have their place in the administration of justice.

Crown Lands.—The crown lands of the province not yet settled form an area of nearly 200,000,000 acres, of which about 75,000,000 are available for settlement and 7,000,000 acres have been surveyed, and are controlled by the government and administered by the minister of crown lands. They are sold at from 20 to 60 cents an acre, and the purchaser is required to take possession of the land within six months of the date of the sale, to occupy it during two years, and to fulfil various other obligations stipulated in the deed of sale.

Population.—The population of the province in 1911 was 2,003,232 (1916 estimate 2,309,427), almost equally divided into rural and urban, and giving an average density of 5.69 persons per square mile. Roman Catholics comprise 86 per cent of the population, which is 80.5 per cent French and 19.5 per cent English speaking. Of the French-speaking wage-earners, 36 per cent are engaged in agriculture and 24 per cent in manufacturing and mechanical industries. The numerous churches, colleges and convents of the province attest at every turn the wealth and power of the Church, and the tourist finds the whole land practically parceled out among its faithful, as far as concerns the nomenclature of the settlements and villages.

Twenty miles east of the city of Quebec, on the banks of the Saint Lawrence, is the church of Sainte Anne de Beaupré, more particularly known as La Bonne Sainte Anne, who for two centuries has won fame in Canada for miraculous cures. This historic place rests on a little plateau under the shelter of a lofty mountain of the Laurentides, and consists of a straggling street of wooden houses, with steep roofs and projecting eaves. Here one will see, on the fête of Sainte Anne and at other fixed times, a mass of people from every part of Canada, as well as from the United States. A handsome gray stone church attests the faith of the thousands who in past years have offered their supplications at the shrine of La Bonne Sainte Anne. Piles of crutches are deposited in every available corner, as so many votive offerings from the countless cripples who have been cured or relieved. The relic through which all the cures are said to be effective consists of a part of the finger-bone of Sainte Anne, which was sent in 1668 by the Chapter of Carcassonne to Monseigneur de Laval.

The Country Life.—The situation of many of the villages of Quebec is exceedingly picturesque when they nestle in some nook by the side of the river or bay, or overlook from some hill a noble panorama of land and water. The spire of the stone church rises generally from the midst of the houses, always making the most conspicuous object in the surrounding

landscape. The houses are, for the most part, built of wood. The roofs are often curved, with projecting eaves, which afford a sort of veranda, under which the family sit in summer evenings. Some of the more pretentious structures, especially the inns, have balconies running across the upper story. Many of the barns and outhouses have thatched roofs, which are never seen in any other part of Canada. The interiors are very plainly furnished, in many cases with chairs and tables of native manufacture. A high iron stove is the most important feature of every dwelling in a country where the cold of winter is so extreme. Whitewash is freely used inside and outside, and there is, on the whole, an air of cleanliness and comfort in the humblest cottage. No class of the population of Canada is more orderly or less disposed to crime. Early marriages have always been encouraged by the priests, and large families are the rule in the villages. The temperate habits of the people make them valuable employees in mills and manufactories of all kinds, and until a recent period there was a steady exodus from the province to the manufacturing towns of New England. A large proportion of the men employed in the lumbering industry of Canada is also drawn from the province of Quebec. In commercial and financial enterprises, however, the French Canadians cannot compete with their fellow citizens of British origin, who practically control the great commercial undertakings and banking institutions of Quebec, especially in Montreal. But they are remarkably progressing in that line. Nor, as a rule, could they compare formerly with the English population as agriculturists. But they have largely improved their methods of farming, and they have established in every parish, butter and cheese factories. The French population also had less enterprise and less disposition to innovations. But they do adopt new machines and improved agricultural implements like the people of the other provinces of Canada.

Literature.—In times past there was no native literature, and little general culture, except in small select circles at Quebec and at Montreal; but during the past half-century, with the increase of population, the establishment of colleges and universities, the dissemination throughout of classical education, and the development of self-government, the French Canadians have created for themselves a literature, which shows that they inherit much of the spirituality and brilliancy of their race. The histories and poems have attracted much attention in France, and some of their literary works have been awarded prizes by the French Academy. In history mention should be made of the names of Garneau, Ferland, Sulte, Tassé, Turcotte, Dionne, Casgrain, Gosselin, Le Moine, Gagnon, Myrand, etc.; in poetry, Cremazie, Chauveau, Fréchette, Poisson, Lemay, Chapman and many others; in science, Hamel, Laflamme, De Foville, etc. In art some progress has been made, and young men go to the Paris schools from time to time. The only sculptor of original merit that Canada has yet produced is Hébert, a native of Quebec, whose statues of eminent Canadians stand in several places. Science has not made as much progress as belles-lettres and history, though

Laval University has among its professors men who have done creditable work in mathematics, geology, chemistry and physics. In romance, however, little has been done, except by Marmette, Lemay and a few others.

History.—Jacques Cartier discovered and explored the river Saint Lawrence in 1533, but it was not until 1608 that Samuel de Champlain founded the present city of Quebec, which, at the end of 12 years, had a population of only 60 persons. The Récollets were the first missionaries. The Jesuits came to the settlement in 1625, and thereafter played a leading part in its history. Montreal was founded in 1642 by Maisonneuve; but for many years as an agricultural or commercial settlement, New France, as it was called, remained a failure, its only trade being the fur trade. A change came under Louis XIV, when a systematic effort began to make the colony the starting point of a French and Catholic empire which should embrace the whole of the continent. The result of this policy was a long contest between the two races, which began in 1689 with the second advent of Count Frontenac as governor of New France, and ended in 1759 with the capture of Quebec by a British army under Wolfe. The capitulation of Montreal in 1760 completed the English conquest of Canada, which, with all its dependencies, was in 1763 formally ceded to the British Crown.

The policy of the conquerors toward New France was, from the appointment of General Murray, a liberal one, and in 1774 took definite form in what was known as the Quebec Act, by which the British Parliament assured the French Canadians the free exercise of their religion, the enjoyment of their civil rights and the protection of their own civil laws and customs. The act also annexed larger territories to the province of Quebec, and provided for a governing council partly composed of Catholics, and for the administration of the criminal laws as in use in England. There was, however, constant strife between the conquering and the conquered race, the object of which was to amalgamate the two races, and to put an end to it, Parliament, in 1791, divided Canada into two provinces—Lower Canada, or Quebec, for the French, and Upper Canada (now Ontario) for the British, many of whom had fled thence from the United States at the close of the Revolutionary War. Each province was to have, besides the governor who represented the Crown, a legislative council nominated by the Crown, and an assembly elected by the people for four years. But the two races were not separated by the division of the province, and in 1841, after a long and stormy agitation, a reunion of the provinces was effected under the name of the Province of Canada, and with it the establishment of responsible government. The legislature consisted of a council and assembly, each province being represented in the assembly by 42 members, 84 in all, elected by the people; and the council numbered 20 members, appointed by the Crown. This arrangement lasted until 1867, when it gave way to a union of the provinces of British North America. The way for confederation was cleared by a convention of representatives of all the provinces, held in Quebec, in October

1864, which unanimously adopted a set of resolutions embodying the conditions on which the provinces, through their delegates, agreed to a federal union. These resolutions were duly laid before the various legislatures and adopted in the shape of addresses to the Queen, whose sanction was necessary to embody the wishes of the provinces in an imperial statute; and in February 1867 the British North America Act was passed by Parliament. On 1 July of the same year the union of the provinces of Canada, Nova Scotia and New Brunswick was proclaimed under the name of the Dominion of Canada, the names of Upper and Lower Canada being changed at the same time to Ontario and Quebec.

ADOLPHE B. ROUTHIER,
President of the Court of Admiralty for the Province of Quebec.

QUEBEC, founded by Samuel Champlain in 1608, is the seat of the Provincial Government. It is situated on the northeastern end of a narrow promontory, which is bounded to the southward by the river Saint Lawrence, and to the northward by the valley of the Saint Charles. The cliffs on the Saint Lawrence side run up the river for many miles, and average between 200 and 300 feet in height. The earliest buildings were constructed along the narrow shore at the foot of Cape Diamond, and gradually extended to what is now the lower town. In the course of time Champlain transferred his residence to the summit of the rock, and soon other buildings arose which marked the beginnings of the upper town. In a few places in the lower town a part of the river bed has been reclaimed, particularly near the old palace of the Intendants; but with these exceptions the streets follow the original plan. Winding roads, cut out of the rock, and flights of steps, lead from the lower to the upper town, the streets of which bear the names originally given to them. Quebec claims the distinction of being the one walled city of the north, and although the march of progress has introduced many innovations, it has been powerless to destroy the impress of the founder. At the time of the death of Champlain, in 1635, the entire population of Quebec was only 80 persons. But shortly after, as a result of the circulation of the "Relations" of the Jesuits in the mother country, an effort was made to colonize New France. The first fruits of this movement were the establishment of the Ursuline Convent and the Hotel Dieu, in 1639. These two institutions, which have ever since exercised a beneficent influence, were founded by the zeal of two noble women, Madame de la Peltre and Madame d'Aiguillon, whose names are consecrated in the pages of Canadian history. The Ursuline Convent has continued to be the centre of education for the girls of Quebec, both French and English. In this institution, the Old World and the New run side by side. The rule of the order is the same as in 1639. In the nave of the convent chapel repose the remains of the Marquis de Montcalm; and in the Chapel of the Saints, through all the startling changes of two centuries, the Votive Lamp, first trimmed by Marie Repentigny in the days of the French régime, is still kept steadfastly burning. The Seminary of Quebec

founded in 1668, is another institution in which the customs of the Old World are preserved. From the Seminary sprang the famous Laval University, the chief seat of learning in the province for the French population.

From the earliest times Quebec has been fortified. In 1535, Jacques Cartier built a rude fort at the mouth of the river Lairet, and in 1608 the "Habitation" constructed near the site of the present Champlain Market, was mounted with cannon to protect the inhabitants against the incursions of the Indians. Twenty years after a fort was erected on the crest of the rock, which served as a residence for the invader Kertk until 1632. Frontenac put into execution the first scheme for enclosing the town with a wall, but like all the French works of defense, the profit of the contractor was of more importance than the solidity of the workmanship. In 1720, a new scheme was undertaken. Large sums of money were expended from year to year, but when Wolfe came before Quebec in 1759, the foot of rotten walls could be seen 500 yards off. After the battle of the Plains, temporary works were constructed in front of the old walls. In 1783 a temporary citadel was commenced beyond the line of fortification, and the remains of these works, still visible, are erroneously referred to in local guide books and maps, as of French origin. In 1823 the British government undertook a comprehensive scheme of defense, the main parts of which are in excellent repair to-day. The picturesque old gates have been demolished, and in two instances, arches in keeping with the walls have replaced them, and the Martello Towers, overlooking the Plains of Abraham, stand as originally built. The Fortress of Quebec comprises the citadel on Cape Diamond, where the governor general's quarters are situated, the town lines, and the forts on Levis Heights. The citadel is garrisoned by the Royal Canadian artillery.

Quebec has nine parish churches belonging to the Catholics, four others in the charge of chaplains, and 13 chapels attached to religious communities, open to the public. The Church of England is represented by the English Cathedral and six churches, while the Methodists, the Presbyterians and the Baptists have each separate places of worship. The first parish church was erected in 1633 under the name of Notre Dame de la Recouvrance; but it was destroyed in 1640. In 1647 the French cathedral was commenced under the name of Notre Dame de la Paix, in commemoration of the peace concluded with the Iroquois. It was opened in 1650. The pillars of the present church date from 1647, the towers from 1684 and the remainder of the building from 1745. The paintings in the cathedral brought from France are very valuable and there are many costly vestments of an early date. Notre Dame des Victoires, in the lower town, was commenced in 1688 under the name of Notre Dame de la Victoire. After Phips besieged Quebec in 1690, a pilgrimage to the church was organized, and in 1711, on the destruction of Walker's fleet off Egg Island, the name of Notre Dame de la Victoire was changed to Notre Dame des Victoires. During the siege of Quebec in 1759, only the walls were left standing. Of the modern Catholic churches the Franciscan's is the most beautiful. It was

built for the perpetual adoration of the Blessed Sacrament.

After the Treaty of Paris in 1763, English services were held by the Protestants in the church of the Récollets. The drum was beaten at half past 10 for the Mass of the Récollets, at the conclusion of which the fathers tolled the bell for the English service. The English cathedral, situated on the site of the Récollet Church, was commenced in 1804. The paintings in the archbishop's palace, and in the Ursuline Convent and Laval University, are amongst the most valuable in Canada. In the governor's garden is a monument which always appeals to strangers. It is a plain granite column. On one side it bears the name of "Wolfe," and on the other the name of "Montcalm," and on the base this simple inscription:

Mortem virtus communem
Famam Historia
Monumentum Posteritas
Dedit.

It is the only instance on this continent of a common monument to the victor and the vanquished. Near the jail is the monument to Wolfe, with its inscription "Here died Wolfe Victorious," and a little farther on, along the Sainte Foy Road, is the column to the memory of the French who fell in their endeavor to retake Quebec in 1760. The name of the English general, Murray, is also prominent on this column. These monuments of stone are more eloquent than words of the harmony existing between two races, mingling with each other, and still preserving their own laws, their language and their religion. In the upper and lower town markets, may be witnessed scenes typical of French Canadian habitation life, and even in the streets through which the electric cars run we may trace, at all times, the features of the French régime. The boys of the seminary still wear the long blue coat piped with white, with green sashes, as they did 200 years ago. The nuns passing to and fro in their prescribed costumes; the priests in their cassocks, the habitants in their old-fashioned vehicles or rude sleighs, look out of place in the 20th century; and yet the people of Quebec would not welcome any change. The city, however, keeps pace with the times in other respects. The streets are well paved, well lighted, always clean. All the waste places possible are converted into small gardens, and there is an excellent civic administration. The hotel accommodation, especially since the construction of the Chateau Frontenac, is the best in Canada. Laval University has a library of 125,000 volumes. The Parliament buildings and grounds, the city hall, the courthouse and other public buildings, are better than in the larger cities of Canada, and yet there is still so much which belongs to a by-gone age. The tercentenary of the founding of the city was fittingly celebrated in 1908. According to the census of 1911, the population of Quebec was 78,710 (estimate of 1916, 110,000), a very large proportion of which is composed of French.

Most of the English reside in the upper town, although there is no marked division. The Grande Allée is the principal thoroughfare, and contains many fine dwellings. At one time the lumber trade flourished, and as large fortunes were amassed the wealthy merchants and traders built country seats along the

Sillery Road; but they are now mostly deserted. Shipbuilding was also a great industry for many years, as very large vessels were built there, but nothing now remains. The leather and shoe trade still give employment to thousands. The commercial and financial institutions are controlled to a large extent by the English. The lower town is principally devoted to business, and the suburbs of Saint Roch and Saint Sauveur to manufacture and the dwellings of the working classes. The small arms and the ammunition for the militia are manufactured in Quebec. The port of Quebec is always active in season, and it is the landing place of immigrants; but Montreal has absorbed a great deal of the commerce. The bridge which is being built across the Saint Lawrence will bring the grain from all quarters to Quebec, and its future commercial life may assume large proportions. As the seat of government, it will always retain a prominent place, and in its immediate vicinity there are so many places of picturesque and historic interest: Wolfe's Cove; the place where the gallant Montgomery fell in 1775; the Heights of Levis; the Island of Orleans; the village of Beauport, with Montcalm's headquarters; Indian Lorette; the falls of Montmorency, with Wolfe's house; the Shrine of Sainte Anne, and the numerous places which may be reached by electric railway, the Canadian Pacific Railway, the Grand Trunk Railway, the Intercolonial Railway, the Great Northern, the Quebec and Lake Saint John, and the boats of the Canada Steamship Lines. But the perpetual charm of Quebec, apart from its magnificent situation, lies in the fact that it is the cradle of New France; that upon its lofty rock a drama was fought which decided the fate of a continent; that from its institutions, scarcely altered by the flight of three centuries, men went forth to rescue for civilization an untamed wilderness, and paved the way for the great Republic of the United States.

A. G. DOUGHTY,

Author of 'Quebec Under Two Flags.'

QUEBEC, Battle of. See COLONIAL WARS IN AMERICA.

QUEBEC, Siege of, in the American Revolution. After Ethan Allen and Benedict Arnold (qq.v.) had captured Ticonderoga and Crown Point (qq.v.), Continental Congress, at Washington's earnest solicitation, decided to conquer Canada as a measure of self-defense. One expedition under Gen. Philip Schuyler (q.v.) was to proceed northward by way of Lake Champlain and another under Arnold through Maine, both converging on Quebec. Schuyler sent Richard Montgomery (q.v.) in advance to reduce Saint John's, about 150 miles north of Ticonderoga, while he returned to Albany to push troops to the front. On 13 Oct. 1775 a small British fort at Chamblet was captured but to offset this Sir Guy Carleton (q.v.), British commander at Montreal, captured Allen and a band of 80 men who, without consulting Montgomery, had attempted to surprise the garrison at Montreal. Allen was sent in irons to England. After an abortive attempt by Carleton to drive off the invaders, Saint John's surrendered 1 November, whereupon Carleton abandoned Montreal and fled to Quebec, Montgomery occupying Montreal 13

November and later following Carleton with about 300 men.

Meanwhile, with 1,050 troops, Arnold had begun his march, reaching Point Levi, opposite Quebec, 9 Nov. 1775. On the 13th he crossed the river with his army, which had been reduced to 600 troops, occupied the heights near the Plains of Abraham, and attempted to surprise the city, but finding the garrison prepared for defense, retired to await Montgomery's arrival which occurred 1 December. The combined troops numbered 900 and, owing to the rigors of the winter march, were in an emaciated condition. For three weeks the Americans bombarded the city ramparts without effect and Montgomery decided to attempt the reduction by assault. Dividing the force, the two commanders made a simultaneous assault from different points on the night of 31 Dec. 1775. Montgomery attacked the lower town but in attempting to storm a blockhouse was killed with several others and his troops retreated. Arnold assaulted the town from his side but his leg was shattered by a ball and the command devolved upon Capt. Daniel Morgan (q.v.) who captured the first and second barriers. But when Montgomery had been repulsed, the troops from that quarter attacked Morgan on the rear and finally, after an obstinate fight, he surrendered, the prisoners numbering 426. Arnold escaped capture and, collecting his dispirited troops, maintained an imperfect blockade of the city until the spring of 1776, when he was succeeded by Gen. David Wooster (q.v.), who made several ineffectual attempts to capture the city. A large body of British troops arrived from England and the Americans were compelled to fall back on Montreal; finally on 18 June they evacuated the province, going to Crown Point. QUEBEC ACT, the administrative measure passed by the British Parliament in 1774, for the purpose of adding the regions extending to the Ohio and Mississippi over which the French had exercised authority, to the province of Quebec, which had been limited by the Proclamation of 1763 to an area of about 100,000 square miles along the central Saint Lawrence. The act established also the body of the French customary law as the permanent civil code of

the region, the introduction of English civil law among the French-speaking inhabitants having been found impracticable; it admitted also to a partial franchise the Roman Catholic population, guaranteeing them freedom of public worship, confirming them in the possession of their ancient churches and revenues, but withholding from them representative institutions, authority over this vast territory being vested in a council appointed by the executive power of Great Britain.

The act, which had for its main motives the welfare of the French Canadians and the security and unhampered progress of the colonies and of colonial trade, was viewed with indifference by the Canadians, was unpopular in England, aroused the indignation of the older American colonies and had considerable influence in directing the early course of the Revolution. To it the Declaration of Independence refers as follows: "Abolishing the free system of English laws in a neighboring province, establishing therein an arbitrary government, and enlarging its boundaries so as to render it at once an example and fit instrument for introducing the same absolute rule in these colonies." For opposing views on the measure consult Coffin, 'The Quebec Act and the American Revolution' in *The Yale Review* (1895); Bancroft, 'History of the United States', Vol. IV, chap. V (1884); Hart, 'The Quebec Act 1774' (1891); and McArthur, D., 'Canada under the Quebec Act' in *Canada and Its Provinces* (Vol. III, 1914).

QUEBRACHO, kě-brā'chō, the name given to several trees of different genera, but with similar qualities, indigenous to South America, valuable alike for their wood and their bark. The red quebracho (*Loxopterygium lorentii*, family *Anacardiaceae*) is very hard, but splits easily. The bark and wood are used in tanning. The white quebracho (*Aspidosperma quebracho*) is used for wood-engraving. Its bark contains an alkaloid (quebrachin) and is used therapeutically as a remedy for asthma, being employed as a decoction and a tincture. Its action is to lower the action of the heart without harmful result.

QUECHUA, kă'chwā. See **QUICHUA**.

QUEEN, the wife of a king, or the female sovereign of a kingdom. In Britain she is either merely a queen-consort, the king's wife, and his subject, not his equal, on an equal footing, save as provided by law, with the rest of his subjects; or she is a *queen-regent*, regnant, or sovereign, holding the crown in her own right, as did Elizabeth or Victoria. The *queen-dowager*, widow of the king, retains most of the privileges pertaining to a queen-consort. It is high treason to compass or imagine the death of a queen-consort, or to violate her person; and if the consort is consenting, she is equally guilty. Under the constitution of Prussia, Sweden, Belgium and other European countries a woman cannot be queen-regent.

QUEEN ADELAIDE ARCHIPELAGO, belonging to Chile, at the west entrance to the Strait of Magellan; separated from the mainland by Smyth Channel. The islands are mountainous and present rugged faces to the sea. The summits of some are snow capped during the year; but the vegetation at the base is varied and for a short season luxuriant.

QUEEN ANNE STYLE. See **RENAISSANCE**.

QUEEN ANNE'S BOUNTY, a fund established for the enlargement of the incomes of the holders of the poorer incumbencies in the Established Church of England, and to aid incumbents in rebuilding parsonages by granting advances of money. It was created by royal charter of Queen Anne, confirmed by act of the parliament, by which the first fruits (the whole of the first year's profits) of all spiritual preferments, and the 10th part of the annual profits of the same—both of which, prior to the reign of Henry VIII, had been paid into the papal treasury, but were then annexed to the crown—are set aside to form this perpetual fund. The fund is administered by a board of governors consisting of high ecclesiastical dignitaries, the speaker of the house of commons, privy councillors, chancellors of the universities, etc. It amounts to over \$35,000,000, and the annual grants and benefactions to nearly \$300,000. To encourage private benefaction, the board of governors may give \$1,000 to incumbencies of not exceeding \$225 a year where an equal or greater sum is voluntarily contributed.

QUEEN ANNE'S POCKET-MELON. See **MELONS**.

QUEEN ANNE'S WAR. See **COLONIAL WARS IN AMERICA**.

QUEEN OF THE ANTILLES, a name given to the island of Cuba on account of its size and superior natural advantages.

QUEEN CHARLOTTE ISLANDS, a group off the coast of Canada, belonging to the Province of British Columbia; about 100 miles from the mainland and 135 miles northwest of Vancouver Island. Area, 5,100 square miles. The largest Islands are Graham and Moresby, each about 160 miles long and 70 miles wide. The surface of Graham is rolling land; but the other islands are rugged and mountainous. Dense forests and a luxuriant growth of small plants cover the islands. Copper, anthracite coal, iron ore and gold-bearing quartz are found here; fishing is the chief occupation. The inhabitants, believed to number under 1,000, are mostly Indians.

QUEEN CHARLOTTE SOUND, the body of water which separates Vancouver Island (q.v.), on the north, from the mainland of Canada.

QUEEN CITY, or **QUEEN OF THE WEST**, names applied to Cincinnati, Ohio, on account of its commercial importance, at a time when it was larger than Chicago and Saint Louis.

QUEEN CITY OF THE GOLDEN GATE, a name given to San Francisco on account of the name of the strait north of the city, and also that the city was practically the gate or entrance to the gold fields of California.

QUEEN CITY OF THE LAKES, a name given to Buffalo, N. Y., on account of its commercial importance and its commanding position on the Great Lakes.

QUEEN ESTHER. See **MONTAUR, ESTHER**.

QUEEN MAB. Shelley's 'Queen Mab' was written in the months of quixotic enthusiasm following the youthful poet's first marriage,

and was printed for private distribution in 1813. When in 1821 a pirated edition appeared, Shelley characterized the piece as "villainous trash." It is indeed tediously long, vapid and visionary, but it possesses, in addition to its considerable metrical interest, a good deal of value as a mirror of the author's mind at 18 and as evidence of the charm exerted upon sensitive spirits of the age by the radical philosophy of the 18th century. Copious argumentative notes indicate as sources of inspiration such writers as Godwin, Gibbon, Hume, Voltaire, Rousseau, and Locke. In his survey of history Shelley attributes most of the ills which mankind has suffered to false religion, monarchical institutions, marriage, customs, conventions and the eating of meat. In this sanguine vision of the future he represents a world regenerated through the emancipation of reason and passion, which we are to believe will lead to the abolition of priests, kings, prisons and marriage vows and to the adoption of a vegetable diet. There is little or no common sense in the composition but an abundance of intense young heady ardor for reforming society by that short method dear to the Godwinian idealist—letting every one do as he pleases, a method which in practice requires resort to the guillotine.

STUART P. SHERMAN.

QUEEN-OF-THE-MEADOW, or **QUAKER-LADY**, a *spiræa*. See **MEADOW-SWEET**.

QUEEN OF THE PLAINS, a name applied to Denver, Colo., which rests on an eminence on the western border of the Great Plain and seems to overlook the vast region of plain-land stretching off to the east.

QUEEN'S BENCH. See **COURT**.

QUEENS' COLLEGE, Cambridge, England, founded in 1448 by Margaret of Anjou, queen of Henry VI, and refounded in 1465 by Elizabeth, queen of Edward IV, is administered by a president and 13 foundation fellows. Richard Andrew donated the site and Dokett, the first master, secured the endowment. A fixed proportion of the revenues of the college is paid to a scholarship fund. There are nine church livings in the gift of the college and one in that of the president. There are in addition four exhibitions named after their founders, and the president distributes \$650 per annum in grants to deserving students of limited means. About 200 students are enrolled. The college buildings are among the most interesting in the university and include four courts of small size. In a tower in the pump-court are the rooms inhabited by Erasmus (1506). There are about 30,000 volumes in the library. John Fisher, Thomas Fuller and Bishop Pearson were members of the college. Consult Gray, J. H., 'Queens' College' (London 1899).

QUEEN'S COLLEGE, Oxford, England, was founded in 1340 by Robert de Eglesfield, chaplain to Philippa, queen of Edward III, for a provost and 12 scholars. The college now consists of a provost, from 14 to 16 fellows, about 25 scholars and two Bible-clerks. Six of the scholarships, annual value \$400, are called Eglesfield scholarships, and are awarded to natives of Cumberland and Westmoreland. There is also a scholarship called the Jodrell

scholarship, of the annual value of \$450 and tenable for four years; and a considerable number of other exhibitions. The college presents to 23 church-livings. The college buildings are of the 17th century; the hall was designed by Sir Christopher Wren. Wyclif, Edward the Black Prince, Henry V, Addison, Bentham, Jeffrey, Mitford and Wycherley are numbered among its distinguished alumni. See OXFORD UNIVERSITY.

QUEEN'S COLLEGES, Ireland, until 1909 the names of three institutions of higher education situated at Belfast, Cork and Galway. They were chartered in 1849 in pursuance of an act of Parliament passed in 1845, granting \$500,000 out of the consolidated fund for their establishment. The colleges were opened in 1850, being connected with Queen's University, then also instituted as a degree-conferring body. The corporate body of each college consisted of the president and professors, and the general government and administration was vested in a council consisting of the president and six members, elected by the professors from among themselves. In 1909 the Belfast College received a separate charter as Belfast University, while those at Cork and Galway became constituent colleges of the new National University (q.v.).

QUEEN'S METAL. See BRITANNIA METAL.

QUEEN'S PIGEON, a magnificent ground pigeon (*Couva Victoriae*), inhabiting the islands of the Indian Ocean, named after Queen Victoria. See GOURA.

QUEEN'S UNIVERSITY. Queen's University, situated at Kingston on Lake Ontario, is one of the largest universities of Canada. It has faculties of arts, applied science, medicine, education and theology; and holds a yearly summer school for instruction in certain subjects in the arts and education courses. Degrees in agriculture are granted, but the final two years in this course must be taken at the Ontario Agricultural College at Guelph. The university extension department provides for instruction extra-murally in the arts course, but degrees are not granted unless a portion of the course is taken in attendance.

The university was incorporated by royal charter on 16 Oct. 1841, and on 2 March 1842 the first session opened with 11 students. Dr. Thomas Liddell, formerly minister of Lady Glenorchy's Church in Edinburgh, was the first principal. The institution was modeled on the democratic lines of the Scottish universities with a view to bringing higher education within the reach of the humblest aspirant. One of the pressing reasons for its establishment was to provide for the education of the Presbyterian clergy in Canada. As no religious tests were imposed on students, the denominational character of the institution faded into the background, and, although the university was nominally under the ægis of the Presbyterian Church, its real function became that of a great national university, drawing students of all creeds from every province of the Dominion. In 1911 the nominal relationship with the Church, which prevented the obtaining of government assistance, was formally severed by the Presbyterian General Assembly, and in

April 1912 constitutional changes effected by an act of the Dominion Parliament made the university undenominational in form as it had long been in reality. The divinity faculty was federally incorporated the same year under the style of Queen's Theological College. It is still controlled by the Presbyterian Church, but its degrees are granted by the university, to which it is affiliated. The history of the early years of Queen's is the story of a continual struggle against straitened circumstances. In 1867 the grant from the provincial government was withdrawn and the crisis came in the following year when the failure of the Commercial Bank swept away the greater portion of the endowment fund. The situation, however, was faced with determination. Rev. William Snodgrass, who was then principal, at once began an energetic canvass for a new endowment fund. His efforts resulted in the collection of \$113,000 and the crisis was safely passed.

Snodgrass was succeeded in 1877 by George Monro Grant, a figure of outstanding personality whose efforts made Queen's a university of the first rank. He was a man of tremendous energy, sound in judgment and utterly fearless in the expression of his opinion on public questions. Endowed with the faculty of inspiring his associates with his own enthusiasm he soon attracted to Queen's, mainly from the universities of Scotland and England, a number of young men of energy and ability and so imbued them with the "Queen's spirit" of service and self-sacrifice that, despite tempting offers from larger institutions of learning, they remained with Queen's to work out her and their destiny. Grant's principalship was a period of great expansion. The country was canvassed from the Atlantic to the Pacific for funds, new chairs were founded, new buildings erected and the movement began to sever the existing relations with the Presbyterian Church. On his death in 1902 the institution had become one of the largest and most influential in Canada, and he himself was ranked among the foremost Canadian publicists.

The university has remained true to the democratic principles on which it was founded. The Scottish plan of allowing students a wide choice of subjects within certain prescribed limits has been followed. Students and professors are in close personal touch with one another, the seminary system being adopted in the honor classes. There are no Greek letter or other societies making for class distinctions between the students. Discipline is maintained by the students themselves under sanction of the university authorities, and students' courts having the power to pass sentence of expulsion are held annually in each faculty to discipline offenders.

The university has been a pioneer in the movement for coeducation. In 1870 classes in English and other subjects were formed for women and in 1878 courses leading to a degree were thrown open to them. In 1880 coeducation was extended to the medical course, whilst in 1883 a separate women's medical college was opened in affiliation to the university. This, however, was closed the following year as similar facilities were then offered to women elsewhere in Canada. The university has a residence for women.

A university extension department extends the benefits of university instruction to the people at large. Portions of the arts courses may be taken extra-murally and the services of the professors are available for popular lectures. Research and practical work of the faculty of applied science in mining and metallurgy has done much to further mining development in Canada, especially that of the Cobalt district. In 1914 the department of political and economic science in conjunction with the Canadian Bankers' Association instituted a course in banking designed mainly to assist men already in the service of the Canadian chartered banks. This course is divided into two parts, the associates' course, in which the university merely acts as examiner for the Canadian Bankers' Association, and the Fellows' course, in which it supplies tuition by correspondence as well. In 1914 the registration in these courses was 680 and 375 respectively.

Physical culture classes under medical supervision are compulsory for all first-year students except those taking military training. Since 1910 Queen's has maintained as part of the Canadian militia the Fifth Company of Canadian Field Engineers (Queen's). On the outbreak of the Great War in 1914 the services of these student-engineers were at once requisitioned to lay out Valcartier Camp, near Quebec, where the First Canadian Expeditionary Force of 33,000 men was concentrated. This work finished, the majority of the company proceeded to France for service on the firing line. The university also supplied the imperial government with No. 5 Stationary Hospital (Queen's) which served in the Mediterranean field of operations at Cairo and later in France. In addition two batteries of artillery, the 46th and the 50th, were recruited from Queen's men. In all the university furnished for active service 897 officers and men, of whom 664 were for service overseas. The university buildings overlook Lake Ontario and are built of Kingston limestone. They consist of the Theological building, the new Arts building, the gift of the city of Kingston; Grant Convocation Hall, erected by the students in honor of the late Principal Grant; Ontario Hall (physics, mineralogy and geology); Fleming Hall (mechanical and electrical engineering); Gordon Hall (chemistry); Nicol Hall (metallurgy); the Medical building, the Medical Laboratories building, the gymnasium and the observatory. The general university library, which contains 70,000 volumes and is particularly rich in original documents, pamphlets and reports bearing on Canadian history, is housed in the Theological building, but a new library building the cost of which was met by a donation of \$150,000 from the chancellor, Dr. James Douglas, has been erected.

The faculty of applied science was incorporated in 1893 as the School of Mining, in affiliation to the university. When the latter in 1912 threw off the ties connecting it with the Presbyterian Church, steps, concluded in 1916, were taken to amalgamate the School of Mining with the university. The faculty of applied science provides instruction leading to the degrees of B.Sc., B.Sc. (Agr.), M.Sc. and D.Sc. Four-year graduate courses are offered in mining and metallurgical engineering, analytical and applied chemistry, mineralogy, geology, chem-

ical and metallurgical engineering, civil engineering, mechanical engineering and electrical engineering. The faculty of arts has a four-year undergraduate course and grants the degrees of B.A., M.A. and Ph.D. The degrees of B.Paed. and D.Paed. are conferred by the faculty of education, whilst that of B.D. is given by the Theological College. The honorary degrees of LL.D. and D.D. are given by the university. The faculty of medicine grants the degrees of M.D., C.M., D.Sc. and D.Ph. The first classes were held in 1854. In 1866 it was separated from the university and conducted under the name of the Royal College of Physicians and Surgeons at Kingston, but it again became an integral part of the university system in 1892. Clinical work is provided in the Kingston General Hospital, the Hotel Dieu, Rockwood Hospital for the Insane and the Oliver Mowat Hospital for Tuberculosis.

Queen's has an endowment fund of \$750,000 and an annual revenue from all sources of approximately \$300,000. The administration of the university is vested in the board of trustees, the university council and the senate. The board of trustees consists of the chancellor, the principal and the rector, as ex-officio members, representatives from the university council, the benefactors, the graduates and co-operative members; and has charge of the external administration of the university including the finances. The senate consists of the principal, the vice-principal, the principal of Queen's Theological College, the deans of the several faculties and one or two professors elected from each faculty. It has to do with all matters of an academic nature, including instruction. Faculty boards consisting of the teaching staffs of the various faculties relieve it of much detail work. The university council is an advisory body, made up of the chancellor, the trustees, the senate and an equal number of members elected by the graduates. It elects the chancellor, except when two or more candidates are nominated, in which event he is appointed by the alumni and the registered graduates. He is the highest officer of the university and as such presides at convocation, the meetings of the university council and statutory meetings of the senate. See CANADA—HIGHER EDUCATION.

QUEENSBERRY, John Sholto Douglas, 8th MARQUIS OF, English sporting character: b. England, 20 July 1844; d. London, 31 Jan. 1900. He served in the navy when a youth, and in the army from 1859 to 1864. His life was marked by much eccentricity. He was one of the founders of the Amateur Athletic Club in 1860 and was a recognized authority on boxing and part author in 1867 of the prize-ring rules which bear his name. He sat in the House of Lords as a Scottish representative peer (1872-80). In 1881 he published 'The Spirit of the Matterhorn,' a meditation in blank verse. He also came into prominence as a supporter of secularism, and as a defender of Charles Bradlaugh (q.v.), in 1882 creating a scene in a London theatre by rising in his seat and denouncing as "an abominable caricature" the imaginary free-thinker in Tennyson's 'Promise of May.' He was instrumental in effecting the imprisonment of Oscar Wilde (q.v.) in 1895, by defending the libel action

brought against him, on the grounds that what he had published was "justifiable and for the public benefit."

QUEENSBERRY, William Douglas, 4th Duke of, British sportsman: b. 1724; d. London, England, 23 Dec 1810. He was devoted to horse-racing and was familiarly known as "Old Q." He was vice-admiral of Scotland in 1767-76 and was then first lord of the police until the office was abolished in 1782. He succeeded to the dukedom in 1778 and was created a British peer in 1786. In 1789 he was removed from his office of gentleman of the bedchamber and held no further office. He was notorious for his excesses and was satirized by Robert Burns in 'The Laddies by the Banks o' Nith,' and in an 'Epistle to Mr. Graham of Fintrie.' Wordsworth addressed him in a sonnet as "Degenerate Douglas," and he was the original of the Earl of March in Thackeray's 'Virginians.'

QUEENSBERRY PLOT, a presumed Scottish Jacobite conspiracy, so called owing to the connivance, in 1703, of the Proto-rebel James Douglas, second duke of Queensberry, with the intrigues of Simon Fraser, Lord Lovat (q.v.), to involve their common enemy, the Duke of Atholl, in a supposed conspiracy against Queen Anne. Atholl discovered the sham plot and revealed it to the queen. Queensberry, who had been a tool of Fraser, was compelled in consequence to resign his offices.

QUEENSLAND, Australia, a state of the commonwealth, prior to 1901 a colony. It occupies the northeastern portion of the continent, north of New South Wales and South Australia, and east of the latter. The land boundaries are mostly artificial, the meridians of 138° and 141° east and the parallels of 29° and 26° south; on the east it has the Pacific, on the north the Gulf of Carpentaria. The most northern part of it, forming York Peninsula, extends to Torres Strait, and a considerable portion is within the tropics. It has an area of about 670,500 square miles, and is divided into 12 large districts (besides smaller divisions) namely, Moreton, Darling Downs, Burnett, Port Curtis, Maranoa, Leichhardt, Kennedy, Mitchell, Warrego, Gregory, Burke and Cook. Besides the capital of the state, Brisbane, the other important towns are Ipswich, Rockhampton, Toowoomba, Townsville, Mackay, Maryborough, Gympie, Bundaberg, Charters Towers, Normanton, Cooktown and Somerset.

Topography.—A series of parallel ranges of mountains traverses the state from north to south near the coast, among the numerous local names being Cook Range, Razorback Range, Dawes Range and Glasshouse Mountains. The Dividing and M'Pherson ranges run from the head of the Dumaresq River in the south eastward to the coast. There is a long range in the interior running east and west and forming a watershed between rivers flowing north and those flowing south. The peak of highest elevation is Wooroonooran in a spur of the Coast Range known as the Bellenden Ker Range. Its elevation is 5,400 feet. The coast which extends for some 2,250 miles, is indented with numerous inlets, bays and harbors, some of the chief being Moreton Bay, Hervey Bay, Port Curtis, Keppel Bay, Broad Sound, Repulse Bay, Halifax Bay, Rockingham Bay, Princess Char-

lotte Bay. Among the numerous islands along the coast are Stradbroke, Moreton and Bribie, at Moreton Bay; Fraser or Great Sandy Island, Curtis, Whitsunday, Hinchinbrook, all off the east coast; Prince of Wales, Banks, Thursday and others in Torres Strait; and the Wellesley Islands, in the Gulf of Carpentaria. Parallel to the east coast and at no great distance runs the Great Barrier Reef.

Hydrography.—There are four great river-systems: (1) Rivers draining to the Pacific Coast, the chief being the Burnett, the Fitzroy, the Burdekin and the Brisbane, the last entering Moreton Bay and having Brisbane, the capital, near its mouth; (2) those draining to the Darling, comprising the Macintyre, the Condamine or Balonne and the Warrego; (3) those draining to the Gulf of Carpentaria, among them being the Flinders, the Leichhardt, the Albert, the Nicholson, the Gilbert, the Mitchell; (4) those flowing into the interior, the chief being the Victoria or Barcoo, which enters Lake Eyre in South Australia as Cooper's Creek, the Herbert, and the Diamantina or Mueller.

Geology and Mineral Resources.—The Cretaceous system is extensively developed in the west and northwest, covering an area of about 200,000 square miles. Tertiary strata occur along the coast of the Gulf of Carpentaria and elsewhere, and occupy a considerable area. The Desert or Eolian Sandstone, which renders extensive tracts barren and almost uninhabitable, is variously classed as Upper Cretaceous or Tertiary. Palaeozoic formations also cover a large part of the country, especially along the eastern coast. About 14,000 square miles are Carboniferous, and some 40,000 of Devonian age, and the Cambrian and Silurian also occur. Mesozoic formations older than the Cretaceous are well developed in some places. Granitic rocks are very extensively developed in the east coast districts and they have been estimated to occupy about 100,000 square miles. More than 30,000 square miles are covered by volcanic rocks. Gold was discovered about 1858, and there are now more than 25 gold-fields in the state, among them being Gympie (near Brisbane), Charters Towers (on the Burdekin), Cape River, Croydon, Cloncurry and Jordan Creek. The production of 1915 is valued at £80,436,391. Other minerals of importance are copper, tin and coal, but antimony, silver, lead, bismuth, manganese, plumbago, asbestos and precious stones are also obtained. Bluestone, limestone, freestone, granite and other rocks are quarried. The coal production in 1915 amounted to 1,024,273 tons.

Climate.—The climate is healthful and the temperature comparatively equable. The mean temperature at Brisbane is 69°, the extreme range being from 35° to 106°. In the more northern parts the climate is tropical. The rainfall in the interior is scanty and variable; the mean at Brisbane is about 35 inches. In some parts it is now supplemented by means of artesian wells.

Forestry, Fauna, etc.—The state possesses various kinds of valuable timber, such as the red cedar, the Moreton Bay pine, the cypress pine and several species of eucalyptus. Some of the grasses are valuable as fodder plants. There are several good indigenous fruits. The animals and plants are similar to those of the

rest of Australia. Crocodiles are found in some of the northern rivers. Pearl-fishing is extensively carried on in the extreme north, and the bêche-de-mer, dugong and other fisheries are also of some importance.

Agriculture.—The soil and climate are suited for the production of all the ordinary cereals, as well as maize, tobacco, coffee, sugar, cotton and other plants. Maize is more generally cultivated than any other cereal crop. The next crop in point of importance is sugar. All kinds of semi-tropical and English fruits are abundantly grown. Sheep-farming is the chief industry and cattle-breeding is also important.

Commerce, Manufactures, Communications.—The principal imports are apparel and haberdashery, cottons and woollens, flour, iron and steel, boots and shoes, tea, spirits, hardware, machinery, wine, etc.; and the principal exports, wool, gold, tin, sugar, preserved meat, cotton, wood, hides and skins. The imports come mainly from the United Kingdom and the United States. The value of imports for 1915-16 amounted to £7,000,912; the exports to £8,106,123. A duty of 5 per cent is charged on imports of yarns, woven fabrics, paper, stationery, etc.; and duties at other and even higher rates on other articles.

The manufactures are comparatively unimportant; the chief industrial establishments are sugar-mills, steam saw-mills, soap-works, distilleries, breweries, carriage-works, butter-factories, boot and shoe factories, cordial-factories, etc. There are 4,840 miles of state-owned railway open. The most important lines are the three which reach the coast at Brisbane, Rockhampton and Halifax Bay. In 1915 the registered shipping consisted of 164 sailing vessels of 6,107 net tons, and 124 steamers of 14,753 net tons.

Government, Education and Religion.—The government is vested in a governor, who is the king's representative, an executive council, and a parliament of two houses, the legislative council and the legislative assembly. The council consists of 38 members appointed by the Crown for life, no limit being put to the number; and the assembly of 72 members elected by the people for three years, and representing 72 electoral districts. In 1914 women were also enfranchised. The revenue for the year ending 30 June 1917 was estimated at £7,876,548; the expenditures at £8,034,624. Education is free and secular in the state schools, of which there are 1,550 elementary schools, six high schools and 10 grammar schools. There are also 147 private schools. A university was established for the state at Brisbane in 1911. There is no state church, each religious denomination being entirely self-supporting. Anglicans predominate, with Roman Catholic second. There are a number of charitable institutions maintained by public subscription supplemented by state endowment. The commonwealth also pays an Old Age and Invalid Pensions.

History.—The first settlement of Queensland took place in 1825, when the territory was used as a place of transportation for convicts, who continued to be sent there till 1839. In 1842 the country was opened to free settlers. It was originally a part of New South Wales, until in December 1859, it was organized as a separate colony under its present name instead

of the earlier one of Moreton Bay District. In 1901 it became one of the states of the Australian commonwealth. Pop 1916, est. 687,480. See AUSTRALIA.

Consult Russell, H. S., 'The Genesis of Queensland' (Sydney 1888); Gray, R., 'Reminiscences of India and North Queensland, 1857-1912' (London 1913); Mathew, J., 'Two Representative Tribes of Queensland' (London 1914); Weedon, T., 'Queensland Past and Present' (Brisbane 1897); and Pugh's 'Queensland Almanac, Court Guide, Gazetteer, etc.', an annual publication (Brisbane).

QUEENSTOWN, Ireland, a seaport town and important naval station, in the county and nine miles southwest of Cork, on Great Island, which is situated in Cork Harbor, and rises abruptly to a considerable elevation. The streets rise above one another, and present a picturesque appearance. It has a splendid Roman Catholic cathedral. Queenstown is almost solely dependent on its military and naval establishments. It is an important port of call for mail steamers and was formerly known as COVE OF CORK. In honor of Queen Victoria's visit in 1849 the name was changed to Queenstown. Pop. about 8,000.

QUEENSTOWN, Ontario, Canada, village and picturesque summer resort of Niagara County, on the Niagara River, near the mouth of the gorge, seven miles below the falls, and opposite Lewiston, N. Y. Pop. 400. The Brock monument, 185 feet high, on the heights overlooking the village, commands a magnificent prospect, and commemorates the battle of 12 Oct. 1812, when General Van Rensselaer commanding 6,000 United States troops near Lewiston, sent about 1,000 men across the river in the night to attack Queenstown preparatory to a further invasion of Canada. General Brock, the capturer of Detroit, commanded the British forces, but was killed early in the action. The rest of the American troops refused to cross the river, and the attacking party, overpowered by numbers, was compelled to surrender. The American loss in killed and wounded was 300; in prisoners 958; the British lost about 130 killed, wounded and prisoners.

QUEIROZ, kã-ê-rôs, José Maria Eça de. See EÇA DE QUEIROZ.

QUELPART, kwêl'pärt, **QUELPAERT**, or **TAMRA**, an island off the southern coast of Korea, about 62 miles from the mainland. Tamra is the native name of the island. In form it is nearly oval; area, about 750 square miles. It is mountainous, the highest point, Mount Auckland, or Han-ra-san, is 6,650 feet in height. This mountain is an extinct volcano; three well-defined craters exist, in each of which is a lake of pure water. One of the traditions held sacred by many of the natives is that from these lakes came the first three men of the world. The principal town is Chyei Chyu. The chief industries are fishing, agriculture, cattle-raising and manufacturing fine split-bamboo hats. Pop. 130,000. Consult Hamel, 'Narrative of Captivity in Korea' (in Griffis' 'Korea Without and Within,' New York 1885); Belcher, 'Narrative of H.M.S. *Samarang*' (London 1848), containing an account of the survey and mapping of the island by the officers of the British ship *Samarang*.

QUENSTEDT, kvén'stét, Friedrich August, German mineralogist and geologist: b. Eisleben, Germany, 9 July 1809; d. Tübingen, Germany, 21 Dec. 1899. He was educated at Berlin and in 1837 became professor of geology and mineralogy at Tübingen where he remained until his death. He made valuable investigations in geology and mineralogy and in the latter science was first to apply the analytic method to the study of crystalline systems. He wrote 'Methode der Kristallographie' (1840); 'Grundriss der bestimmenden und rechnenden Kristallographie' (1873); 'Handbuch der Petrefaktenkunde' (1851; 3d ed., 1882-85).

QUENTEL, kvén'tél, Heinrich, German printer: b. Strassburg; d. 1501. He established a press near the cathedral at Cologne and though the earliest dated work from his press is 'Fratris Astexani Opus de Casibus Conscientiae' (1479) yet the earliest low German version of the Bible, usually stated 1470, is undoubtedly from his types and probably from his press. The business was conducted in his name for some time after his death.

QUENTIN DURWARD, kwén'tin dər'-ward, a romance by Sir Walter Scott published in 1823. The scene of this tale is France during the reign of Louis XI; the hero, Quentin Durward, is a Scottish archer, who, having a relative in the Scottish Guards of the French king, goes to France to seek his fortune. The book was written at the flood-tide of Scott's popularity at home; the ebb began with 'St. Ronan's Well,' published six months later.

QUÉRARD, kā-rā'r, Joseph Marie, French bibliographer: b. Rennes, 25 Dec. 1791; d. Paris, 3 Dec. 1865. From 1819 to 1824 he was attached to a well-known Vienna book firm and while there prepared the first part of his 'La France littéraire,' in which he gives a complete bibliography of France for the 18th and the beginning of the 19th centuries, including not merely notices of French writers, but of foreign authors whose works had been reprinted or translated in France. The whole work appeared in 10 volumes (1827-42). Among other works of his are 'La littérature française contemporaine,' of which Quérard himself prepared only the first two volumes (1839-44); 'Supercheries littéraires dévoilées' (1845-56).

QUERCIA, kwär'chā, Jacopo Della, Italian sculptor: b. Quercia, near Siena, about 1371; d. 1438. He was the first Tuscan sculptor who combined observation of nature with study of the antique and thus reformed plastic art in Italy. His chief works are the sepulchral monument of Ilaria de Caretto in the cathedral at Lucca; a fountain adorned with the Madonna and emblematic figures of the virtues, Faith, Hope, Charity, Prudence, Justice, Temperance and Fortitude, at Siena; a marble font in the cathedral of the same city and the reliefs in the portal of the church of San Petronio at Bologna, which depicts five scenes in reliefs from 'Genesis,' five from the 'Youth of Christ,' nine figures of the prophets and a life-size Madonna and Saint Petronius. Consult Cornelius, 'Jacopo della Quercia' (1896).

QUERCITRON, kwér'sit-rōn, the inner part of the bark of the black oak (*Quercus velutina*), one of the finest of North American

oaks. It is of great economic interest through its yielding the dyestuff "quercetin" ($C_{15}H_{10}O_6$), known commercially as "yellow flavin." This substance exists in the quercitron bark in the form of its glucoside "quercitrin" ($C_{21}H_{30}O_{11} \cdot 2H_2O$). Quercitrin is also found in the market under the name of "red flavin," and is used in that form as a dye, but its color is less brilliant and less durable than quercetin.

Yellow flavin is obtained by digesting the powdered quercitron bark with a solution of common salt to separate the gummy ingredients, which are filtered out. The filtrate is dried and extracted with dilute ammonia, and while cold is treated with a slight excess of hydrochloric acid. The precipitate is removed, and the solution of the glucoside quercitrin, which remains as the filtrate, is boiled for half an hour, at the end of which time it has been hydrolysed into quercetin, which crystallizes out in the form of pale yellow needles. These are gathered from the solution while it is yet warm, drained and washed. Quercetin is a strong dye for mordanted wool, yielding colors varying with the mordant, as follows: Bright orange with tin; reddish brown with chromium; brownish orange with aluminum; and orange-black with iron.

QUERCUS, the generic name for oak (q.v.).

QUERES. See KERESAN.

QUERETARO, kā-rā'tā-rō, Mexico. See MEXICO—THE STATES OF.

QUERETARO, Mexico, capital of the state of Queretaro, distant from the City of Mexico by the National Railway 167 miles and by the Central 153 miles, and from El Paso, Texas, by the Central 1,071 miles and from Laredo, Tex., by the National 580 miles; elevation 5,904 feet above sea-level. Here is the famous Hercules Cotton Mill, one of the oldest and most extensive in the Republic, employing almost 2,000 operatives, and here are also several other manufacturing industries, including woolen mills. Some miles distant are the famous opal mines, which have been worked for centuries, producing enormous quantities of the precious stones, but which are now becoming gradually exhausted. The water supply is obtained from the mountains through a great stone aqueduct five miles in length. The city has a complete system of electric lighting, a well-equipped street railway and many substantial business structures. The Bank of Queretaro, with a capital of \$1,000,000, a branch of the National Bank and an agency of the Bank of San Luis Potosi supply the financial needs of the community. There are numerous churches, one of the oldest and most prominent of which is the Santa Rosa. The Civil College is the most notable educational institution. In this are taught law, engineering, chemistry, etc. There are two museums, one of which is devoted to history and the other to commerce; and a library connected with the Civil College contains 9,000 volumes. Other notable buildings are the Government Palace, built of basalt, the Iturbide Theatre and a bull-ring; there are also numerous parks. The city was founded by the Aztecs about 1440; was conquered by the Spaniards in 1531 and is noted in modern history as the scene of the capture, imprisonment and execution of Emperor Maximilian in

1867 by the Mexican government. Pop. about 38,000.

QUERN, a mill, especially a hand mill for grinding corn, used from early times among almost all races of humankind before the invention of water or windmills. The general form consists of two circular stones, the lower of which is slightly dished and the upper one pierced in the centre and revolved on a wooden or metal pin inserted in the lower. The grain is dropped with one hand into the central opening, while with the other the upper stone is revolved by means of a stick inserted in a small opening or hole near the edge. It is sometimes incorrectly confused with "churn" (q.v.).

QUESADA, *kā-sā'thā*, **Gonzalo de**, Cuban diplomatist: b. Havana, Cuba, 15 Dec. 1868; d. 1915. He was graduated from the College of the City of New York in 1888 and afterward studied at Columbia. He was secretary of the Cuban revolutionary party and associated with José Martí in the endeavor to effect Cuban independence. He served as special commissioner of Cuba to the United States in 1900, was Cuban commissioner to the Paris Exposition, and in 1901 became a member of the Cuban Constitutional Convention. In 1912 he became minister to Germany and served as delegate from Cuba to the third and fourth Pan-American conferences. He has published 'Patriotismo'; 'History of Free Cuba' (1898); 'Ygnacio Mora' (1894); 'La patria alemana' (1913), and edited José Maité's 'Obras literarias' (1900-11).

QUESADA, **Gonzalo Ximenes de**. See **XIMENES DE QUESADA**.

QUESALTENANGO, *kā-sāl-tā-nān'gō*. See **QUEZALTENANGO**.

QUESNAY, *kā-nā*, **François**, French economist; b. Méré, near Versailles, 4 June 1694; d. Versailles, 16 Dec. 1774. He was at first a surgeon, and in 1737 was made perpetual secretary of the surgeons' academy; but in 1744 he received a physician's certificate and became a favorite physician at the court of Louis XV. His works on professional subjects are wholly antiquated and he is best known as the chief of those economists whom Dupont de Nemours called the "physiocrats." The principal tenets of this school were that there exists a natural order, with which human government should interfere as slightly as may be, and that all wealth is derived from the soil. Extravagant praise was heaped on Quesnay, who was called the "European Confucius," while his 'Tableau économique' (1758) was styled by Laharpe "the Koran of economists." His economical works appeared in 1768. Consult Higgs, 'The Physiocrats' (London 1897).

QUESNAY DE BEAUREPAIRE, *dé bō-rē-pār*, **Jules**, French jurist and author, known also by the pseudonym **JEAN GLOUVET**: b. Saumur, 2 July 1838. He studied law, became for a time a journalist, later entered definitely upon a legal career and in 1889 was made procurator-general of the Paris Court of Cassation. In that capacity he appeared for the government before the Senate, constituted as a high court of justice with charges against Boulanger (q.v.) and the latter's accomplices, Dillon and Rochefort. In 1892 he was appointed president of the chamber of the Court

of Cassation, from which post he was compelled in January 1899 to retire, owing to the fact that his aggressive attitude in the Dreyfus revision was interpreted by his colleagues as an evidence of bias. Among his works are 'Le forestier' (1880); 'Histoires du vieux temps' (1883); 'L'étude chandoux' (1885); 'France, 1418-29' (1895); and 'Le Panama et la République' (1899).

QUESNEL, *kā'nēl'*, **Joseph**, Canadian poet and dramatist: b. Saint Malo, France, 15 Nov. 1749; d. Montreal, Canada, 3 July 1809. In service aboard a man-of-war he visited Pondichery, Madagascar, Africa, French Guiana, the Antilles and Brazil, thence reaching Montreal through the Mississippi Valley. The remainder of his life he spent in Montreal and Boucherville. He engaged in writing plays, songs and verse and composed some sacred music. His 'Colas et Colinette' (1788) was first produced in Montreal. Other productions were an operetta, 'Lucas et Lucille,' and the comedies 'L'Anglomanie' and 'Républicains Français.' His writings are collected in the 'Répertoire national' (Vol. I).

QUESNEL, **Pasquier** (**PASCHASIUS**), Roman Catholic theologian: b. Paris, 14 July 1634; d. Amsterdam, 2 Dec. 1719. In 1657 he entered the order of Oratorians, but subsequently through his publication of the 'Works of Leo the Great' (1675) with annotations, in which he maintained the independence of the Gallican Church, he incurred the displeasure of the Holy See, and as he refused in 1687 to subscribe to an anti-Jansenist declaration, he was obliged to take refuge in Brussels with Arnould (q.v.) where he employed himself in completing his edition of the New Testament with moral reflections. The Jesuits thereupon obtained from Philip V of Spain a writ through which Quesnel was taken in custody as guilty of Jansenism (1703). With the aid of his brother, however, he escaped and fled to Amsterdam, where he lived to see 101 passages in his New Testament condemned by the Holy See in the bull 'Unigenitus.'

QUETELET, *kēt'lā'*, **Lambert Adolphe Jacques**, Belgian statistician and astronomer: b. Ghent, 22 Feb. 1796; d. Brussels, 17 Feb. 1874. In 1814, he became professor of mathematics at Ghent, in 1819 was appointed to the same chair in the Brussels Athenæum and was lecturer in the Museum of Science and Literature, 1828-34. Quetelet superintended the erection of the Royal Observatory and was its first director from 1828 till his death. His writings on statistics and kindred subjects are very numerous, and among them may be named 'Sur l'homme et le développement de ses facultés, ou essai de physique sociale' (1835); 'Sur la théorie de probabilités appliquée aux sciences morales et politiques' (1846); 'Sur le système social et les lois qui le régissent' (1848); 'Histoire des sciences mathématiques et physiques chez les Belges' (1864), and 'L'Anthropométrie' (1871). He applied the mathematical methods of averages and probabilities to the study of man both as an individual and as a member of society.

QUETTA, *kwēt'tā*, British Baluchistan; city, on a railroad which belongs to the India railway system, and about 100 miles north of

Kheelat. It is a commercial and industrial centre for a large region; but it is of great strategic importance, on account of its position among high mountains and that it commands both Bolan and Khojok passes. It is strongly fortified, and has an arsenal and a garrison. It has become a flourishing place since 1876, when a British residency was established here. Pop. about 30,000.

QUETZAL, kêt-sāl', a very beautiful bird of the trogon (q.v.) family (*Pharomarcus morio*), intimately connected with the mythology and history of the Maya, Quiche and Nahuatl races of Mexico, Yucatan and Guatemala. The name of the bird in Aztec is derived from its bright green color. Its tail feathers, which are from two to three feet long, were used as decorations for priests of the Toltec god Quetzalcoatl and for people of noble birth. So much was it used in this connection and so stringent were the restrictions placed upon its use by persons other than those entitled to wear it, that the word came to have the sense of royal and sacred in the Aztec language. The Yucatecan king of Mayapam wore for a crown a plain golden circle surmounted with a plume of quetzal feathers. Only the king and the high nobles could wear these feathers which were used to mark very exalted rank in Mayapam, and such store was placed by the quetzal that the penalty of death was provided for any one killing one or wearing or having quetzal feathers in his possession. The plumage of the quetzal was commonly used as a distinctive badge of the Toltec god of the air, Quetzalcoatl (q.v.), the incongruous parts of whose compound name (quetzal-coatl, or feathered serpent) can only be properly explained when the fact is kept in mind that "quetzal" came to be used as the badge of royalty or high rank in both men and deities. The shield and the mace or baton of authority of Huixtocihuatl, were ornamented with quetzal feathers, and the long tail feathers of this bird were sculptured on stone in Yucatan, southern Mexico and Guatemala as the symbolical representation of the Maya and Quiché culture gods. Quetzalcoatl, the "Fair God," is presented in the form of a coiled serpent ornamented with feathers resembling those of the quetzal. Several stone effigies of him in this form are preserved in the National Museum of Mexico and others have been discovered in the ruins of ancient cities all the way from Central Mexico to Guatemala. Quetzal feathers were used as decorations for the armor of Mexican nobles in pre-conquest days and in the making of the wonderful feather pictures of the Aztecs and other cultured races of Mexico, and also in the manufacture of wall tapestries whose beauty brought unstinted praise from the Spanish conquerors. The palaces and temples of the Toltecs and the magnificent new palace of Montezuma II were decorated with these brilliant feather hangings. But all work of whatever class into which the feathers of the quetzal entered was reserved for the use of the king, the nobles, the statues of the gods and the temples. It has been said that the trail of the serpent (the most graphic symbol of the god of the air) is over all Mexico, but wherever the serpent is symbolically present the quetzal is its inseparable

companion. In recognition of the important part played by the quetzal in the religion, history and political life of the cultured races of Mexico and Central America, it has been made the central figure in the modern coat of arms of Guatemala.

The word quetzal seems to have been used in compounds as a contraction for Quetzalcoatl; and the name of one of the Chichimeca rulers is given as Quetzal, which is probably a contraction of his ecclesiastical title as head of the state religion. All accounts of the quetzal represent it as a very shy and retiring bird inhabiting thick forests where it is rarely seen. It is not probable, therefore, that the numerous towns and localities bearing its name should have been named from its presence there. It is more likely that in each of the places so named there was a shrine of the air god, Quetzalcoatl. The presence of names beginning with quetzal far down into Guatemala is an evidence of Nahua culture in these regions and would seem to indicate the subjection of them by the Aztecs or other Nahua races since almost always the compound name beginning with quetzal is Nahuatl. Thus Quetzalpan is "place of the quetzal"; Quetzalteuhtli "the Lord Quetzal"; Quetzalatl, the "Quetzal River" or water; Quetzalpopoca, the "place of the smoky quetzal"; Quetzaltepec, the "hill of the Quetzal"; Quetzalxochitzin, composed of quetzal, xochitl (flower), tzin (princess), the "Quetzal—Flour—Princess"; the full name of Xochitl, the traditional discoverer of pulque, the national drink of Mexico. It would seem that among the collection of birds in the royal aviary or breeding place of Montezuma II in Mexico City, the quetzal was successfully raised. See TROGON; QUETZALCOATL.

QUETZALCOATL, kâ-tzâl-kwâtl, the Mexican "Fair God," is a nature deity transformed into a great national god and the founder of a priesthood. As he is a primitive deity the legendary lore connected with him assumes many forms. He is the god of the winds who, driving the clouds before him, causes the moisture to descend upon the earth. He thus becomes the deity of the beneficial influence of the air, of medicines and of the healing art. These functions and attributes made him the god of fertility. As originally all wealth came from the fertility of the soil Quetzalcoatl became the god of wealth and of all activities that produce wealth or increase it. Thus he became the patron of artisans, farmers, planters, gardeners and workers of the soil generally, of stone engravers, cutters and builders and of gold and silversmiths and other workers in metals. Like the wind gods of other countries, he was the patron of music and the messenger of the higher gods. He was the supreme culture deity of the Toltecs and as such the revealer of all learning and the inventor and introducer of the useful arts, among them, the invention of writing and the making of books. He organized the religious ceremonies and rituals of the Toltecs and revealed to them the knowledge of astronomy and astrology. To him barren women prayed that they might be blessed with children and the agriculturist beseeched him that he might look with favor upon his fields. He it was who swept the sky clean for the coming of the

tlaloques or rain gods. He was the patron of hunters, messengers, runners and of sports, and a temple devoted to his worship was always found at the entrance to the Aztec and Maya gymnasiums or courts where the native ball games were held. He was called the "Cloud Pusher" because, in his capacity as the wind, he drove them before him; as the bestower of all wealth he was the god of gaming and for the same reason thieves prayed to him, and under various epithets, he was the deity of fishermen. He made the winds to blow and he calmed them, and for this reason he was invoked in periods of storm or of prolonged calm. He divided the year into seasons, invented the calendar and named the mountains, lakes, capes, bays, rivers and other prominent features of nature. He was the special patron of feather work, painting and sculpture, and all buried treasure, demented people and travelers were under his special protection. In some of the legends he is represented as the creator of the first man. All these attributes caused him to be looked upon as the special bestower of happiness. He was called Ehecatl, the personified air; Yolcuatl, the rattlesnake; Tohil, the rumbler, and Huemac, he of the big or strong hands (probably significant of his protection of the building and mechanical arts). He was addressed as lord of the four winds, lord of the eastern light, son of the White Cloud, serpent and the Morning Star. The most beautiful of singing birds accompanied him, and when he walked he shook fire from his sandals (emblematic of the lightning), and it thus became the property of mankind.

Quetzalcoatl was the tribal god of the Toltecs. He and Huilzilopochtli, the Aztec war god, Tezcatlipoca, the Texcocan tribal deity, and Camaxtli, the Tlaxcalteca tribal divinity were popularly thought by the Aztecs to have been brothers, and there is good reason to believe that they were all tribal variants of the same mythological culture hero and god of the wind. The Tlaxcalans satisfied their own local pride by representing Quetzalcoatl to be the son of Camaxtli. The Otomi identified him with their god of hunting who seems to have been their supreme deity. Quetzalcoatl has been identified by later investigators with almost every nature deity, yet the earlier writers show that the natives regarded him as a wind god or the chief of the wind gods and the presiding deity of the air, and as such he was symbolized by the quetzal or royal bird, the cloud symbol; the snake, emblematic of the whirling wind; the flint, the material sign of the thunderbolt, and the cross, emblematic of the four regions of the earth from which came the four winds, and in a secondary sense, symbolical of his connection with the deities of moisture and the gods of fertility. Quetzalcoatl was active before the creation of man in which he seems to have taken a prominent part. Sahagun says that to him was assigned the task of sacrificing the other primal gods at Teotihuacan, on the occasion of the creation of the sun. This places him very far back in the antiquity of legendary lore. By the Toltecs and the Aztecs alike he was regarded as one of the oldest of the gods. At Tula his worship was developed to a high degree of ritual and ceremony, and it would seem that the Toltec sovereign was his repre-

sentative upon earth and as such known as the Quetzalcoatl, a name used only in his religious capacity, and which must, therefore, be regarded simply as a title, since the king used his state name for all relationships outside the pontifical. This has caused a great deal of confusion, which began among the Toltecs and Aztecs themselves who represented the god as coming to the earth from the bright land of the sun and the mythical Tlapallan and teaching the people all the arts and sciences. This myth was elaborated by the ruling class who, as his representative, claimed descent from him. Thus the kings of Tula are sometimes known by their pontifical and sometimes by their executive names, as the story related was supposed, by the narrator, to be ecclesiastical or secular.

According to the myth, Quetzalcoatl appeared in the east from over the sea with a body of priestly attendants and made his way to the uplands of Mexico where tradition credits him with having preached the doctrines of peace in the Toltec capital of Tula, from which he was driven out by the wiles of Tezcatlipoca, god of the night winds. From Tula he went to Cholula where he remained 20 years teaching the arts and sciences and preaching peace. From Cholula he went to Coat-zacoalcos (Puerto Mexico), from whence he sailed eastward back to Tlapallan on a raft or boat of serpents. He left behind him four of his most trusted followers who were commissioned by him to divide the land of Cholula among them and to rule it in his stead, they and their descendants, until his promised return. The return of Quetzalcoatl was firmly believed in by Toltecs, Aztecs, Zapotecas and Mixtecas alike, and on the appearance of the Spaniards off the coast of Mexico, the belief was general that they were the Fair God and his attendants come back to claim the sovereignty of the land. This belief prevented the superstitious Moctezuma II from taking energetic measures against the conqueror, Cortés, and aided the latter very materially in his conquest of the Aztec empire.

The worship of Quetzalcoatl, under various names having the same signification, was common in Yucatan, Oaxaca, Chiapas and Guatemala where magnificent temples were erected to him. There his cult shaped and ennobled the architecture of pre-Columbian days as nowhere else in America. Everywhere throughout this land is the trail of the "plumed serpent," his most characteristic sign and a literal rendering into English of his name. QUEUE ROUGE, kē roozh, a West Indian name for a large spider much dreaded by the Negros. See LATRODECTUS.

QUEVEDO Y VILLEGAS, kā-vā'thō ē vēl-yā'gās, Don Francisco de, Spanish author: b. Madrid, 26 Sept. 1580; d. Villanueva de los Infantes, 8 Sept. 1645. After study at the University of Alcalá, he was banished the country for having killed a nobleman in a duel and went to Sicily, where he entered the service of the viceroy, the Duke of Osuna, by whom he was later made Minister of Finance in the administration of Naples. After his return to Spain he was arrested in 1639 on suspicion of having written some satiric verses against the king and ministry and subjected to a four years' imprisonment, the rigors of which caused his death. He is best known for his prose satires, such as 'Historia y vida del Beescón, El gran Tacaño' (1626), and 'Los Suenos,' 'Visions' (1635). The latter were rendered into English by Sir Roger L'Estrange in 1708. There is a Spanish edition of his works by Guerra y Orbe (1852). His prose has been published in 'Biblioteca de autores españoles' (Vols. XXIII and XLVIII); his verse, in Vol. LXIX. (See LOS SUENOS). Consult the study by Mérimée (1886).

QUEZALTENANGO, kā-sāl-tā-nān'gō, or **QUESALTENANGO**, Guatemala, city, capital of a department of the same name, the second city of the republic in size and in importance, 80 miles west of Guatemala City, at an altitude of 7,500 feet above sea-level. The town is well-built with wide and well-paved streets; among its handsome public buildings are the cathedral, city hall and penitentiary. It has a considerable domestic trade and manufactures of cotton and woolen textiles. A railway about 50 miles long connects Quezaltenango with Champerico on the Pacific Coast. The city was founded in 1524 by Spaniards, on the site of a native city; there are numerous interesting antiquities in the neighborhood. An earthquake destroyed the town in 1902, but it was rebuilt. Pop. about 30,000.

QUIAÑGAN, kē-āng-ān', Philippines, a former Spanish commandancia, bounded on the north by Bontoc, now a part of the province of Lepanto; area, 64 square miles. Pop. 30,000.

QUIANGANES, kē-āng-ān'ās, a tribe of the Philippines, living in the commandancia of Quiañgan, province of Lepanto, Luzon. They belong to the Ifugas linguistic stock and are a headhunting people.

QUIBDO, kēb'dō, Colombia, town in the department of Cauca, formerly the capital of the ancient province of Choco, on the Atrato River, about 30 miles from the Pacific and 200 miles northwest of Bogotá. It was of considerable commercial importance when the gold mines of the vicinity were being worked; but the majority of the mines are now abandoned owing to lack of use of modern methods of mining. The surface gold exists now only in small quantities. Pop. about 15,800.

QUIBERON, kē-brōn, France, town, in the department of Morbihan, on the Bay of Quiberon, on a peninsula, about 22 miles southwest of Vannes. Nearby and on the peninsula are the noted megalithic monuments of Carnac (q.v.). Quiberon is now only a small fishing

town; but it is of historical interest on account of the unsuccessful attempt of an English force to land here, in 1746, at the time of the Seven Years' War. On 20 Nov. 1759 Admiral Hawke attacked and overcame a French fleet under Admiral Conflans in Quiberon Bay, near the town. On 27 June 1795 a body of about 1,400 of French emigrant royalists landed here from an English fleet and tried to arouse the people of La Vendée and Brittany against the Convention. They were repulsed by a force under General Hoche, some returned to their ships, and those who were taken prisoners were shot. Pop. about 3,500.

QUICHÉ, ke-cha', or **KICHÉ**, an ancient nation of western Guatemala, the people of which were civilized and of the Mayan stock. Their language was a dialect allied to that spoken by the Cakchiquel. Their extant chronicles begin with the 8th century. In their sacred book, 'Popol Vuh,' an account is given of the life of their great culture hero, Xbalanque. This book gives many of the national traditions, written in the Quiché dialect. The first part of the book contains mythological accounts of their history, people, events, etc.; the second part is a detailed history of the origin of the tribe and some account of the Cakchiquel. The descendants of the Quiché now inhabit a large region in the central and western part of Guatemala. Consult Ximenez's Spanish translation of 'Popol Vuh' (Vienna 1857); Abbé Brasseur de Bourbourg's French translation of 'Popol Vuh' (Paris 1861).

QUICHUA, kē-choo'a, a very extensive South American Indian family composed of many tribes linguistically closely related. The Quichuas inhabit Peru and parts of Ecuador and Bolivia and neighboring territory, and their language is quite similar in grammatical structure and vocabulary to that of the Aymara who, with them, formed the greater part of the ancient Inca Empire. There seems to be some reason to believe that the Quichua, though linguistically one, was composed of the union of several races in the course of the many centuries of evolution which produced the various successive civilizations of Peru, Ecuador and Bolivia and probably the uplands of Colombia. The Quichua tongue, which was formerly the state language of the Incas, is still the chief speech of the Indian population of Peru, especially in the mountainous districts; and it is also still extensively spoken, under the same conditions, in Bolivia and in parts of Ecuador and the north of Argentina. The viceroy, Toledo, writing in 1575, after nearly half a century of civil war and Spanish conquest had frightfully decimated the Quichuas, estimated that the population of Peru, which was still very largely native, was 8,000,000. This estimate, which is probably conservative, does not include the wild Indian tribes in the mountainous districts which had still partially or wholly maintained their independence, nor the vast Quichua population of territory adjoining Peru. That the Quichuas were once a very numerous people is attested by their archæological remains, by the evidence of eye-witnesses of their land and culture at the time of the Spanish conquest and by the thousands of now deserted "andens" or terraced fields on the mountain slopes in the Andine regions, many of which

are situated at an elevation of 12,000 feet, and some even considerably higher.

The civilization of the Quichuas ranks among the highest produced by the aborigines of the American continents. Its architecture was not the equal of that of Mayas, Quiches and other cultured races of Mexico and Central America, but its political organization seems to have been much better and its social life and government superior. Its religious ideas and ecclesiastical system were purer, more civilized and humane, and its system of government highways were vastly superior to anything else in the same line in the New World at the time of its discovery; and they were built on a much more extensive scale than anything then existing in Europe. Quichua was the name given by Friar Domingo de San Tomás, the first European who studied it grammatically. But Quichua was only one of many dialects of one great tongue. It was, however, one of the most important of the Quichua linguistic divisions. This ancient language of the Incas is a noble tongue fitted for all the needs of a highly developed civilization. It is flexible, has an extensive vocabulary rich in plural forms and verbal conjugations, the power of forming compound nouns and, above all, in synonyms. It has the power to express intricate abstract ideas and relationships and to record poetical and rhetorical conceptions and imagery. There seems to be no doubt that the Quichuas possessed an oral literature and drama at the time of the conquest. The latter was continued, for some considerable time after the downfall of the native dynasty, by the Indians. On several occasions their dramatic performances were officially prohibited throughout Peru. One of these, 'Ollantay,' which depicts events in the time of one of the native rulers, has survived in an interesting, if somewhat mutilated form.

Quichua Culture.—The Quichuas were an artistic race in the pre-Columbian days and they were famous workers in metals, designers, builders, weavers, orators, law-makers and traders. They are supposed to have carried their commerce for thousands of miles, throughout their own vast empire, and far to the north of it, into neighboring countries. They were probably further advanced in the knowledge of medicinal plants than any other American people and less given to superstitious practices in connection with their uses. The Quichuas developed a very complicated system of keeping account by means of knotted strings of different colors which excited the wonder and admiration of the Spaniards. It has been asserted, on what seems very good authority, that these "quipus" were made use of by the Peruvians to record their history and traditions as the American Indians of the eastern States used their wampum belts, though with much more accuracy and extended application.

In the land of the Incas, which seems to have been run on a curious combination of absolutism and socialism, every able-bodied person was expected to work, and the proper distribution of wealth was carefully looked after by the emperor, who was termed "the friend of the poor"; so that, we are told, the land was enormously wealthy, and Cuzco, the capital, was the richest of all the aboriginal American cities.

The Quichua Empire was divided into four quarters (corresponding to the four cardinal

points) by lines radiating from Cuzco; and the whole, known as the four United Provinces, was governed by viceroys, through whom the emperor kept his hand upon the reins of government throughout his vast domains. A system of division and subdivision, with responsibility to the next highest immediate authority, made the government of the whole country and the control of it by the emperor wonderfully effective. Each "cunca" of 10 families formed a community and at the same time the unit of government. Thus a most scientifically worked-out feudal system placed the responsibility, in every case, where it belonged and maintained it there. This system of supervision permitted the Inca government to organize all the resources and facilities of the empire; and the result was that not a spot capable of cultivation was neglected. Terraces were built on the sides of the mountains, from the foothills to the cold regions of the limit of vegetation, some of these upper terraces being not more than a yard wide. Irrigation was made a science. Canals starting at the snow-line carried the water down the mountain side from one terrace to another, while more extensive irrigation works brought the arid lands of the coast under subjection and rendered the pasture lands fertile. Even the flow of water was regulated by the government to the extent, altitude and nature of the land to be irrigated. Vast herds of llamas and alpacas supplied meat and the finest of wool for the whole nation; as did also the wild huanacus and vicuñas. The Inca government also looked after the distribution of the population and saw that the people were placed where they could most easily make a living and contribute to the growth and greatness of the empire. See PERU.

R., 'The Inca Civilization in Peru' (1889); Molona, Cristóbal de, 'The Fables and Rites of the Incas' (Markham's translation, 1873); Montesinos, Fernando, 'Memorias antiguas del Peru' (Jiménez de la Espada edition, 1882); Prescott, 'Conquest of Peru'; Robertson, 'History of America'; Santillan, Fernando de, 'Relacion' (published in 1879); Valera, Blas, 'Institutions of the Incas' (fragmentary, 16th century); Vega, Garcilasso de la (Inca), 'Commentarios Reales' (1607); Zarate, Augustin de, 'Provincia del Peru' (1551).

QUICK, Sir John, Australian statesman and author: b. Saint Ives, Cornwall, England, 14 April 1852. He was taken to Australia by his parents in 1854 and was educated there. At the age of 15 he became a compositor on a local paper, where he successfully tried his hand at literary work. He worked on several daily papers and continued his studies at the University of Melbourne from which he was graduated in arts in 1877 and in law the following year. Two years later he was elected to Parliament where he became a prominent advocate of Australian federation. He was a member of the convention which framed the constitution of the commonwealth (1897-98) and chairman of the tariff commission (1905). He had al-

ready been knighted in 1901 for federal services, and was postmaster-general of the commonwealth (1909-10). A recognized authority on constitutional law, he has written the 'History of Land Tenure in Victoria' (1893); 'Parliamentary Government in Victoria' (1894); 'A Digest of Federal Constitutions' (1896); 'The Federal Constitution Explained' (1898); 'Annotation of the Constitution of the Australian Commonwealth' (1901); 'Judicial Power of the Commonwealth' (1904); 'Imperial Unity and How to Promote It' (1908); 'Workers' Compensation Act' (1915).

QUICK-SAND, a tract of loose sand mixed with water which will not support heavy bodies. In appearance quick-sands do not differ from the adjacent sands. They usually occur on flat shores underlain by stiff clay or other impervious materials and especially near the mouths of large rivers. They appear to be formed by the continued collection of water within the sand bank which is prevented from running off by the underlying impervious layer. The water which infiltrates the sand may be supplied, either by a river current, directed against the concave shore or spreading over a sea-beach; by tides which at their ebb leave behind them imprisoned bodies of water; or by sea-currents running through narrow channels and forcing the water against the adjacent shore. The grains of quick-sand have rounded surfaces, as distinguished from angular or "sharp" sand. It is, moreover, of very light weight. The infiltrated water separates and lubricates the particles, rendering them unstable and unable to support a heavy weight, such as the body of a man. They have obtained a great reputation for treachery and danger, especially because they cannot be distinguished at sight. The subject has been drawn upon considerably in literature, notably in Hugo's 'Toilers of the Sea,' in Wilkie Collins' 'Moonstone' and in the 'Bride of Lammermoor,' with probably some exaggeration of the danger. The effect of quick-sands, however, is well illustrated by the sinking in 1875 of a locomotive and train at Pueblo, Colo., which sank beyond discovery though probed for to a depth of 50 feet. To make it possible to operate in quick-sands engineers are accustomed to congeal them by forcing into them brines and liquids at low temperatures.

QUICKSILVER. See **MERCURY** OR **QUICK-SILVER**.

QUIDDE, Ludwig, German writer on mediæval history and modern politics: b. Bremen, 23 March 1858. He became a professor at the University of Munich, a member of the Bavarian Landtag and the board of aldermen of the capital of the kingdom. He edited a series of publications of German imperial documents of the 15th century and attained a widespread sensational reputation by the publication, in 1894, of a work called 'Caligula,' ostensibly a biography of the dissolute Roman emperor, but actually a neatly veiled presentation of the foibles of Emperor William II of Germany. The book passed through 30 editions in one year, which, as it was an historical work, was enough to attract the attention of the public prosecutor. Quidde was brought up for trial, but defended himself so ably that he was acquitted. On being asked by the prosecuting

attorney whom he had had in mind during the composition of his work, he answered, "Caligula, of course," and confused the prosecutor by asking "Whom have you in mind?" Other works are 'Der schwäbisch-rheinische Städtebund im Jahre 1384' (1884); 'Militarismus' (1893); 'Wetterleuchten der Reaktion' (1895); 'Bayerische Steuerreform' (1909).

QUIDOR, John, American painter: b. Gloucester County, N. J., 1800; d. 1881. He removed to New York in 1826 and studied painting under John Wesley Jarvis and Henry Inman. While his work showed great cleverness he failed to gain recognition in his lifetime and earned a livelihood by painting fire engines and panels for coaches. He excelled in fanciful subjects with a landscape background. His best-known work, now recognized as evidencing fine talent, illustrated scenes from the works of Washington Irving, whom he knew personally. His 'Rip Van Winkle' is considered an excellent piece of work. Other paintings, also from Irving's works, and now in the Brooklyn Institute, are 'Dancing on the Battery'; 'Peter Stuyvesant's Wall Street Tale' (1864); 'Voyage from Communipaw to Hell Gate' (1866); 'Voyage of the Good Olaf Up the Hudson' (1866).

QUIDS, in American political history, a name applied to a faction of the Republican party led by John Randolph from 1805 to 1811. They were opposed to the nomination of Madison, Jefferson's choice for the succession. They declared war on the administration party in 1806, as governing Congress by backstairs influence. They opposed the restrictive system and nominated Monroe in 1808. Their leading ground of divergence from the administration was that it had moved away from the ground occupied by the party when in opposition, and in the direction of centralization and Federal encroachment. The name is derived from "tertium quid" and signifies their separation from both parties.

QUIETISM, a tendency in religious devotion rather than any specific system of religion or mysticism. It consists in making Christian perfection a state of uninterrupted contemplation of divine things, the soul meanwhile remaining quiet and entirely passive under the divine influence, heedless of the customary precepts of practical religion, and without thought of rewards or punishments in another world, which are the master motives of vulgar piety. The term Quietism was first used to designate the mystical teaching of Miguel de Molinos (q.v.) who died (1696) in the prison of the Holy Office at Rome to which he had been condemned for teaching in sundry of his writings that the perfect Christian life consists in passive contemplation, unaffected by hopes or desires, and that the soul thus occupied neither gains by good works or acts of piety, nor suffers through the commission even of gross sins, for these affect only the lower nature of the devotee and cannot bring any strain upon the purity of a contemplative soul. The amiable Fénelon (q.v.) was won over to hearty acceptance of some of the less objectionable features of Quietism by the influence of his disciple Madame Guyon (q.v.), several of whose mystical writings he approved and defended when

they were condemned by the Gallican church authorities, among them Bossuet, bishop of Meaux, who declared them to be a "mass of extravagances, illusions, and puerilities." Fénelon's published apology for the doctrines of Madame Guyon having been censured at Rome as containing propositions rash, scandalous, etc., he promptly bowed to the judgment of the Holy See, publicly committing his own book to the flames. Consult Heppe, H., 'Geschichte der quietistischen Mystik' (Berlin 1875).

QUIETISTS. See QUIETISM.

QUIGLEY, James Edward, American Roman Catholic prelate: b. Oshawa, Ontario, Canada, 15 Oct. 1854. He was graduated from Saint Joseph's College, Buffalo, N. Y., in 1872. He then began his theological studies at the Vicentian Seminary, Niagara, N. Y., now Niagara University, and continued them at the University of Innsbruck, Austria, completing his entire course at the Propaganda, Rome, where, in 1879, he obtained the degree of doctor of theology, and was ordained priest 13 April of the same year. Returning to the United States, he was appointed pastor of the Church at Attica, Wyoming County, N. Y., and in 1884 was named rector of the Cathedral, Buffalo, N. Y. In 1896 he asked to be transferred to the rectorship of Saint Bridget's Church, Buffalo, made vacant by the death of Monsignor Gleason, but his residence in that parish was short, as, on 24 Feb. 1897, he was consecrated bishop of Buffalo to succeed Bishop Ryan, deceased. Bishop Quigley was chosen arbitrator in the great labor strike in Buffalo during 1904, and on 8 Jan. 1903 was promoted to the archiepiscopal see of Chicago. The archdiocese comprises a Catholic population of approximately 1,000,000; 619 priests; 316 churches; 168 parochial schools; 7 orphan asylums; 18 hospitals and many other charitable and educational institutions.

QUILL, the hollow stem of a feather (see PLUMAGE). Many utilities have been found for those of the larger size, but their use is declining. The principal use of quills is still for making pens, for which the feathers of the swan are most highly esteemed, but goose-quills are most commonly used. Crow-quills are said to be best for fine writing and drawing. In preparing quills for making into pens, they must first be cleaned inside and outside of fatty matter, which would prevent the ink from flowing freely. This is done by burying the quill-ends of the feathers for a few seconds in fine sand at a temperature of about 140° F. The quills are then polished and dried.

QUILLAIA (kwil-lā'yā) **BARK**, the bark of a South American tree (*Quillaja saponaria*), belonging to the division *Spraea* of the order *Rosaceae*. The tree has smooth, oval leaves, and white terminal flowers, solitary or in small clusters.

QUILLER-COUCH, kwil'er kooch, **SIR** Arthur Thomas, English author: b. Cornwall, 21 Nov. 1863. He was educated at Oxford, where he was classical lecturer in 1886-87, and won some success with his first book, 'Dead Man's Rock' (1887). In 1887 he began a literary career in London, where in 1889 he joined the staff of the *Speaker*, the Liberal weekly newly established by Sir Wemyss Reid.

He was knighted in 1910, and succeeded to the professorship of English literature at Cambridge in 1912. He retained until 1899 his connection with the *Speaker*, a part of his contributions to which appear in the collections of short stories, 'Noughts and Crosses' (1891) and 'The Delectable Duchy' (1893). Among his further volumes are 'Green Bays: Verses and Parodies' (1893); 'The Golden Pomp' (1895), an Elizabethan anthology; 'Ia' (1896); 'Adventures in Criticism' (1896); being selected reviews; 'The Ship of Stars' (1899); 'Old Fires and Profitable Ghosts' (1900); 'The Laird's Luck' (1901); 'The Westcotes' (1902); 'The White Wolf' (1902); 'The Adventures of Harry Revel' (1903); 'Hatty Wesley' (1903) and 'Shining Ferry' (1905); 'Shakespeare's Christmas' (1906); 'From a Cornish Window' (1906); 'Poison Island' (1907); 'Major Vigoreux' (1907); 'True Tilda' (1909); 'Lady Good-for-Nothing'; 'Corporal Sam and Other Stories' (1910); 'Hocken and Hemken' (1912); 'Nicky Nan, Reservist' (1915); 'On the Art of Writing' (1916); 'Memoir of Arthur John Butler' (1917). He published also three anthologies of English verse, which are marked by the finest appreciation of lyric quality. His style is vivid, his humor subtle and poignant and his imagination vigorous and colorful. These qualities gained him the commission to complete the novel 'St. Ives,' left unfinished by Robert Louis Stevenson (q.v.). His earlier work appeared over the pseudonym "Q." Much of his material he has derived from Cornwall, where he has made particular study of the Welsh poor.

QUILP, kwilp, a malicious and hideous dwarf who figures prominently in Charles Dickens' novel, 'Old Curiosity Shop.' He torments and abuses his wife Betsey, and when about to be arrested for felony drowns himself.

QUIMBY, kwim'bī, **Phineas Parkhurst**, American mental healer: b. Lebanon, N. H., 16 Feb. 1802; d. Belfast, Me., 16 Jan. 1866. In 1838 his interest in hypnotism was awakened through a series of lectures given in Belfast by a Dr. Collyer. He made a special study of the subject and afterward traveled through Maine and New Brunswick giving exhibitions of mesmerism. His interest was then aroused in the relation of mesmerism and healing and he thereafter devoted himself to mental healing, although he later dispensed with mesmerism as unnecessary in the diagnosis and mental cure of disease. In 1859 he opened offices in Portland, Me., although retaining his residence in Belfast. Mrs. Mary Baker G. Eddy, then Mrs. Patterson, was one of his patients in 1862, but always disclaimed being influenced by him in the foundation of the cult of Christian Science. In an article written by Quimby in 1863 he uses the term "Christian Science," and one of his patients, a Dr. Evans, made repeated use of the term "mental science" in articles written in 1869. Quimby's influence in this field in the middle of the 19th century was considerable. Consult Dresser, A. G., 'The Philosophy of P. P. Quimby' (1895).

QUIMPER, kân pār', France, sometimes called **QUIMPER-CORENTIN**, capital city of the department of Finistère, lying at the junction of the Steir and Odet, whence the name from

Breton ('Kemper,' junction or confluence. It has the fine cathedral of Saint Corentin, built in 1424, and two churches — one, that of Locmaira dating from the 11th century; the other, Saint Mathieu, dating from the 16th. The old capital of Cornouailles, it figured in the religious wars. It has sardine-fisheries, breweries, paper factories, tanneries and a population of about 20,000.

QUIN, kwin, James, English actor: b. London, 24 Feb. 1693; d. Bath, Somerset, 21 Jan. 1766. He was the son of an Irish barrister, and was educated in Dublin. In 1714 he went upon the Dublin stage, and a year after appeared at Drury Lane Theatre. In 1717 he went to the theatre in Lincoln's-Inn-Fields, where he remained 14 years, and acquired celebrity in characters of grave, dignified and sententious tragedy, as in *Cato*, *Zanga* and *Coriolanus* (in Thomson's tragedy of that name), and in those of strong, sarcastic, comic humor, as *Falstaff* and *Volpone*. In 1735 he returned to Drury Lane, on such terms as no actor had previously received; and he retained pre-eminence until the appearance of Garrick in 1741. In 1747 he was engaged at Covent Garden with Garrick; but the new actor obtained so great a share of attention that Quin retired from the regular stage in 1751. His last performance was *Falstaff* (1753), in which character he is supposed never to have been excelled. Garrick, once his rival afterward his friend, wrote the epitaph for his monument in Bath Abbey. Consult Doran, J., *Annals of the English Stage* (3 vols., London 1887).

QUINAULT, kē-nō, Philippe, French dramatist: b. Paris, 3 June 1635; d. there, 26 Nov. 1688. He studied law, but became a playwright, his first dramas '*Les rivaux*'; '*L'Amant indiscret*' being produced when he was 18 and meeting with marked success. The continued success of his tragedies, comedies and tragicomedies, of which he produced 16, made him a mark for the satire of Boileau, and he abandoned tragedy and engaged in writing librettos for the operas of Lulli. In this field he displayed great originality and though his success at the time was attributed to Lulli's music by Boileau and other critics, his verse is still read and admired while the music is forgotten. He was admitted to the French Academy in 1670 and his later years were spent in ease and comfort. Of his operatic pieces '*Armide*' and '*Atys*' are best known and of his dramas '*Astarte*' (1663) and '*La Mère Coquette*' (1665). Editions of his works were published in 1739, 1842 and 1880. Consult Richter, E., '*Philippe Quinault*' (Leipzig 1910).

QUINCE, a shrub or small tree (*Cydonia vulgaris*) of the rose family; a native of central and eastern Asia, where it was cultivated more than 2,000 years ago and whence it has been introduced into all cool temperate countries of the civilized world. It is a close relative of the apple and pear, with which trees some botanists class it, but from which it is distinguished by having its flowers solitary upon the ends of twigs of the present season's growth. The popularity of the quince is limited because it is inedible in the fresh state, but it is highly prized for making preserves, jellies, etc., and as a flavoring for mixing with other fruits.

The plant is propagated mainly by stool layering, the rooted layers being grown in nursery rows usually two years after their removal from the parent bush. They are then planted from 10 to 15 or more feet apart, the distance depending upon the soil. On light soils the shrubs make rapid growth but are shorter lived and less productive than upon heavy. They should commence to bear when about three years old and reach full bearing when 10. Contrary to popular opinion the quince will do best when cultivated, but the stirring of the soil must not be deep because the feeding roots are rather close to the surface, especially if the soil be very moist. To obviate this danger, growers often set the plants rather deeply and for the first few years work the soil away from them so as to induce deep rooting. They always use shallow rooting cover crops. It is another popular misconception that the plants do best in undrained soil. The best orchards of western New York, where the quince is an important crop, are upon well-drained land.

The tree seldom grows more than 15 feet tall. It should be trained in bush form; that is, with several stems, though some growers prefer the tree form with only one stem. The latter seems more likely to be injured by borers. Beyond the removal of interfering, dead or unnecessary limbs the pruning consists of "heading-in" the twigs, a process which reduces the number of fruits. Being fairly hardy and a rather late bloomer the quince is a very regular annual bearer, but unless the tops be kept open and the quantity of fruits reduced the specimens will be inferior. Though the fruits ripen late and when gathered are generally very hard they should be handled very carefully and not be allowed to freeze. Except as indicated the management of a quince orchard is much the same as for pear orchard.

Among the insects which feed upon the quince are several borers, scale insects, caterpillars, plant-lice, etc., which are found on other fruit trees, especially apples and pears. These may be controlled in the same way. (See APPLE; PEAR; INSECTICIDE.) The quince curculio (*Conotrachelus crataegi*), a broad-shouldered snout-beetle of American nativity, lays its eggs in the fruit in early summer. It may be controlled like its relative the plum curculio. (See PLUM.) Several so-called plant diseases common to the pear and apple are sometimes reported upon the quince. They have been combated in the same way as on the other fruits. Consult Bailey, '*Cyclopedia of American Horticulture*' (New York 1900-02); Meech, '*Quince Culture*' (New York 1896).

QUINCKE, Georg Hermann, German physicist: b. Frankfort-on-the-Oder 1834. He was educated at the universities of Berlin, Königsberg and Heidelberg, and in 1859 was privatdocent at the University of Berlin. In 1872 he was appointed to a chair at the University of Würzburg, and in 1875 became professor of physics at Heidelberg. He has made important investigations of capillary phenomena, and valuable researches respecting electric influence upon different forms of matter. He was created D.C.L. by Oxford, LL.D. by Cambridge and became honorary Fellow of the Royal Society of London. Besides his contributions to physics and other sciences, he wrote '*Ge-*

schichte des physicalischen Instituts der Universität Heidelberg' (1885).

QUINCUNX, an arrangement of five objects in a square, one at each corner and one in the middle. It is particularly employed in reference to the arrangement of trees. The term is frequently used in astronomy.

QUINCY, kăn-sē, **Antoine Chrysostome Ouatremère de**. See **QUATREMÈRE DE QUINCY**, **ANTOINE CHRYSOSTOME**.

QUINCY, kwîn'zi, **Edmund**, American author, son of Josiah Quincy (1772-1864): b. Boston, Mass., 1 Feb. 1808; d. Dedham, Mass., 17 May 1877. He was graduated from Harvard in 1827, was a prominent and able contributor to the anti-slavery press and wrote 'Wensley' (1854); 'Life of Josiah Quincy' (1867); 'The Haunted Adjutant and Other Stories' (1885) and edited 'Congressional Speeches' (1874).

QUINCY, Josiah, sometimes called **JOSIAH QUINCY, JR.**, American lawyer: b. Boston, Mass., 23 Jan. 1744; d. at sea off Gloucester, Mass., 26 April 1775. He was graduated from Harvard in 1763, studied law in the office of Oxenbridge Thacher and acquired a large practice. After the "Boston Massacre" (q.v.), he was selected with John Adams, by Captain Preston as counsel for the defense. He wrote many political pamphlets and contributed much to contemporary journals. In 1774 he sailed for England, where he consulted with the friends of America, but died on the return voyage. An able orator, he was among the first to assume a bold revolutionary attitude. Though he incurred at the time some odium for his defense of Parker, his course was later strongly commended. His 'Life' was published by his son Josiah (q.v.).

QUINCY, Josiah, American statesman and educator: b. Boston, 4 Feb. 1772; d. Quincy, Mass., 1 July 1864. He was graduated from Harvard in 1790, studied law and in 1793 was admitted to practice, and gave much study to political problems. By his oration in Old South 4 July 1798, he gained so extended a reputation that in 1800 he was made Federalist candidate for representative in Congress. Though defeated then through the ridicule of Republican journals, he was elected in the autumn of 1804 after having in the spring of that year been chosen to the State senate. He remained in Congress until 1812, when he declined re-election. He was a finished orator, spoke boldly on many difficult topics of debate, and was one of the most efficient members of his party, which during his whole term of service remained hopelessly in the minority. His statesman-like grasp of affairs is most clearly shown by the constant emphasis which he placed upon the increasing political danger with which the Union was menaced by the slave power. He feared civil war, and preferred a peaceable secession—a course not then seen, as it was later, to be impossible. In the State senate he urged Massachusetts to suggest to Congress an amendment of the Constitution, by which the clause permitting slave States to reckon three-fifths of the slave population in obtaining a basis for representation was to be stricken out. Of course, such a measure, had it succeeded, would have resulted in the dismemberment of the Union. Quincy opposed the annexation of the Louisiana territory, and in his speech of 4 Jan. 1811 took

the advanced Federalist position that the Constitution did not confer on Congress power to admit any new States save such as might be formed from territory belonging to the United States in 1787. He declared that, if the bill passed, the Union was thereby dissolved, and that it would be the right of all States and the duty of some "to prepare definitely for a separation." This is believed to be the earliest enunciation in Congress of the doctrine of secession. Eventually Quincy acquiesced in the purchase, upon each of the original 13 States signifying its assent. He attacked the Embargo, and opposed the War of 1812, though unlike many Federalists, he supported the administration, and on 25 Jan. 1812 made in the House a notable speech on the navy. Upon his retirement from Congress in 1813, he was at once elected to the State senate, where he remained until 1820, then entering the House of Representatives, of which he was speaker until his resignation in 1822 to become judge of the Boston Municipal Court. In this capacity he was the first to hand down the ruling then much criticized but now accepted in the United States and England, that the publication of truth with good intent and for a justifiable end is not libel. From 1823 to 1828 he was second mayor of Boston; during his administration all the municipal departments were put in efficient working order. In 1829 he became president of Harvard, and this post he held until his retirement in 1845. In 1856 he was a supporter of Fremont for the presidency. Besides several speeches, he published 'History of Harvard University' (1840); 'History of the Boston Athenæum' (1851); 'The Municipal History of Boston' (1852); 'Memoir of John Quincy Adams' (1858) and other works. Lowell refers to him as "a figure of admirable example in a democracy as that of a model citizen." Consult Quincy, 'Memoir' (1867); Lowell, 'A Great Public Character' in 'My Study Windows' (1867).

QUINCY, Josiah, American lawyer, son of Josiah Quincy (1772-1864): b. Boston, Mass., 17 Jan. 1802; d. Quincy, Mass., 2 Nov. 1882. He was graduated from Harvard in 1821, served as president of the Massachusetts senate in 1842, was mayor of Boston in 1845-49 and wrote 'Figures of the Past' (1882).

QUINCY, Josiah, American politician, son of Josiah Phillips Quincy: b. Quincy, Mass., 15 Oct. 1859. He was graduated from Harvard in 1880 and was admitted to the bar but never practised. He has been a leading member of the Democratic party, was chairman of that party's State committee and manager of the literary bureau of the National Committee in 1892. He served four years in the Massachusetts legislature and in 1893 was appointed Assistant Secretary of State by President Cleveland, serving six months. In 1895 he was elected mayor of Boston and in 1897 re-elected, his progressive policy in regard to the extension of municipal functions attracting wide attention. He established the department of municipal statistics, a municipal printing-office and electrical construction department, greatly increased the number of public baths and provided public lectures and concerts and organized eight unpaid commissions to have charge of the city's charitable institutions, public baths and other improvements.

QUINCY, Fla., city and county-seat of Gadsden, 24 miles northwest of Tallahassee, on the Seaboard Air Line and the Georgia, Florida and Alabama railroads. It is situated near the northern border of the State in a productive cotton and tobacco district and there are also large deposits of fuller's earth; the town has a considerable trade in these products. Pop. 3,304.

QUINCY, Ill., city, capital of Adams County, on the east bank of the Mississippi River, 263 miles south of Chicago and 142 miles north of Saint Louis. It is built on an elevated plateau 160 feet above the high-water mark of the river. The trade of the city is extensive and is distributed on seven lines of railroad and the Mississippi River. The commercial interests of Quincy are represented by 1,500 firms with a capitalization of over \$15,000,000, embracing almost every kind of industry. Quincy is known particularly as a manufacturing city, there being eight foundries with a capitalization of \$2,000,000; seven machine shops with a capitalization of over \$1,000,000; five carriage manufactories with a capitalization of \$1,000,000; five flour-mills with a capitalization of \$500,000; also the largest steam-governor plant in the world, with a capitalization of \$1,000,000; two breweries with a capitalization of \$1,000,000 and four incubator factories with a capitalization of \$1,000,000. There are also manufactories of furniture, plows, tobacco, organs, soap, files and matches. Many of the streets are traversed by electric railways, the total extent of which is 27 miles, giving access to all the principal business points and parks. The city is divided into seven wards. Of public and charitable buildings, the city contains two hospitals, with a combined capacity of about 300 beds; a free public library and reading room, with 40,000 volumes; 10 asylums and homes and 33 churches, representing about all the denominations found in a community of the size of Quincy. Of public schoolhouses there are 15, having been built at an aggregate cost of \$750,000, with a corps of 163 teachers. The attendance of the public schools number 5,400 children. Besides these there are 12 parochial schools that have an attendance of 2,400 children with an attendance among the three colleges located here that have an attendance estimated at about 1,500. Quincy's Federal building and courthouse are buildings worthy of any city, so is the city hall, Y. M. C. A. building, Masonic Temple, Chamber of Commerce building, State armory, Knights of Columbus building, Labor Temple. Quincy was settled and laid out by John Wood in the year 1821 and to his memory there has been erected a statue in Washington Park. Quincy has a series of 16 nicely located parks situated in different parts of the city connected by a boulevard surrounding the city and in all aggregating 300 acres. This in connection with the Illinois Soldiers' and Sailors' Home, which contains 225 acres, makes ample room for out-door recreation. The Illinois Soldiers' and Sailors' Home, situated upon these beautiful grounds, is complete in every detail and has a capacity for 2,000 veterans and the average attendance is about 1,700. The water supply of Quincy is given from a reservoir with a capacity of 20,000,000 gallons at an elevation

of 229 feet above the city, giving an average pressure of 40 pounds, the water before entering the reservoir being thoroughly filtered, making it absolutely pure. The pumping capacity is supplied by a triple expansion engine of 8,000,000 gallons daily and one compound engine of 4,000,000 gallons capacity daily, the water being filtered by 14 jewel gravity mechanical filters, therefore, insuring the city over its distributing system of 45 miles of water mains, an inexhaustible supply of water as the water is derived from an intake pipe from the channel of the Mississippi River. The city owns the waterworks. The 40 counties within a radius of 75 miles of Quincy, comprise 21,337 square miles; a population of 861,000; 93,600 farms, worth \$1,092,162,000, with annual products worth \$131,700,000. The urban population in these 40 counties is 210,000. The principal agricultural products are wheat, oats, corn, livestock, fruit. The immediate retail trade territory, 13 counties, comprises a population of 300,000. The immediate jobbing territory, Illinois, Iowa and Missouri, comprises a population of 11,000,000. Pop. of Quincy, 36,600.

QUINCY, Mass., city in Norfolk County, on Quincy Bay and on the New York, New Haven and Hartford Railroad. The city includes within its corporate limits several villages; its area is about 16½ square miles, nearly four square miles of which are in public parks. It is bounded on the north by Neponset River and on the south by Fore River. It was settled in 1625 and was first known as Mount Wollaston. About four years later Thomas Morton (q.v.) obtained control of the settlement and established his "New English Canaan," "Merry Mount." His institution of the "May Pole" and other "Idolls" and his manner of living in general, offended the Puritans of Boston and they thought him a dangerous man in the new country. He was arrested by Miles Standish and sent back to England. The place remained a part of Braintree until 1702 when it was incorporated as Quincy, after John Quincy. In 1888 it was chartered as a city.

The first railroad in New England was constructed here in 1826-27; it was two miles long operated by horses and used for carrying stone for building Bunker Hill Monument. There are many places of historic interest in and around Quincy and some of the buildings of Revolutionary days are still in existence. Quincy came into great prominence the last quarter of the 19th century, on account of an educational movement under the leadership of Francis Wayland Parker (q.v.). Many prominent people have lived in Quincy; it was the birthplace of John Adams, John Quincy Adams and John Hancock. The Adamases are buried under the old "Stone Temple."

Quincy is largely a residential suburb of Boston; but the quarrying interests are still of importance. It has also a large ship building plant, machine and tools shops. It has a city hospital, the Woodward Institute for girls; the Adams Academy, a high school, elementary public schools and the Thomas Crane Public Library, which contains about 25,000 volumes. The Metropolitan District System supplies Quincy with water. The government is administered under a revised charter of 1900, which provides for a mayor and council, elected an-

nually. The school board is chosen by popular vote. The mayor appoints the heads of all departments except that of the school board. The council elects the other administrative officials. Pop. about 41,000. Consult Adams, 'Three Episodes of American History'; Hurd, 'History of Norfolk County'; Pattee, 'A History of Old Braintree and Quincy'; Wilson, 'Where American Independence Was Born'; Adams, 'The Centennial Milestone'; Report of United States Commissioner of Education, Vol. I (1902), on the Quincy educational movement; Partridge, 'Quincy Methods.'

QUINET, kē-nā, Edgar, French litterateur: b. Bourg, 17 Feb. 1803; d. Versailles, 27 March 1875. He was educated at the schools of Charolles and Bourg and the Lycée of Lyons. His first publication was 'Tablettes du Juif Errant' (1823), an apology for his abandoning the military career which had been planned for him. A visit to Germany introduced him to Herder's 'Philosophy of the History of Humanity,' which interested him profoundly and gave direction to his life studies. He published a translation with an introductory essay in 1827. Living at Strassburg he met Victor Cousin and Jules Michelet, the latter of whom became his closest friend. In 1829 he was chosen by the French Academy to go to the Morea as philologist attached to a commission of *savants*, and on his return in 1830 published 'De la Grèce moderne et de ses rapports avec l'antiquité.' His republican sympathies were stirred by the revolution in July and his feelings gained expression in political pamphlets. He wrote a remarkable prose poem 'Ahasuerus' (1833) and later two other epics, 'Napoleon' (1836) and 'Prométhée' (1838). His purpose in these three was to represent humanity as general, individual and religious—Ahasuerus, the race; Napoleon, the individual and Prometheus, the martyr. In 1838 he published a reply to Strauss' 'Life of Jesus'; the next year was appointed professor of foreign literature at Lyons and in 1841 became professor of southern literature in the College of France. His Lyons lectures were published under the titles, 'Génie des Religions' (1842) and 'Le christianisme et la Révolution Française.' His lectures delivered at the College of France attacking the Jesuits so aroused public feeling that the government closed his class-room in 1846. His republican opinions became so pronounced and his expression so outspoken that after the *coup d'état* of Louis Napoleon in 1851 he was banished from France. His exile, which lasted until after the fall of the empire in 1870, was fruitful in such works as 'Marnix de Saint-Aldegonde' (1856); 'L'histoire de mes idées' (1858); 'Merlin l'enchanteur' (1860) and the 'Révolution française' (1865). Re-established in Paris, he was elected to the Chamber of Deputies and voted consistently against all monarchical reaction and for the secularization of laws. His last work, 'L'esprit nouveau' (1874), contains an expression of his social, political and intellectual creed. His complete works were published in 30 Vols. (1877-82). Consult his 'Lettres d'exil' (1884); 'Edward Quinet depuis l'exil' (a biography by his widow, 1888-89); Heath, 'Edgar Quinet: His Early Life and Writings' (1881).

QUINGUA, kēng'wā, Philippines, pueblo, province of Bulacá, Luzon; on the Quingua River, seven miles from its mouth; six miles north of the town of Bulacán. It is a road centre and is a health resort for the surrounding provinces because of its pure water. Pop. 8,860.

QUINIDINE, or **CONQUININE** ($C_{20}H_{21}N_3O_2$), an alkaloid found in Calisaya bark (*Cinchona Calisaya*), and in some other varieties of "Peruvian bark." It is prepared from the mixed cinchona alkaloids (quinoidine) by extracting the powder with ether; shaking with dilute sulphuric acid; neutralizing with ammonia; and precipitating with Rochelle salt. The filtrate is then concentrated, decolorized with charcoal, and precipitated with a strong solution of potassium iodide. The crude quinidine hydriodide is then dissolved in alcohol, and precipitated with ammonia; dissolved in dilute acetic acid; precipitated again with ammonia; and finally crystallized from a boiling hot solution in alcohol. It is also prepared from the mother-liquor remaining after the manufacture of quinine. Common soda is added, and the crude quinidine is precipitated. This is then turned into iodide, and the process continues as above described.

In medicine quinidine is known to be a more powerful febrifuge than quinine, being effective in 17 per cent more cases. Its small yield, as compared with quinine, from the bark extract restricts its manufacture and use. See **QUININE**.

QUININE (kwī'nēn or kwī'nin), **QUININA**, or **QUINIA**, a drug ($C_{20}H_{21}N_3O_2$) largely used in the cure of malarial fevers, in which it is regarded as a specific. It is also a valuable tonic. Quinine is one of the five most important of the 21 alkaloids obtained from the bark of the cinchona-tree (Peruvian bark; see **BARK, PERUVIAN**); the others being quinidine, cinchonidine, cinchonine and hydroquinine (q.v.). The curative power of these alkaloids is accurately shown by the report, dated April 1868, of a commission appointed by the British Indian government (Madras) after the suggestion of Clements R. Markham, C.B., F.R.S. Cases of fever numbering 2,472 were treated, and the result showed failures per 1,000 as follows: Quinidine, 6; quinine, 7; cinchonidine, 10; cinchonine, 23. Quinine alkaloid is seldom used, as it is very insoluble (59° F., 1,600 parts water). The salt known as quinine sulphate ($C_{20}H_{21}N_3O_2$) $\cdot$ H₂SO₄ + 7H₂O is generally in use but the acid hydrochloride (also called the "chlorate") is preferred by careful practitioners; and the tannate for children and the more susceptible, in doses two to three times as large.

The average dose of quinine sulphate for adults in the United States is four to five grains every three or four hours beginning a few hours after a paroxysm and continuing until three hours before another is due, when a much larger dose is given. If, as is to be expected, no paroxysm occurs, the treatment is renewed for some hours on the second day, and then again on the ninth day, which completes the cure. In warmer and more fever-ridden countries, twice to three times this amount is given. Quinine is also used with great success as a prophylactic. Since 1902 it has been distributed free by the Italian government in the malarial sections. The preven-

tive amount for adults is five to seven grains of the sulphate per day divided into two doses. Children receive two to three grains daily during the malarial season. As a tonic the best results are obtained by doses of one-half grain of the hydrochloride twice daily. In the administration of quinine it has been repeatedly noticed that toxic symptoms have been developed in some cases; and investigations have shown that in certain conditions both cinchonine and quinine develop poisonous isomeric forms, known as cinchotoxine and quinotoxine. This change takes place in the preparation of quinine when the heating at 212° is prolonged and acetic acid is present. The same changes have been noted at the temperature of the body in the presence of such acids as are sometimes found in the digestive tract, particularly acetic and citric acids. The poisonous symptoms are sometimes severe, and such patients should be treated with quinidine (q.v.). The average consumption of quinine sulphate in the world is 15,000,000 ounces a year, and the approximate average net cost of production is 18 cents per ounce. The importations into the United States in the fiscal year ended 30 June 1918 were 3,273,628 pounds of cinchona and other quinine-yielding barks, valued at \$810,775, and capable of supplying an average of 4 per cent (2,095,122 ounces) of quinine sulphate; and 1,445,702 ounces of quinia sulphate and other alkaloids and salts of cinchona bark, valued at \$656,945.

To manufacture quinine, the bark is ground to a No. 70 powder (screens of 70 meshes to the inch), and mixed with one-third its weight of slaked lime, made into a paste with water and dried thoroughly at 212° F. It is then powdered and mixed with petroleum and boiled about five hours, the alkaloids in the bark dissolving in the oil, or amyl alcohol may be used for the solvent. The powder is then allowed to settle, and the oil is drawn off and agitated with hydrochloric acid. The alkaloids in mixture, known commercially as quinoidine, now leave the oil and go to the acid-water, in which they are more soluble than in the oil. The oil and water separate upon standing, and the acid water is drawn off and neutralized with an excess of ammonia or soda, when the quinine and other alkaloids are precipitated together. The alkaloids are redissolved in very dilute sulphuric acid and then the solution is almost but not quite neutralized by very dilute soda solution cautiously added. It is then heated to the boiling point, and enough boiling water added to make 70 ounces of water for each ounce of mixed alkaloids. Upon cooling, crystals of quinine sulphate are thrown out, leaving the other alkaloids in the solution—called the mother-liquor (see QUINIDINE). The quinine is purified by recrystallizing several times from its solution in water at 212° .

History.—The virtues of the bark of what was afterward known as the cinchona-tree were discovered by the Jesuits in Peru about the year 1600. Prior to that date the Indians evidently knew that it had remedial powers, but they did not use it to any extent. In 1638 the Countess of Chinchon, whose husband, Don Luis Geronimo Fernandez de Cabrera Bobadilla y Mendoza, was viceroy of Peru, was cured of an intermittent fever by the use of this bark administered by her physician, Don Juan de Vega, on re-

quest of Don Francisco Lopez de Cañizares, corregidor of Loxa. Upon her return to Spain in 1640 the countess carried a supply of the bark with her, and through her it became known to the world. It was very fitting that 100 years later Linnæus should name the genus of trees bearing this bark for the countess—*Cinchona* (Linnæus erred in spelling; it should have been *Chinchona*).

The actual discovery and isolation of quinine is to be ascribed to the French chemists Pelletier and Caventon in 1820, although Gomez, a Portuguese, succeeded in isolating the febrifuge principle, which was practically quinine, in 1816. Sulphate of quinine was first made in America in 1823, and the house of Powers and Weightman, which was founded five years before this date, was undoubtedly the first to manufacture it for sale. Until about 1850 the only source of supply was found in the trees growing wild on the eastern slopes of the Andes from Colombia southward to Bolivia, and as quinine had become so valuable a remedy the world over, the native forests near enough to shipping ports to be economically available were almost exhausted so great had become the demand, for cinchona bark. The price had reached about \$20 per ounce. The Dutch, knowing that they had in Java the soil, climate, altitude and temperature almost identical with those in the Peruvian Andes, determined to secure trees or seeds and try to cultivate it there. (*Cinchona* requires an altitude of 5,000 to 7,000 feet, tropical temperature, without much variation, from 100 to 200 inches of rain a year, and a volcanic soil). The British government made the same attempt in India, but with poor results, because the same conditions of soil and rain do not prevail; and after about 50 years' endeavoring to raise cinchona in India and Ceylon, there only remain a few gardens owned by the government, the product of which is consumed in the army and among the natives, to whom it is sold through the post office at cost. The variety *Cinchona succirubra*, yielding cinchonidine, succeeds well in India.

The Dutch experiment, however, proved to be very successful and remunerative, although it involved almost insurmountable obstacles, loss of years of time and lives of earnest working scientists. The trees now thrive better even than their Peruvian ancestors, for the congenial environment found in Java, together with the methods of cultivation discovered by the Dutch, the most faithful of whom has been Van Leersum, government director of Cinchona undertakings, gave yields of as high as 10 per cent quinine sulphate, while an average of 2 to 5 per cent was a fair yield of the Peruvian trees. The annual average export of the Java plantations is 16,500,000 pounds of bark.

There are now thriving plantations in Bolivia and Colombia and Ecuador as well as in Peru, and with the modern methods of stripping the bark have met successfully the competition of the Java product. Consult McGilchrist, A. C., 'Quinine and Its Salts' (Calcutta 1911); United States Public Health Service Report No. 175, 'Quinine Prophylaxis for Malaria' (Washington 1914).

QUINISEXT COUNCIL, or **COUNCIL IN TRULLO**, council of bishops held (692) in the hall named Trullus of the imperial palace

at Constantinople. The design of this council was to supplement the purely doctrinal canons of the fifth general council (553) and of the sixth (660) with canons regulating discipline; for this reason it has been called in Latin, *Concilium Quinisextum* (Latin, *quintus*, fifth, and *sextus*, sixth), and in Greek *Synodos Penthektē* (Greek, *pente*, five; *hektos*, sixth). It was attended by 211 bishops, all Oriental, and its decrees have ever been repudiated by the Western Church. Among the rules of discipline enacted by this council is one declaring married men eligible to the orders of subdeacon, deacon and priest, but forbidding the marriage of one who is already in priest's orders.

QUINNAT SALMON. See SALMON.

QUINNIPIAC ("long water land"), an Indian tribe of the Algonquin linguistic stock, and probably forming a part of the Wappinger group, formerly residing on Quinnipiac River, New Haven County, Conn. Their principal village was on, or near, the present New Haven. In 1638 they numbered about 165; in 1735 they had increased to 250; in 1768 some of them moved to Farmington, where land was bought for them; in 1774 the original settlements were reduced to 38 natives.

QUINOA, *ké-nō-a*, an annual herb (*Chenopodium quinoa*) of the order *Chenopodiaceae*. It is a native of the Chilean and Peruvian Andes and extends intermittently to Mexico. It grows about three feet tall, bears triangular leaves, very inconspicuous greenish flowers and large seeds. In general the plant resembles the common lamb's quarters or goosefoot (*C. album*), a well-known weed in American gardens. In South America and to some extent in Europe the plant is cultivated for its seeds, which are nutritious and are made into meal or fed to poultry. Its young tender foliage is also used like spinach, a related plant. Since it is a favorite food of certain insects it has not been profitably cultivated in California, where it was tried.

QUINOLINE, CHINOLIN, LEUCOLINE, C_8H_7N . Runge (1834) isolated at a high boiling point an oily basic substance from coal tar to which he gave the name "leukol." Gerhardt (1842) obtained an oil by distilling quinine or cinchonine with caustic potash. He called it quinolein from its relation to quinine, but later the name was changed by Wöhler to quinoline. Hofmann (1843) showed that leukol and quinoline were identical. It occurs also in bone-oil and the tar from brown coal, strychnine and other plant alkaloids give it with caustic potash. As usually made in quantity by the interaction of 60 parts glycerine, 50 parts sulphuric acid and 19 parts aniline, which mixture, after heating, is added slowly to 12 parts of nitro-benzene and the whole boiled for about two hours, or until the reaction is complete. The nitro-benzene remaining unchanged is removed by blowing a current of air through the mixture, and this is made alkaline by adding caustic soda. It is then distilled with steam which carries over crude quinoline with some admixture of aniline. The latter is removed by fractionation and the quinoline is further purified by oxidation with the dichromates. Quinoline, when pure, is an oily liquid, with a specific gravity of 1.095 and a boiling point of 460° F.; at first colorless, but becoming dark on exposure to the air; possesses a penetrating, dis-

agreeable odor; is slightly soluble in water and has strong antiseptic properties. It absorbs moisture from the air readily, forming the hydrate. It is a basic substance, forming soluble and easily crystallizable salts with acids. It is used to some extent in medicine and the arts as an antiseptic, its action being to prevent putrefactive fermentation but not to interfere with alcoholic fermentation. It is used as a throat wash in diphtheria, but has not displaced iodoform in surgical dressings. It gives rise to many compounds used in the manufacture of dyestuffs.

QUINONE, in chemistry, a class name which is applied to organic substances derived from aromatic compounds by the replacement of two "ring" hydrogen atoms by two oxygen atoms. All the compounds of this class are colored and give colorless hydroquinones when reduced. Most of the quinones have the oxygen atoms in the "para" relations to each other. A few "ortho" quinones are, however, known. The simplest and first known of this class is ordinary quinone or benzoquinone, $C_6H_4O_2$; obtained by oxidation of quinic acid, but now usually prepared by electrolytic oxidation of aniline with a mixture of dilute sulphuric acid and potassium bichromate. Its long golden yellow prismatic crystals possess a peculiar pungent odor, and stain the skin yellow. Soluble in hot water or alcohol, they are volatile with steam and turn dark on exposure to the air, from which they absorb oxygen. On reduction it gives hydroquinone, $C_6H_4(OH)_2$, a soluble colorless crystalline body that is used extensively as a photographic developer. Quinone is a very active chemical substance, forming a large number of derivatives of economic interest chiefly in the manufacture of dyestuffs. Another very valuable member of this class is anthraquinone, $C_{14}H_8O_2$, a yellow crystalline body obtained by oxidation of anthracene. Related to it and obtained from it is the very valuable dye alizarin, the substance to which madder owes its value as a dyestuff. See ALIZARIN; HYDROQUINONE.

QUINONE-IMIDE DYESTUFFS. See COAL-TAR COLORS.

QUINQUAGESIMA, *kwîn-kwa-jés'i-ma*, **SEXAGESIMA**, **SEPTUAGESIMA**, the first, second and third Sundays before Lent. The words mean, respectively, 50th, 60th and 70th, and in the Roman calendar the names of the three Sundays are *Dominica Quinquagesimæ*, *D. Sexagesimæ* and *D. Septuagesimæ*, respectively. The use of the words is ancient, dating at least from the 7th century, but their meaning is obscure. Alcuin (9th century) suggested the numeration of 70 days from *Dominica Septuagesimæ* down to *Pascha Clausum*, the octave of Easter; but that leaves the other two names unexplained. Another explanation offered by Alcuin was that these two names are formed on the analogy of *Quadragesima* (Lent), being one and two weeks before the first Sunday in Lent; a false analogy, which assumes seven to be equal to 10; but false as it is, it led to calling the second week of Lent *Tricesima* (30th) and the third *Vicesima* (20th).

QUINQUARTICULAR CONTROVERSY. See ARMINIANISM.

QUINSY, an acute inflammation of the tonsils; acute parenchymatous tonsillitis. It is attended by fever, pain, headache, difficulty in swallowing (dysphagia), and frequently by suppuration. One attack seems to predispose to another. It is not uncommon for individuals to have attacks year after year at about the same time of the year. Disturbances of the digestive organs—diarrhœa, constipation, loss of appetite, nausea, vomiting, etc., are predisposing causes. Sudden changes of weather, exposure to damp and cold, especially after coming out of a heated room, are exciting causes.

Quinsy sets in with an uncomfortable feeling in the throat, and fever sometimes high, preceded at times by chilliness. The patient is restless and irritable, the tongue becomes covered with a thick yellowish coating, the breath is unpleasant, saliva drools from the mouth, there is difficulty in opening the mouth, swallowing is attended with great effort and pain and sometimes food returns through the nose. Pain may be severe most of the time, shooting toward the ear upon the affected side. Swelling externally behind the ears and involving the glands of the neck may be marked. A thick tone of the voice, thirst, headache, snoring and dryness of the throat are common symptoms. Sometimes breathing is impeded, especially if both tonsils are involved. On examination of the throat one or both tonsils are seen to be bright red and sometimes covered with patches of yellow secretion. The soft palate is red, greatly swollen and oedematous, as is also the uvula, which not infrequently adheres to the tonsil. Quinsy may terminate either in resolution or suppuration. If resolution is to take place, in about four or five days the inflammation begins to subside, and the patient in from 10 days to a fortnight may resume his ordinary employments. If suppuration is to occur, the tonsillar swelling becomes greater, and if both tonsils are inflamed they may meet, causing great discomfort. When pain and discomfort become almost unbearable, an inflamed tonsil generally breaks and great relief and speedy convalescence follow.

Occasionally, if the disease is taken at the outset, it can be absorbed by a saline purgative or an emetic and the use of one or two drops of tincture of aconite every hour. If it continues in spite of early treatment, it will probably run its course, though much can be done to palliate. Keep the patient quiet (sometimes in bed), and give hot or cold liquid foods, whichever he can swallow best. Washing out throat with hot water every hour may be comforting, as also may inhalations of the steam of hot water, cooled by passing through a towel or a long tube. Saline laxatives are useful; so are hot compresses about the neck. Ice and cool drinks have an efficacious value. Local applications and the use of medicines and stimulants should be left to the judgment of the physician. Abscesses should be opened (not left to mature) and astringent gargles afterward used. Diseased tonsils should be excised.

QUINTAIN, an apparatus used in a military sport or exercise by men on horseback, formerly practised in England to try the agility of the country youth. The quintain was an up-

right post with a cross-bar on the top of it, turning round on a pivot. To one end of the bar was suspended a bag of sand, the other end was broad and flat. The horseman had to ride tilt at the flat end with his lance and endeavor to strike it and pass on before the bag of sand could whirl round and strike him on the back.

QUINTAL, a weight of 100 or 112 pounds, according to the scale used. See WEIGHTS AND MEASURES.

QUINTANA, kên-tā'nā, Manuel José, Spanish poet: b. Madrid, Spain, 11 April 1772; d. there, 11 March 1857. He was educated in the University of Salamanca, studied law, engaged in practice at Madrid, where he occupied several government offices, and soon turned his attention to literature. He was author of almost all the manifestos and proclamations issued in the War of Independence and his patriotic poems soon won for him great popularity. He edited the journal *Variedades de Ciencias, Literatura, y Artes*, founded the *Semanario Patriótico* and urged upon the people the necessity of resisting Napoleon. After the restoration he was imprisoned in 1814-20, and then was released by the revolution. He lived in retirement from 1823 until 1833 when he was appointed preceptor to the infant queen, Isabella, and president of public instruction. In 1835 he was elected senator and was afterward highly esteemed at court. He was one of the leading poets of his time, attaining a European reputation. As a historian he is well known by his 'Vidas de los Españoles célebres' (1807-34). His complete works are published in Rivadevieyra's 'Biblioteca de autores españoles' (Vol. XIX, 1852), and by Rojas (1897-98).

QUINTET, a musical composition for five instruments or voices, accompanied or unaccompanied. (1) Quintets for stringed instruments have been written much less frequently than quartets, by reason of their complexity. Boccherini, nevertheless, wrote 125. Among famous string quintets are Beethoven's two in C and E flat, Mendelssohn's in B-flat and Schubert's in C. There are various quintet combinations, including brass and wood-wind, as Mozart's in E-flat for oboe, clarinet, horn, bassoon and piano. (2) Vocal quintets are also rare, but very effective. The most notable modern example occurs in Wagner's opera of 'Die Meistersinger.'

QUINTILIANUS, kwin-tīl-i-ā'nūs, Marcus Fabius, Roman rhetorician: b. Calagurris (Calahorra), Spain, about 40 A.D.; d. about 118. He was educated at Rome, where he studied under Domitius Afer, and about 69 began to practise as an advocate. Subsequently he became a teacher of rhetoric, and had Pliny the Younger and the two grandnephews of Domitian as pupils. Domitian bestowed on him the consular rank, and under the endowment of Vespasian he was the first public instructor to be paid from the imperial treasury. His first important treatise, 'De Causis Corruptæ Eloquentiæ,' is no longer extant. His great work, 'De Institutione Oratoria' (12 vols.), was written about 93, and embraces a statement of his theory of education together with a discussion of the principles, scope and matter of oratory; also its manner under the general term style. (See INSTITUTES OF ORATORY). The

best editions of Quintilian are those of Burmann (Leyden 1720), Capperonier (Paris 1725), Gesner (Göttingen 1738), Spalding and Zumpt (Leipzig 1798-1829) and Halm (1868-69). There are also special editions of the 10th book, among which are those of Bonnell (1851), Kruger (3d ed., 1888), Peterson (1891); this book criticizes Greek and Latin literature, from the point of view of the orator, and its usefulness in forming a vocabulary. The work as a whole is remarkable for its perspicuity and well-balanced judgment, as well as for the beauty of its graceful diction. From the 15th century, when the manuscript was first discovered, Quintilian was considered the standard authority on classical education throughout the Renaissance period in Europe. The effect of his system is still recognizable in the curricula of classical schools. Consult Schanz, M., 'Geschichte der römischen Literatur' (Munich 1913); Woodward, T. H., 'Education During the Age of the Renaissance' (Cambridge 1906).

QUINTILIUS, kwin-tīl'i-ūs, **Aurelius Claudius**, Roman emperor, 270 A.D. He was a brother of Claudius II and at the latter's death was elevated to the throne, but as the army of Sirmium had elected Aurelian emperor, Quintilius, seeing himself deserted by his followers, committed suicide. He seems to have been a man of unblemished character and to have possessed the high attributes of his brother. The length of his reign is usually placed at 17 days, but the large number of his coins extant indicates that he held the office for some months.

QUINTUPLE ALLIANCE. See **QUADRUPLE ALLIANCE**.

QUINTUS CALABER, or **SMYRNAEUS**, Greek poet: belonging probably to the end of the 4th century A.D. His surnames are derived from the discovery of his poem in Calabria (in a convent at Otranto), and his mention of Smyrna as the place of his residence. His poem, *Παραλειψόμενα Ομήρω* ('Supplement to Homer'), is a continuation of the 'Iliad,' in which he imitates, with very little originality, the poets of the epic cycles. A critical edition of this, by Tychsen, with remarks by Heyne (1807), was published by the Bipont Society. There is also an edition by Köchly (1853), and Zimmerman (1891). Consult Paschal, G. W., 'A Study of Quintus Smyrnaeus' (Chicago 1904); also Christ-Schmid, 'Geschichte der griechischen Literatur' (Vol. II, Pt. 2, Munich 1913).

QUINZE JOYES DE MARIAGE, kânz' jwâ dē mā-ri-āj, **Les** (the 15 joys of marriage), a famous French satire usually credited to Antoine de La Sale and written between 1448 and 1456. The title was borrowed from a popular litany, 'Les Quinze Joies de Notre Dame,' its profanity being in keeping with the lack of humane or moral sentiments in the satire. However, its wit and masterly style are unquestionable. A chapter is devoted to each of the 15 "joys" which are made to designate the miseries of husbands. Consult Jannet, P., 'Les Quinze Joyes de Mariage' (1857); Henckenkamp's edition (Halle 1901).

QUIRINAL, one of the hills of Rome, not included in the ancient Septimontium, or "City of the Seven Hills," but part of the four re-

gions of the city, and included in the Servian Wall. Next to the Palatine and Capitoline, it is the oldest and most famous part of the city. The temples of Flora, Salus and Quirinus were on the Quirinal and also the baths or the great *thermae* of Diocletian and Constantine. Pope Gregory XIII began here the erection of a summer residence which was completed by Paul V. Victor Emmanuel took possession of it in 1870, and it has since been the residence of the king of Italy. One of the principal treasures of the palace is the ceiling decoration of one room,—painted by Overbeck. The subject is 'The Flight of Pius IX in 1848.' Other treasures are an 'Annunciation' by Guido Reni, and several other works of art. (See **ROME**). Consult Baedeker, K., 'Central Italy and Rome' (15th Eng. ed., Leipzig 1909) and Platner, S. B., 'The Topography and Monuments of Ancient Rome' (2d ed., Boston 1911).

QUIRINUS, kwī-rī'nūs, Roman deity, ranking next to Jove and Mars. His origin appears indistinct, but he is represented as a war god prepared for battle in times of peace. The third great flamen was assigned to his worship and his temple stood on the Quirinal Hill near the Porta Quirinalis. He was honored by the Colline Salii and a new building was erected in his honor 293 B.C., which after its destruction by fire was replaced with an imposing structure by Augustus 16 B.C. In the 1st century B.C., however, the belief that Quirinus was Romulus raised to the rank of a divinity gained credence and this opinion was favored by Cæsar and Augustus. His annual festival was celebrated on 17 January, the date of the supposed translation of Romulus to heaven. Consult Fowler, W. W., 'Roman Festivals' (London 1899) and Wissowa, Georg, 'Religion und Kultus der Römer' (Munich 1912).

QUIRINUS, Publius Sulpicius (Gk. form **CYRENIUS**), named in Luke ii as governor of Syria. According to Tacitus he was elected consul in 12 B.C.; accompanied Gaius Cæsar as tutor in the East in 2 A.D.; and was appointed to make a census of the newly annexed district of Judæa, an innovation in that country. The difficulty in reconciling the date of this census with the historical facts concerning the birth of Christ has excited considerable controversy. Consult Cheyne and Black, 'Encyclopedia Biblica' (London and New York 1903).

QUIRITES, kwī-rī'tēz, originally the inhabitants of Cures, a Sabine town, and a name afterward applied to that portion of the Sabines who at an early period dwelt in Rome. "Quirites" being applied to them in their civil capacity, while "Romani" was applied to them in their political and military capacity. On this account it was regarded by the soldiers as a great indignity to be addressed as "Quirites," and Julius Cæsar on one occasion quelled a rising mutiny among his troops merely by scornfully haranguing them under the appellation of "Quirites." But the contumelious sense of this name had banished before the time of the Augustan Age.

QUIROGA, kē-rō'gā, **Juan Facundo**, Argentine politician and soldier: b. Rioja, Argentina, 1790; d. in the barranca of Yaco near Cordova, Argentina, 1835. He was educated in Spain and, on his return to Argentina, he be-

came a soldier in the army of General Ocampo (1810). Later he joined the Army of the Andes, from which he deserted because he did not find conditions to his liking. He seems to have led a wild life and to have been so addicted to gambling that he frequently found himself penniless. Finally he was arrested in 1818 on a charge of treason and imprisoned with a common herd of Indians and half-breeds in the fortress of San Luis. There is organized the prisoners, among whom were a number of officers and soldiers, broke out of the prison and led them to the mountains where he was received as a hero by the natives of the interior. He organized a band of rude soldiery which made him practically the ruler of northeastern Argentina in 1820. In 1827 he appointed a governor of La Rioja, secured the election of Dorrego as President and, though defeated by General Paz in 1830, became governor of Buenos Aires in 1834. He was assassinated in the following year. He was a man of very strong will power and his ascendancy over his followers was perhaps greater than that of any other leader of his country at that time.

QUIROGA, Vasco de, Spanish-Mexican prelate: b. Madrigal de Castilla la Vieja, about 1470; d. Uruapam, Mexico, 14 March 1565. He was graduated in law from the University of Valladolid, and owing to his brilliant scholastic record, his success in his profession and his influence at court, he was appointed oidor of the audiencia of Mexico. He arrived in the capital of New Spain in 1531, 10 years after the fall of the empire of the Aztecs and while the conquest of a considerable part of modern Mexico still remained to be effected. Quiroga, in a very troublesome age, surrounded by the turbulent soldiers of the Conquest and the unscrupulous adventurers who accompanied or followed them, performed his part in the government of New Spain with justice and firmness and gained the respect of Spaniard and native alike. After six years' residence in Mexico, during which he had gained a vast experience of the country, he was appointed bishop of Michoacan, the ancient kingdom of the Tarascans, with official residence at Pátzcuaro (1537). There he interested himself in the welfare of the Indians, founded the College of San Nicolás and a girls' school; translated doctrinal works into the native tongue and has left a volume of sermons and numerous other works of great interest to the student of this early period in the history of Spain in America. At the age of 95 Quiroga was still actively at work, when he took sick and suddenly died while on one of his pastoral visits.

QUIT and GOAL, in *astronomy*, two terms introduced by Prof. H. A. Newton of Yale University to define the two points opposite each other in the heavens toward one of which the earth is at the time moving in its orbit round the sun and from the other receding.

QUIT-CLAIM, in *law*, a deed of release; an instrument by which some claim, right or title, real or supposed, to an estate, is relinquished to another without any covenant or warranty, express or implied. See **DEED**.

QUITCH. See **COUCH GRASS**.

QUITMAN, kwit'man, John Anthony, American statesman and soldier: b. Rhinebeck, N. Y., 1 Sept. 1799; d. Natchez, Miss., 17 July 1858. He studied law and in 1821 removed to Natchez, Miss., where he established a successful law practice. He was elected to the legislature in 1827; was chancellor of the Superior Court of Mississippi in 1828-31 and 1832-34. He was president of the State senate in 1835; in 1836 served as ex officio governor of the State and in 1839 was judge of the High Court of Error and Appeals. Interested in the cause of Texan independence he labored earnestly in its behalf. At the outbreak of the Mexican War he was made brigadier-general of volunteers. He distinguished himself in various battles of the Mexican campaign; was promoted major-general of volunteers and received from Congress a sword and a vote of thanks. He was appointed governor of the City of Mexico by General Scott and on his return was elected governor of Mississippi in 1850, which office he resigned the following year when accused of complicity in the Lopez-Cuban expedition, a charge of which he was acquitted. In 1855-58 he served in Congress, where he was an ardent supporter of States rights. Consult Claiborne, 'Life and Correspondence of John A. Quitman' (1860).

QUITMAN, Ga., city and county-seat of Brooks County, 50 miles northeast of Tallahassee, Fla., near the southern border of the State, on the Atlantic Coast Line and the South Georgia and West Coast railroads. It is situated in an agricultural district and produces large quantities of hams and bacon, as well as stock and cotton. There is also a lumber industry. Pop. 3,915.

QUITO, ké'tò, capital of the republic of Ecuador, situated only a few miles south of the equator, but at a height of more than 9,000 feet above sea-level. Climatic results of proximity to the equatorial line are modified and nearly equalized throughout the year by those of altitude; the temperature is, therefore, spring-like. It is, however, an inaccessible inland place; until 1903 (see **ECUADOR**) neither railway nor highway connected it with the seacoast. A part, at least, of the journey to Guayaquil, 165 miles away, was usually made on mule-back, along a mere bridlepath which crossed the breast of Mount Chimborazo at a height of 14,000 feet; and the rare action of the atmosphere at that altitude can seldom be supported without discomfort. For the transportation of freight from the port to the interior two or three weeks have hitherto been required. Owing to its remoteness and the lack of highways, the city is visited by few strangers, and has no good hotels, no carriages or wagons. Yet the streets are lighted by electricity, and the list of public institutions devoted to education, the Roman Catholic Church and the government is quite impressive, including an astronomical observatory, botanical garden, school of agriculture, and other adjuncts of a "central university," with faculties of *belles-lettres*, science, law and medicine. The architecture in general is that of a country subject to earthquakes—low and substantial. Features deserving special mention are the beautiful park called the Alameda, and the Sucre Theatre. The estimate of population (probably much too liberal) in semi-official

publications is 70,000. It was originally the central town of an ancient Indian nation. In 1470 it was captured by the Incas, who in turn surrendered it to the Spaniards in 1534. During the Spanish rule, it was the capital of the presidency of Quito. Frequent earthquakes have demolished the town, the last having occurred in 1887. See also *ECUADOR, History*.

QUIVIRA, *kē-vē-rā*, a "province," reputed to have been populous and rich in gold and other things, of which Francisco Vasquez Coronado, the Spanish explorer, received news from a plains Indian, known as the "Turk," while in winter quarters on the Rio Grande in New Mexico in 1540-41. Coronado started from Pecos pueblo in New Mexico, with his army, guided by the "Turk," in the spring of 1541, and after long wandering over the buffalo plains of Texas sent the larger part of his force back to New Mexico and continued his journey due northward for 35 or 40 days, encountering the first settlement of Quivira about the present Great Bend, Kan. The province was found to consist merely of a group of villages, composed of grass lodges and inhabited by a tribe, recently identified as the Wichitas, which raised corn and hunted the buffalo. Coronado put the "Turk" to death, and after exploring the country for several months returned by a more direct route to New Mexico. Coronado's disappointment having become forgotten, the name Quivira lingered in the minds of later Spanish explorers of the southwest and grew to be the watchword of an unexplored Eldorado. After the abandonment of the Indian pueblo of Tabirá, in eastern New Mexico, about 1675, the idea of Quivira and its supposed wealth was transferred to the ruins of the New Mexico village, and the name "Gran Quivira," then applied to it, has since been popularly retained. Consult Hodge, 'Coronado's March to Quivira,' in 'Brower's Memoirs of Explorations in the Basin of the Mississippi' (1899).

QUIXOTE, *Don*. See **DON QUIXOTE**; **CERVANTES**.

QUO VADIS. Sienkiewicz, early in the nineties of the last century, devoted himself to a study of the Latin writers of the first few Christian centuries and the result of these studies was 'Quo Vadis,' a historical novel of the time of Nero, which appeared in 1895 and immediately created a sensation throughout the world. By 1900 nearly 2,000,000 copies of the English translation, made in 1896 by Jeremiah Curtin, were sold, and in France, Italy and America there appeared dramatizations of the story. The author's realistic treatment of the early Christians provoked heated discussions in the Catholic Church of Poland and an attempt was made to prohibit the reading of the novel, but elsewhere it was received with undivided enthusiasm. In Genoa it was, in 1899, made the subject of a social study by Semeria, 'L'arte e l'apologia cristiana,' in connection with the Superior School of Religion. In spite of some historic crudities, he proclaimed it a chef d'œuvre of Christian art. The chief merit of the story consists in the ever-present contrasts between voluptuous and cruel Rome on the one hand and the meek spirit of the dwellers in the Catacombs on the other, which makes the char-

acters appear in far greater relief than in Cardinal Wiseman's 'Fabiola' or in similar stories by Cardinal Newman and Canon Farrar. Thus Petronius, the Stoic and Sybarite, representing the over-refinement of antiquity and his Greek slave, Eunice, who passionately clings to him unto death, are contrasted with the pagan, Vinicius, and his Christian bride, Lygia; the royal performer in the circus is opposed to the fisherman who shall rule over the world; the trickster, Chilon, is brought in contrast with the meek "forgiving Christian, Glaucus." Over all of them, representing the struggle of two worlds, stand Nero and Saint Peter, the first laboriously limned in his moral degradation, thirsting for new impressions, no matter at what cost of human lives, the other, expressing himself in the fewest of words, which bear witness to the coming victory of the new Church over the ancient world. Among the numerous criticisms of 'Quo Vadis,' the most elaborate is that by Tarnowski, in his 'Studia do historyi literatury polskiej' (1897, Vol. V, pp. 268-344).

LEO WIENER.

QUO WARRANTO, *in law*, a writ issued by a court to a person commanding him to show "by what warrant" he holds an office, franchise or the like. The writ originated at an early date in England, where it has been much modified by statute and is now called an information in the nature of a quo warranto. Though nominally a criminal writ, it has for a long time been considered a civil writ and has in recent years been judicially declared in England to be such. It may be brought in England, on leave of court, by a private person.

In most jurisdictions in the United States it is brought by the attorney-general of the State either officially or in the name of a private person. In some States, as New York, statutory actions in the nature of a quo warranto have been substituted for it. Quo warranto proceedings may be instituted against municipal corporations, but in practice it is seldom done. It has been held that this writ may be used against militia officers, sheriffs, school trustees, lieutenant-governors, mayors and other municipal officers, but not against policemen. Another important use of quo warranto is to determine whether there has been a non-user or misuser of a franchise of a corporation.

QUODLIBET, (1) a form of scholastic argument in use in the 13th and 14th centuries which might be founded on any subject, but was usually theological. The discussion was of an elaborate and subtle form and about a dozen books of quodlibets written between 1250 and 1350 are in existence. (2) *In music* the term designates a fanciful or humorous combination of well-known melodies, sometime known as a "Dutch concert" and popular in German student gatherings. The diversion consists of the singing of familiar melodies an upon coming to a word which forms the first word of another song transferring without pause to its words and music until another word gives occasion for another change.

QUOIN, *koin* (French, *coin*; Latin, *cuneus*, a wedge), a technical word for a wedge; in artillery, the wedge used to elevate and d

press a cannon or other piece of ordnance; (2) *in printing*, the wedge used to fix pages of type within the chase; (3) *in architecture*, the term is applied to any external angle, but especially to the angular courses of stone projecting beyond the plane surface of the wall at the corner of a building and specifically designated rustic quoins.

QUOITS, kwoits, a game somewhat resembling the throwing of the discus among the ancients; only the discus was flat, while the quoit is ring-shaped. (See *Discus*). The quoits are made of metal, usually iron, and are comparatively thick at the inner edge of the ring, but sharp enough at the outer edge to stick in soft clay when properly thrown. In size they vary from eight to nine and one-quarter inches. The game is played on a ground from 18 to 24 yards in length, at each end of which a pin called a hob is fixed in the ground to serve for a mark. The object of the game is to throw the quoits from one end of the ground to the other so as to make them stick in the ground as near the hob as possible. The best shot, called a ringer, is when the quoit surrounds the hob. The players are divided into sides and each player has two quoits, which he delivers in succession. The winning side counts one for each quoit that it has nearer the hob than the nearest of the losing side and if it has a ringer it counts two for it. The rules as to the size of the quoit, the distance between the hobs and other particulars vary with different players. In the United States the game is often played with cast-off horseshoes. The game is popular in England, Scotland and Canada, and in the two latter countries is the summer sport of the curling clubs. In the United States, under the auspices of the Grand National Curling Club of America, there is an annual contest for the Bell quoit medal, given by David Bell of Buffalo, N. Y., in 1868. Consult Spalding's Athletic Library, 'How to Pitch Quoits' (No. 167; New York, published annually).

The game is popular in England, Scotland and Canada, and in the two latter countries is the summer sport of the curling clubs. Consult Spalding's Athletic Library, 'How to Pitch Quoits' (No. 167; New York, published annually).

QUORATEAN (kwō-rā-tē'an) INDIANS, an American linguistic stock, comprising the Kworatem tribes, from which the stock derives its name. The name was proposed by Gibbs and adopted by Powell. The tribes occupy Lower Klamath River from the mountains a little above Happy Camp to the junction of the Trinity and Salmon River from its mouth to its sources, in northwestern California. See *KAROK*.

QUORUM, in old English law, a collective name for those justices of the peace whose presence is necessary to constitute a bench. Also such a number of officers or members of a body as is competent by law or constitution to transact business.

QVIGSTAD, kvig'stad, Just Knud, Norwegian educator and philologist: b. Lyngen, 1853. He was graduated at the University of Christiania and was rector of Tromsø Seminary for Teachers 1883-1909. He published several works on the ethnography and languages of the Finno-Ugrian and Lappish races, which are international standards. He was minister of public instruction under the premiership of W. Konow from 1909 until 1912, when he resigned to return to his rectorship at Tromsø.

QVISTGAARD, kvist'gård, J. W. von Rehling; Danish miniature painter: b. Orsholtsgaard, parish of Tikjob, 1877. He was graduated at the Royal Agricultural College of Copenhagen and in opposition to family prejudice, as a member of the Danish nobility, selected art as a profession. After a brief course of study in Copenhagen under Johan Rohde, he came in 1901 to the United States, where, although practically self-taught, his original and superior work soon attracted attention. In 1906 he visited London and Paris, and in 1909 by royal command returned to Copenhagen to make miniatures of the king and queen and other members of the royal family. He returned to New York in 1912 where he has since resided. Special exhibitions of his works were held at Ghent in 1913 and New York in 1914, and have been prominent in the principal miniature exhibitions of Europe and America. Notable productions include an oil portrait of Theodore Roosevelt, and miniatures of Mrs. Paul Reinhardt, Mr. and Mrs. Charles M. Pratt, and Dr. George C. Williamson, the well-known expert on miniatures.

R

R the 18th letter of the English and other alphabets derived from the alphabet of the Latins. The corresponding letter of the Greek alphabet, rho, has the form Ρ, ρ, which is the ρ of the ancient Phœnician alphabet, with the loop turned to the right; in some very ancient Greek Italic inscriptions occurs the form R which was adopted by the Romans. R is classed as a liquid or semi-vowel with *l*, *m* and *n*. Its normal sound is doubtless either the *trill* produced by vibration of the tip of the tongue raised toward the front palate or the *burr*, which is produced by a vibration of the lower part of the tongue and the uvula; the trill is heard in the speech of the Latin nations — Italians, French and Spanish; the burr in that of the Germans and Scandinavians. In present English speech the *r* is sounded with a very faint trill or quite without a trill, save in the pronunciation of the people of certain counties of England, who produce it with a guttural vibration; in the pronunciation of this letter by the Scotch and Irish the trill is distinctly heard. When *r* begins a syllable and when it follows a consonant — as in *race*, *trap*, it is distinctly a consonant; but in other situations, as in *nerve*, *hard*, *never*, it is really a vowel sound. This vowel sound is related to the vocalic *r* of Sanskrit and the Slavic languages. In the faulty or affected pronunciation of certain classes *r* becomes equivalent to *w*, for example, *very* for *very*. The two liquids or semi-vowels, *r* and *l*, are sounded when the voice is modified by certain positions of the tip of the tongue relatively to the front palate; hence the two letters are freely interchanged between one language and another and within the vocabulary of one language; Spanish *azul* is English *azure*; from *parabola* comes, indirectly, *palaver*. There are races or peoples who are unable to pronounce the *r* with either the trill or the burr or even with the slight vibration heard in English speech; in such case *l* takes the place of *r*. Besides the dental or trill *r* and the vocalic *r*, the Sanskrit languages and certain others have a cerebral *r* formed by the tongue-tip against the hard palate. When in Greek a word or syllable begins with *r* that *r* is always aspirated, as is the second *r* when *r* is doubled, and the ancient Romans represented this aspiration by inserting *h* after the *r*; this *h* we retain, though we recognize no difference between the *rh* of *rhabdomancy* and the simple *r* of *rabid*. In many English words the *r* found in their Anglo-Saxon originals is dropped; for example, *spræcan* becomes *speak*; on the other hand, we insert *r* in words which in their ancient form were without it; for example, Anglo-Saxon *brydguma* becomes

bridegroom; and French *cartouche* becomes *cartridge*. *R*, stands for "royal" in many abbreviations. *R* in pharmacy stands for *recipe* (take). See ALPHABET.

RA-MA'S BRIDGE. See ADAM'S BRIDGE.

RAAB, räb, Johann Leonhard, German etcher and engraver: b. Schwaningen, near Anspach, Bavaria, 29 March 1825; d. Munich, 2 April 1899. He was educated at Nuremberg and at the academy in Munich and received an appointment as professor of engraving at the latter place in 1869, which he held until 1895. His work includes engravings after Raphael, Titian, Veronese, Kaulbach, Lessing, Schwind, Ramberg and others, besides a collection of 50 etchings reproduced from the most notable works in the old Pinakothek at Munich. He was a member of various art academies and received gold medals at Paris, Berlin, Vienna and Munich.

RAAB (Győr, dyër), Hungary, capital of a province of the same name, situated at the confluence of the Raab with a minor branch of the Danube, the so-called Little Danube, 70 miles southeast of Vienna, a position uniquely advantageous from both a military and commercial viewpoint. Its importance dates from early Roman occupation when it was called Arabona or Rabona. The Turks held it 1594–98. In the 18th and early 19th century it was an important fortress. In 1809 the combined Austrian-Hungarian forces were defeated here by the French troops under Eugene Beauharnais. During the Hungarian revolution it was stormed by the Austrians on 28 June 1849. It is the centre of a number of railroad lines, seat of the provincial authorities and of a bishop, possesses high schools, normal schools and grammar schools, carries on an extensive trade in grain, horses and pigs, and has a number of industrial establishments for the manufacture of machinery, cutlery and oil. The population of the province is about 92,000, that of the city 44,300.

RAABE, rä'bë, Wilhelm, German novelist and poet: b. Eschershausen, duchy of Brunswick, 8 Sept. 1831; d. 15 Nov. 1910, in the city of Braunschweig. After attending the gymnasium in Holzminden and Wolfenbüttel, he entered a book store as apprentice in 1849. He used this opportunity for wide reading and enriched himself with the tales and folklore of his own and other countries. In 1855 he entered the University of Berlin to study the humanities. In the autumn of 1856 appeared his first book, 'Die Chronik der Sperlingsgasse', under the pseudonym Jakob Corvinus. The book, which contains sketches of life among

the German bourgeoisie, was very successful and Raabe became well known. Being thus encouraged he gave up his studies and devoted himself entirely to literary work. From 1862 to 1870 he lived in Stuttgart. Then he again returned to Braunschweig and remained active until the end of the century, publishing upwards of 30 novels and a number of short stories and sketches.

His life work may be divided into three periods. During the first he wrote with a light touch, producing a series of pictures of German life from the abundance of his imagination and experience, among which are 'Die Chronik der Sperlinggasse' (1856), 'Die Kinder von Finkenrode' (1859) and 'Unser Herrgotts Kanzlei' (1862). The influence of the pessimism of Schopenhauer is evident during the second period. Representative works of this period are 'Der Hungerpastor' (1864), 'Abu Telfan' (1867), and 'Der Schüd derump' (1870). These three works are sometimes referred to as a trilogy. While they are independent of each other in substance, they do represent a distinct epoch in the life of Raabe.

During the third period of the novelist's life his works no longer show this pessimistic strain. A genial humor pervades them, though they frequently deal with serious subjects. 'Horacker' (1876) perhaps best represents this tendency. 'Der Dräumling' (1872), and 'Deutscher Mondschein' (1873), also come under this head. Of his numerous later works 'Das Odfeld' (1889) and 'Die Akten des Vogel-sangs' (1895) seem to be most read.

Raabe has been continually gaining in the estimation of the German people. This was especially shown at the celebration of his 70th birthday in 1901. He is perhaps the most distinctly German of modern novelists and story writers. There is hardly a situation in the life of the average German that has not been portrayed by Raabe. His early works were influenced to some extent by Jean Paul. Later he also shows evidences of having read Dickens and Thackeray. In 1911 a selection of Raabe's poems was published. Consult Brandes, W., 'Wilhelm Raabe' (Wolfenbüttel and Berlin 1906); Gerber, Paul, 'Wilhelm Raabe, Eine Würdigung seiner Dichtungen' (Leipzig 1897); 'Gesammelte Erzählungen' (2d ed., Berlin 1901); Spiero, H., 'Wilhelm Raabe' (Bielefeld 1911).

WILLIAM F. HAUHART,
Assistant Professor of German, University of Michigan.

RAB AND HIS FRIENDS, a short story by Dr. John Brown (q.v.), an Edinburgh physician, published at Edinburgh in 1859. Rab's friends are his master and mistress, James Noble, the Howgate carrier, and his wife, Ailie. Perhaps no truer, more convincing dog character exists in literature than that of ugly, faithful Rab. The pathos in the simple lives of himself and his friends is heightened by the tinge of Scotch dialect, as well as by the author's wise self-restraint. It has gone through many editions both in England and in the United States.

RABANUS, ra-ba'nūs, or **HRABANUS**, Maurus, Carolingian prelate: b. Mayence, about 776; d. Winkel, near Mayence, 4 Feb. 856. His education was obtained in the cloister school

of Fulda, and later at Tour, where his instructor, Alcuin, surnamed him Maurus after the legendary founder of the order of Saint Benedict in France. He took the Benedictine vows at an early age, was ordained deacon in 801 and priest in 814. He became the head of the school at Fulda, which under his guidance became the most famous monastery school in Germany, and in 822 was elected abbot of the monastery. In 842 he resigned and retired to Petersberg, but came again into public life in 847, when he was elected archbishop of Mayence. He was one of the bitterest of the opponents of the monk Gottschalk, the originator of the predestination controversy in the 9th century. He was one of the most learned men of his time and greatly advanced the spiritual, intellectual, artistic and material interests of his see. His literary activity was considerable, resulting in commentaries on the Old Testament, on the Gospels of Saint Matthew and Saint John and the Pauline Epistles, devotional books, homilies, hymns, polemics and a Latin-German Glossary to the Bible. He also wrote 'De Universo' (22 vols.), a sort of encyclopedia. His 'Opera Omnia' are comprised in J. P. Migne's 'Patrologiæ Cursus Completus' (Vols. CVII-CXII, Paris 1851-52), reprinted from the uncritical edition of G. Colvenerius (Cologne 1626). This edition contains his life by the monk Rudolph, and by Johann Trithemius. His poems have been edited by E. Dümmler in 'Poetæ Latini Aevi Carolini' (Vol. II, Berlin 1884). His pedagogical writings have been edited in German by I. Freundgen (Paderborn 1889). A. Knopfler has edited his 'De Institutione Clericorum Libri Tres' (Munich 1901). Consult Hablitzel, J. B., 'Hrabanus Maurus' (Freiburg i. B. 1906); Koehler, 'Hrabanus Maurus und die Schule zu Fulda' (Chemnitz 1870); Kunstmann, F., 'Hrabanus Magnentius Maurus' (Mainz 1841); Richter, 'Hrabanus Maurus' (Malchin 1882); Schaff, P., 'History of the Christian Church' (Vol. IV, New York 1885); Spengler, T., 'Leben des Heiligen Rhabanus Maurus' (Regensburg 1856); Tuernau, D., 'Rhabanus Maurus, der Praeceptor Germaniae' (Munich 1900); West, A. F., 'Alcuin and the Rise of Christian Schools' (New York 1893).

RABASA, rā-bā'sa, Emilio, Mexican lawyer and party leader: b. 1856. He was educated at the University of Mexico, specializing in international law, and has written the best Mexican works on that subject. He was a leader of the Científico party in the later years of the Diaz administration, and was subsequently slated for Ambassador to the United States. He was ranking member of the Huerta delegation to the A. B. C. Mediation Conference at Niagara Falls, Ontario, in 1914. He is author of several novels under the pseudonym of SANCHO POLA, and of many political treatises, among them 'La organización política de Mexico' (1917).

RABÁT, rā-bāt (RIBÁT'), or **ARBÁT**, also known as NEW SALEH, Morocco, in the province of Fez, on the Atlantic Coast, at the mouth of the river Bu Regrag and on its southern bank, 62 miles west of Mequinez. It stands on a rocky plateau and is surrounded by massive reddish-brown fortifications. A conspicuous feature from the sea is the Hasan Tower, a

DOMESTIC RABBITS.

1. Wild Rabbit. 2. 3. French Rabbits. 4. French Lop-Ear. 5. Norman Rabbit. 6. Angora Rabbit.

minaret 180 feet high, a remnant of an ancient mosque. Rabát's manufactures are carpets, woolen, cotton and leather goods. The Sallee pirates formerly built their ship at Rabát. It is one of the capitals of Morocco, and the sultan has a palace there in which he resides part of the year. At present it is also the seat of the government and the residence of the French president-general. Although the value of its harbor is decreased by the presence of a dangerous bar, its imports in 1916 were the second largest of all Moroccan ports, amounting to \$6,290,000, while its exports in the same year totaled \$638,500. It has a post office, telephone, telegraph and wireless station. On the hills west of the town are the ruins of Sala, a Roman colony. Pop. about 37,548, of whom 9,748 were Europeans.

RABBA, rā'bā, British West Africa, province of Nupe in northern Nigeria, on the left bank of the Niger, about 200 miles above the confluence of the Niger and Benue. In the early part of the 19th century it was a town of considerable importance, having some 40,000 inhabitants and carrying on an extensive trade in slaves and ivory. By 1867 the African explorer Rohlfs reported that only some 500 people were living there. Since the establishment of British rule it has recovered its former position to some extent.

RABBI, a title of honor among the Hebrews; "my teacher," "master." John expressly states that the word was equivalent to "teacher" (Greek *didaskalos*, rendered in the Authorized Version "master"; John i, 38). There is another form of title *rabboni*, found in the New Testament. The form *rabban*, the Chaldaic form of the Hebrew "rab," was considered the most honorable, and was only applied to seven persons. Rabbi was also looked upon as a higher title than rab. It is supposed that this title first came into use at the period immediately preceding the birth of Christ. In the time of our Lord it was applied generally to all religious teachers, and hence sometimes to Christ himself. Now the term *rabbi* is applied to regularly appointed teachers of Talmudic Judaism. Since 1831 these have in France been salaried by the state. Their duties are not only to give instruction in the Talmud, but also to draw up deeds of marriage and divorce, to examine butchers and to give their opinion as to what is legal and what is illegal in the Jewish ritual.

RABBINICAL LANGUAGE AND LITERATURE, that form of Hebrew in which the Jewish scholars and theologians of the Middle Ages composed their works. See JEWS AND JUDAISM — HEBREW LANGUAGE, JEWISH LITERATURE, ETC.

RABBINICAL LEGISLATION. See JEWS AND JUDAISM — THE SPIRIT OF RABBINIC LEGISLATION.

RABBIT, a name, when properly used, restricted to a single species (*Lepus cuniculus*) of the rodent family, *Leporidae*, to which the native American hares (q.v.) also belong. The rabbit is of European origin, and, although found wild in many places, is better known in the domesticated or semi-domesticated state in which it has been introduced into the United States. Although the habits of the rabbit afford the best distinction from the hares, the

wild species exhibits some structural characteristics, among which are its generally smaller size, the shorter ears of uniform brown color and the shorter limbs. The hind legs in the hares are proportionally longer than in the rabbits, and the eyes are larger and more prominent than in the latter animal. The face is also narrower and the skull lighter in the rabbit. The rabbit's fur in its native state is of a nearly uniform brown color, while under domestication the color may become pure white, coal black, piebald, gray and other hues. The texture of the fur also changes under domestication.

Unlike the hares, which construct only simple nests or forms, the rabbit lives permanently in underground burrows, large colonies of which are often to be found in some dry sandy bank overgrown with furze or brush, or other similar locality. Such "warrens" are often specially set apart for them in order that they may breed and multiply for the market, their flesh being excellent as food, and their fur and skins of value. The burrows are irregularly disposed, and communicate freely with each other. Rabbits are extremely prolific, and begin to breed when about six months old. They may breed six or eight times a year, producing from five to seven or eight at a birth.

The parturient rabbit excavates a special burrow or tunnel for herself in which to give birth to and shelter her progeny, the nest being lined by down plucked from her own body. The young are hairless when born and have their eyes closed. The eyes open about the tenth or twelfth day. These animals feed on tender grass and herbage, and sometimes do great damage to young trees by stripping them of their bark.

These animals grow exceedingly tame and domesticated, and may exhibit no small degree of intelligence. They are snared, taken by ferrets and nets or may be shot. Rabbits are subject to certain diseases, such as rot, parasitic worms and a kind of madness. The original home of the rabbit is believed to have been those parts of Europe and Africa around the western half of the Mediterranean, where it still abounds, but it is now widely spread throughout temperate western Europe, and has been conveyed by man to such distant lands as Australian colonies, Tierra del Fuego and the Falkland Islands. In Australia and New Zealand it has multiplied so enormously as to have become a serious pest to the colonists, causing immense loss and damage by eating up the pasture intended for sheep and cattle. Various methods of extermination have been tried against them, but as yet none have had more than a moderate success. Large numbers are now killed and exported as food, frozen or otherwise preserved, and millions of skins are annually shipped to Europe and the United States. In some parts of South and Central America, and especially in Jamaica, the domestic rabbit has been introduced and established in the wild state. Darwin records several cases where quite distinct races of rabbits have resulted from their isolation on islands. An Asiatic species (*L. hispidus*) is closely related to the European rabbit, and a so-called tailless rabbit (*Romerolagus*) has been described from the region of Mount Popocatepetl in Mexico. It is peculiar in the possession of well-developed clavicles. All the domestic breeds or rabbits

appear to have been derived from the feral species of southern Europe; and have been but little influenced by occasional crosses with hares. The Chinese, as early as the time of Confucius, appear to have bred rabbits for sacrificial purposes; and domesticated varieties were mentioned by classical Greek and Roman writers. The most noteworthy change under domestication has been the great increase in size and weight, the latter having been raised from three pounds in the wild rabbit to as much as 18 pounds in the Flemish giant. This variety is bred chiefly for food, but for this purpose is less esteemed than the Belgian 'hare,' so-called because of its large size and hare-like color, and the unfounded belief that it originated from a cross between the hare and rabbit. The qualities which recommend the Belgian variety for market breeding are its extreme fecundity, the ease with which it may be kept in confined quarters, its rapid growth, so that it is ready for eating in about four months after birth, and the similarity of flavor of the young to the wild rabbit. A wave of enthusiasm for Belgian hare breeding passed through this country a few years ago, but has largely subsided, though many large rabbitries continue to supply the cities, particularly in the West. Of the purely fancy varieties the lop-ear is the most remarkable; the external ears in fine specimens measure 23 or even 24 inches long and six inches wide. The Angora, which originated in Asia Minor, has the beautiful long, silky white hair peculiar to several animals of that region, and there and in parts of Europe is bred for its hair, which is clipped and woven into underclothes, etc. Other varieties are peculiar chiefly in color. For methods of breeding, etc., consult Knight, 'The Book of the Rabbit' (London 1889); Rayson, 'Rabbits' (London 1880); Carnegie, 'Practical Game Preserving'; for history, variations, habits, etc., Darwin, 'Animals and Plants under Domestication' (Vol. I, New York 1868); Palmer, 'Jack Rabbits of the United States' (Washington 1896); Reports of the Royal Commission of Inquiry on the Extirpation of Rabbits in Australasia, especially that of 1890.

RABBIT FISH, in the southern United States, a globe-fish (q.v.) of the genus *Lagocephalus*. In Bermuda and other islands of the middle Atlantic, a common market-fish, caught in deep water. It is a rather large, reddish brown escolar (*Promethichthys prometheus*), and owes its name to its prominent front teeth which resemble the incisors of a rabbit.

RABELAIS, François, frän-swä räb-ë-lä, French author: b. Chinon, Touraine, about 1483 (according to other authorities 1490 or 1495); d. Paris, 9 April 1553. Regarding his birth, parentage and early youth nothing definite is known. It is a fact, however, established by still existing documents, that in 1519 he was a member of the Franciscan order at Fontenay-le-Comte, in Poitou, and being at first freely permitted to study, acquired Arabic, Hebrew and Greek, and read omnivorously on almost all subjects. Eventually, however, the Franciscans came to distrust the new learning. Rabelais was deprived of his books, and in disgust fled the monastery. Shortly afterward, in 1524, he obtained permission of Clement VII to enter the Benedictine order; he moved to Maillezais,

but before long quitted this brotherhood also, and began to traverse the country under the habit of a secular priest. His biographers have found it difficult to follow him during this period of his life, but it seems that in his wanderings he cultivated all the sciences of the day, and especially philology, with assiduity, and that in this he exhibited powers of acquisition such as few have possessed before or since. In 1530 he was enrolled as bachelor in the faculty of medicine at Montpellier, where he lectured on Galen and Hippocrates in 1531-32, although it was not till 1537 that he obtained the degree of doctor. In 1532 he went to Lyons, where he published 'Manardi Epistolæ Medicinales'; 'Hippocratis Aphorismi'; and 'Testamentum Cuspidii' (1532). In the same year he also, probably, brought out the first germ of his 'Pantagruel' (1532), of which, according to his own account, more copies were sold in two months than of the Bible in nine years. He was made physician to the Lyons Hospital, and was a member of the Société Angélique, a coterie of scholars that had gathered around the workshop of Gryphius, the printer. The first dated edition of 'Pantagruel' came out in 1533. This first specimen of the power of Rabelais in the style that has rendered him famous has all the grotesque humor, amounting even to buffoonery, and the variety of marvelous adventures of his later works of the kind, but wants the delicate raillery, the sustained allegory and profound philosophy which most students of Rabelais find in the subsequent versions of 'Gargantua,' and still more in the last three books of 'Pantagruel.' The first part of 'Pantagruel' appeared under the anagrammatic pseudonym of Alcofribás Nasier, within a year or so after the first work, and its success was such that it passed through three editions in one year. Under the same pseudonym he also published in 1533 the first of a series of almanacs, of which now only a few fragments exist, and 'Prognostication Pantagrueline.' In 1534 he accompanied, probably as physician, Bishop, later Cardinal, Jean du Bellay, on an embassy to Rome. The result of this journey was an edition of 'Marliani Topographia Antiquæ Romæ' (1534). Not long after he is found again at Lyons, where the 'Gargantua,' as we now have it, first saw the light in 1535. Late in 1535 he was again at Rome with Du Bellay, and on this occasion obtained from the Pope absolution for having neglected to enter a Benedictine house and other delinquencies. It was granted in response to his 'Supplicatio pro Apostasia' (1535). In the year following he is known to have been practising his art at Paris, but his love of wandering had not yet ceased, and his place of abode for the next eight or nine years was as unsettled as it had been during any previous part of his life. From 1539-43 he appears to have been in the service of Guillaume du Bellay, the elder brother of the cardinal, and to have resided with him in Piedmont of which he was governor. In 1546 he was probably in Paris, when the third book of his 'Pantagruel' appeared. In this the fantastical and trivial adventures that crowd the previous books give place in a great measure to regular dissertations, in which all the great moral and social questions of the day are discussed with the gaiety and irony peculiar to Rabelais, and with a freedom that roused the

suspicion of the clergy, who endeavored to have it suppressed. The favor of the king secured the free publication of this book, but it was with more difficulty that a license was obtained for the fourth book from the next king (Henry II), who had succeeded Francis in 1547. A mutilated edition of this appeared surreptitiously at Lyons in 1547. The license to publish was not obtained till 1550, and it was only in 1552 that a complete and authentic edition of the book appeared. In 1549 he was again in Rome and a description of some court festivities appeared under the title 'Sciomachie' (Lyons 1549). Rabelais was installed in the cure of Meudon, which he had had bestowed on him by his former patron, Jean du Bellay, in 1553, and it is possible, though by no means sure, that he resided there chiefly during the remainder of his life, resigning two months before his death. He left at his death the whole of the fifth book of 'Pantagruel' in manuscript. Sixteen chapters of this appeared under the title 'L'Isle Sonante' at Lyons in 1562. The entire fifth book was not published until 1564. The original manuscript was discovered in 1840, ending a long controversy as to its authenticity. A sixth book was intended to be added, but there is only a fragment of it indicating its subject, 'Les Noces de Panurge.' His enemies busily pointed out impieties, and he once fled to Metz to escape danger. Rabelais was one of the first to give flexibility and finish to the yet rude and harsh language of his country. Boileau calls him *La raison en masque*, and Rousseau, *Le gentil maître François*. His house was the resort of the learned; his purse always open to the needy; and his medical skill employed in the service of his parish. His work cannot now be easily understood without a glossary and commentary. It has been widely regarded, especially in France, as a treasury of wisdom, wit and shrewd sense. See GARAGANTUA and PANTAGRUEL.

The first complete edition of the 'Gargantua' and 'Pantagruel' is that published by J. Martin at Lyons in 1567. During the next 30 years some 60 editions of one kind or another were brought out. Of later editions the most important are that of J. Le Duchat (Amsterdam 1711); the Variorum edition edited by E. Esman-gart and E. Johanneau (9 vols., Paris 1823-26); a splendid edition, illustrated by Gustave Doré and edited by Burgand des Marets and E. J. Rathery (2 vols., Paris 1857-58; 2d ed., Paris 1870); a seven-volume edition by P. Jannet (Paris 1873-74); a very carefully annotated edition by C. Marty-Leveaux (6 vols., Paris 1868-1903); and a one-volume edition by L. Moland (Paris 1881). A new critical edition by A. Lefranc is in preparation. There are English translations by Urquhart and Motteux (London 1653-94); new edition, in the series 'Tudor Translations' (3 vols., London 1900), and by W. F. Smith (2 vols., London 1893). There is also a good German translation by G. Regis (Leipzig 1832-41; new ed., Munich 1906). Selections in English will be found in Besant, W., 'Readings in Rabelais' (Edinburgh 1883); Stokes, F. G., 'Hours with Rabelais' (London 1905); Wright, C. H. C., 'Selections from Rabelais's Gargantua' (New York 1904).

RABIES. See HYDROPHOBIA.

RABINOWITZ, Solomon, Yiddish humoristic author, known best by his pen name "Scholem Aleichem": b. Kief, Russia, 1859; d. New York City, 13 May 1916. He began his career as a writer of short Yiddish stories in the Russian-Yiddish press. Because of the Kishineff pogroms, he came to the United States in 1906, and was received with great acclaim by his coreligionists. He returned later to Russia, where he met with pecuniary reverses, which were at once relieved by his many thousands of warm admirers. At the beginning of the European War, Mr. Rabinowitz, who was at a health resort near Berlin, was detained and finally sent to Denmark. He returned to the United States in December 1914, where he was again fêted and lavishly entertained. In the United States he wrote stories for the Yiddish dailies, many of which have been translated into English. He is best known for his sympathetic, kindly, humorous treatment of Ghetto life. His admirers in the United States have called him "the Yiddish Mark Twain."

RABSHAKEH, *rāb-shāk'ē*, an officer of the king of Assyria, mistaken in the Authorized version of the Bible for a proper name, but in fact an official title, probably that of a military commander. He is sent with Tartan and Rab-saris, also titles of high officials, to take a threatening message from Sennacherib to King Hezekiah. He delivers it in the Hebrew tongue, and when requested to use the Aramaic dialect, the language of diplomacy, so as not to alarm the people, he insolently refuses (2 Kings xviii-xix; Isaiah xxxvi-xxxvii). Consult commentaries on 1 and 2 Kings and the

book of Isaiah; also Schrader, 'Cuneiform Inscriptions and the Old Testament.'

RACCOON, the name, of Indian derivation, given to the typical members of the *Procyonidae*, a family of carnivorous mammals, resembling the bears in their plantigrade feet and other characteristics, but differing from them especially in the long tail, sharp snout, slender body and moderate size. All of the five or six known genera are confined to America, though the related Asiatic genus *Ælurus* is now placed here. (See PANDA). The members of the typical genus *Procyon* possess six incisors, two canines, eight premolars and four molars in each jaw, and the group is well exemplified in the common raccoon (*Procyon lotor*) which derives its specific name of *lotor*, "a washer," from its habit of washing its prey before eating it, or of holding the food in the fore paws and shaking it violently backward and forward in the water so as to moisten and saturate it as thoroughly as possible. The German name *Waschbär*, or "washing-bear" and the *raton* or *raton laveur* are also applied because of this curious habit. The raccoon is a heavily built animal, about three feet long, with a pointed snout, short ears and bushy tail alternately ringed with black and white. The general body color is a sooty or blackish-gray, and the fur consists of a close set of under hairs, with larger outer hairs, the latter being marked black and white. The upper part of the head and the portion across the eyes are colored dark brown. Throughout most of the United States the raccoon is abundant, and on the Pacific side reaches from Alaska to Central America. In spite of the settlement of the country and much persecution it generally holds its own, and in many sections is actually increasing in numbers. These animals, although typically carnivorous, yet seem to feed largely upon, and indeed to prefer, vegetable matters. In the natural state their food consists of all kinds of small birds and their eggs, mice, reptiles, frogs, crayfish, mussels, oysters, nuts, fruits, etc. Occasionally they catch fish or clear out a hen roost, and their frequent depredations upon fields of corn, of which they are very fond in the milk stage, has gained them the enmity of farmers. Raccoons are among the most strictly nocturnal of American mammals, and spend the day in sleep, usually in a hollow limb or tree trunk. During the winter they pass into an intermittent state of hibernation. About April, four to six young are born, which remain with the parents for a year or more, forming the small parties in which these animals are usually found. The raccoons are much hunted by means of dogs, which force the animal to take refuge in a tree, whence it is dislodged by climbing. The subtlety and cunning displayed by these animals in their endeavors to escape have become quite proverbial—expressions such as "sly 'coon," "wake as a 'coon," indicating these qualities. They are, however, very easily trapped, and when taken young make very gentle and interesting pets. They use their fore paws almost as expertly as a monkey its hands, and their great curiosity prompts them to investigate everything which attracts their attention. The agouara or crab-eating raccoon (*P. cancrivorus*) is found throughout South America. It is generally larger than the common species, the tail being

shorter, of a grayish-yellow tint, and marked with six black rings. The fur is blackish-gray, tinted with yellow, and of variable lights and shades over the different regions of the body. The eyes are surrounded by dark-brown patches, which run into the ears, and terminate in a patch on the top of the head. Although denominated "crab-eating," it does not appear to be specially addicted to this dietary.

Related genera are *Bassaris*, of which *B. astuta* extends from Mexico into the southwestern United States, *Nasua*, the curious arboreal coatis of Mexico and South America, and *Cercoleptes*, represented by the Central and South American kinkajou, which has a long protractile tongue. Consult Stone and Cram, 'American Animals' (New York 1902); Audubon and Bachman, 'Quadrupeds of North America' (New York 1851); Beddard, 'Mammals' (London 1902); Ingersoll, Ernest, 'Wild Neighbors' (New York 1897); Merriam, C. H., 'Mammals of the Adirondacks' (ib. 1893); Seton, E. T., 'Life Histories of Northern Animals' (ib. 1909); Stone and Cram, 'American Animals' (ib. 1914).

RACCOON-DOG, a small wild-dog-like animal (*Nyctereutes procyonides*) of eastern China and Japan, much resembling a miniature raccoon in appearance, especially about the head. It lives in burrows, gathers most of its food (fish, crabs, etc.) along the banks of rivers, and is frequently kept in captivity, especially among the Japanese, who also value its fur and eat its flesh. Its fur is long and grizzled, but handsome; its muzzle sharp, ears short and tail short and bushy. Consult Mivart, 'Dogs, Jackals, Wolves and Foxes' (1890).

RACCOON-OYSTER, a name in the Southern States for the small irregular wild oysters, growing numerously in the salt marshes, and much eaten by raccoons and other animals.

RACE, Cape. See CAPE RACE.

RACEME, *ra-sēm'*, in botany, a form of inflorescence in which the primary axis is elongated, and bears flowers placed on pedicels of nearly equal length, as in the currant. A raceme differs from a spike only in having the flowers being stalked, instead of sessile. See FLOWER.

RACER, BLACK RACER, or BLUE RACER, a blacksnake (q.v.), especially the common lowland one (*Zamenis constrictor*), so called from its swiftness.

RACES, Origins of. Any discussion of race is handicapped by four points of obscurity: firstly, there exists no very clear idea in the mind of many as to what constitutes race; secondly, the marks of differentiation which serve to set off one race from another are often vaguely presented; thirdly, there seems to be no very reliable knowledge concerning the number and the origin of races, and, finally, geographical location is not invariably clearly defined. To produce type a certain set of elements must persist generation after generation and to trace this type is to go backwards to the very dawn of mankind's awakening and to inquire what beings existed on the globe at that time.

Geology supplies that there were roughly three great periods, called, respectively, the Mesozoic, Tertiary and Quaternary, and that these corresponded with the development of

(1) reptiles and the rise of the flowering plants, (2) mammals and the appearance of modern plant life, and (3) man, that is, the prevalence of the Stone, Bronze and Iron Ages, comprising the extinction of the great mammals and the dawn of mind, art and industry. These facts may in essence reflect the zoological division of zoöphytes, mollusca, articulata and vertebrata, the last named being divided into reptiles, fish, bird and mammals, the crowning apex of which order is man.

Whether or not man is the ape himself, there stood, nevertheless, man (or many men, say the polygenists who conceive the world to have been peopled simultaneously at various spots on the earth's surface, thereby refuting the monogenists who hold to the "Biblical" original pair), with skull, stature, skin and hair, which elements are the *foci* upon which subsequent races and nations are to be differentiated and determined. That concerning the time of the Rough Stone Age, when fauna and flora initiated their appearance, little is known of man but the formation of his skull, the only remainder that could have come down to the present over a bridge of more than 100,000 years is evidenced in the single fact of the skull being of the nature denoted by scientists of enlightened days Neanderthal, that is, Cro-Magnon, dolichocephalic or long (the relation of the length of the head to its breadth is the formula upon which craniology orientates modern racial division). Yet even this fact of long-headedness among the olden men is not didactically vouched for. Archaeology in giving the rough outline of those unknown ages which, under the name of Stone, Bronze and Iron, comprised early rudiments of human life, the transition to shelters, the correlation of animal existence as, for instance, the presence of the woolly mammoth, rhinoceros, reindeer and cave bear in successive waves of existence, can, after all, only rely upon scant evidence such as produced from caves, *kjökken-møddings* (kitchen leavings), and pile villages.

Early life was characterized by the very rudiments of human activity. Hunting and fishing must have been followed by agriculture, and all these occupations demanded tools. This demand set man's inventive energy to work to grapple with the making of tools, fire and the bow and arrow. Decorating, weaving, the making of pottery and the domestication of animals were gradually learned. No division of labor could have occurred until after the formation of the state, however, for division is dependent upon organization and the centralization of a directive agency. The simplest and most isolated industry must have preceded the institution of trade, but that the associative element of trade must soon have begun to make itself felt is proven by the early occurrence of fairs. The making of homes presupposed some sort of marital condition necessary for the rearing of children, consequently promiscuous marriages, polygamy, polyandry and monogamy have variously characterized primitive family life. The importance of the family was indeed not to be gainsaid in early days, for to it can be traced the rudiments of state organization in such forms as the patriarchal family. In the patrymnic grouping can also be detected the early beginnings of religious observances. The wor-

ship of an ancestor antedated the rise of a priestly cult. With settled life, religion, associated in the mind of a savage with nature wonder, took its first definable form. Slower to evolve but betokening a higher degree of specialization than industry or religion in primitive life is politics. The establishment of a state marks a climax in the transition of society from primitive to civilized form. It is the note of difference between tribal and civil society, where conditions of increasing wealth and population demand systematic cultivation of agriculture and organized social life. Restlessness and lawlessness have to be overcome by the force of the state; a machine of government is organized and later towns grow up, considerations of citizenship and economic relations make their appearance. Upon economic relations are based science, commerce and invention and these relations become eventual factors for differentiating kinds of states.

That a nation resembles an individual in being formed of certain elements is undoubted. Social, psycho-physical and physical traits are present in each aggregate whole. One is a unit as the other is a unit. Individuals are units marked off and differentiated from each other by racial and national barriers, possessing, however, common intellectual, emotional, moral and physical faculties, therefore, participating in culture and civilization as a whole and expressing art, religion and literature.

The physical characteristics in forming the basis for classification of all mankind in great stocks, or varieties, or races, divide men into color classifications as, for instance, Deniker's division of white, yellow, reddish brown and black-skinned strains. Furthermore, hair may be straight, slank, wavy, spiral, frizzy, curly, woolly or fleece-like. It may be long or short. The color may range from pale blond through the ruddy shades to jet black. The correlations of body height and head index added to color defines racial characteristics more narrowly. Head index of all body characteristics the least changed under the mutable conditions of environment gives the final stamp to racial distinctions in its dolichocephalic and brachycephalic classifications.

Hair, skin, eyes, stature and head index are characteristics common to all men and on these points Europe, Africa, Asia and America can be classified. Over these continents are distributed the white, yellow, red and black-skinned races—black in Africa, red in America, yellow in Asia and white in Europe. The low-statured, black-haired Esquimaux may resemble the yellow-skinned Japanese in some points of classified likeness, yet that they should radically differ from the red-skinned American Indian or the black-complexioned African of New Caledonia bespeaks the existence of distinct marks which may be taken as representative of the continuity of a certain set of elements persisting generation after generation in spite of the passage of the years—which is essentially race in unit.

Sergi in classifying races principally according to cephalic index recognizes the Mediterranean district as the centre of dispersion of the European races, and consequently divides mankind into the Eurafian and Eurasian accordingly as the races have made their home

in Africa and Europe, or Asia and Europe. Subordinately Eurafrian stock is divided into two varieties, Mediterranean and Nordic. Eurafrian and Eurasian varieties are designated by Ripley Teutonic and Alpine Mediterranean. The Teutonic type is white-skinned, blond-haired, blue-eyed, narrow of head and tall of stature; the Alpine type is white-skinned, brown-haired, bluish-gray-eyed, round of head and mediumly tall; and the Mediterranean type is olive-skinned, dark-haired, dark-eyed, long of head and mediumly tall. These latter three racial strains form the centre of world activity at the present. Anglo-Saxon Teutons colonized and together with Alpines and Mediterraneans, reared and superimposed a state structure upon the red-skinned racial base of the North American continent. Mediterranean Spaniards, Portuguese and other Europeans have peopled the southern American continent. Dark-skinned Africans, chocolate-colored dwellers of the Pacific and slant-eyed inhabitants of the Celestial Empire are all pushed into obscurity by the battling pre-eminence of Teutons, Alpines and Mediterraneans.

The old law of conflict, savage tribe exerting its will on another savage tribe, is illustrated in subordination of one nation by another, of rising and falling powers, of destinies that wax and wane. In primitive form the subordination is physical, in the civilized it is ethnological, for language and customs are imposed instead of brute force.

Thus have the nations shifted, till to-day instead of unbroken areas of savage tribe, primitive hordes or the embryo state-formation of village life there are crystallized units possessing a common language, common creed and inspired by identical ideals of statehood. The fact that a people is thus massed together produces a certain unity—thus it is possible to speak of "the English" as a unit and mean a definite type. That the original Britons were dark and small of stature is generally supposed. After the dawn of history these primitive characteristics came to be identified with the traits of traders and invaders who visited the island, but who, anthropologically, were hardly important. Danes and later, Normans, were invaders, but unlike the Romans they changed the anthro-ethnological type of Britain, for they came to settle and perpetuate the race. The significance of this contact between two representative strains of the Teutonic stock should not be disregarded, for in it are perhaps to be discovered dynamic elements which were to contribute to the eventual rise to world power and physical superiority of one of the participating nations. The Normanizing of English affected language, government, church and nobility. The Norman Conquest is really the birth of England because it was the last of the invasions and paved the way for the working out of the homogeneity of a people. A state is based on homogeneity of race, compactness of territorial possession, religious cohesion and stability of government. But it is men who in the last analysis make a state, and when through the consciousness of the members of a state there runs a consciousness of kind, a feeling of like-mindedness and a sense of brotherhood, a state is evolved. Upon the utilitarian character of the Briton has been

built the great structure of England's commanding position in the world arena. Commercialism, based upon domestic security and an adequate financial foundation, has resulted in a growth of invention rapid enough to settle great industrial problems and a scientific outlook keen enough to maintain a trade which brooks no rival. The statehood behind all this is a state with a policy of common sense and resolution. England, unlike un-Teutonic countries, has made no great contribution to the heart of religion, she has rather contributed to the thinking powers of religion. Criticism and good taste are English churchly attributes. These qualities likewise characterize the Briton in art and literature, that is, cosmopolitanism.

On the other hand, what is most attractive in the life of the German strain of the Teutonic branch is what is most German. It is one of the most striking peculiarities of German culture that it delights in the pedantic substitution of what is vaguely cosmopolitan for what is native and of the soil. Yet the supremely cultivated man is not the man of pedantic encyclopedic knowledge, but the man who possesses the key to distinction of style, which is the finely culled result of scientific detachment and dispositional reposefulness.

Definite knowledge of Scandinavia's racial origin is lacking. The Neanderthal man of the paleolithic or diluvial period may be the foundation type of Scandinavian races as of other European strains. At any rate it is believed that two race strains, the Cro-Magnon or dolichocephalic and the Dissentis or brachycephalic types, have existed in Scandinavia for a very long time. During the Bronze and Iron ages there were men in Scandinavia who ploughed and tilled the soil. The waves of civilization which no doubt swept over Europe touched the northern countries as well and brought changes in industry and language. At the dawn of history two races were known to be existing in Scandinavia and till to-day there are two distinct strains to be observed in the population. History, however, has emphasized one type to the exclusion of the other, and the tall, fair, blue-eyed type has received the preponderance of attention.

That these fair-haired, blue-eyed Northmen were indeed quite similar to their kindred of the other Teuton districts is proved by the fact that great similarity characterized the tongues of the respective countries in the earliest of Saxon times. Not only could an Icelandic bard be understood in Norway, Denmark and Sweden but also by Frisians in England, for the root dialect of English as well as Norwegian, Danish and Swedish belongs to the Teutonic branch of the Indo-European stem, according to Prof. Max Müller. The Frisians in coming to Britain brought their Low German dialect with them. The Scandinavians, using another but related dialect, gradually built up their separate philological system, as the English eventually did theirs. Dialect precedes language, as tribes, clans and families precede the state. A language grows by stages, there is the composition of roots, the gradual discernments of meanings and the systematic elaboration of grammatical forms. In the old Eddas of Iceland and the Beowulf of Britain great resemblances of speech are to be found. Nevertheless, with the

passage of time differentiation sets in and new forms are evolved. The Norman tongue, which was the Norse dialect Latinized, came to England to mix with the old Frisian Low German, and a new language eventually to be called English sprang into existence.

Thus, the ruddy, fair-haired Englishman is akin to the tall, blond Swede, and the short, dark Welshman is akin to the broad-headed Dane in the respect that in the beginning all have had a common ancestry and ethnological breeding. That one can go farther and say that from these similarities other similarities result is doubtful. True as it is that Scandinavians agree in reproducing Teutonic type identically with the English in some respects, in the Protestant form of religion, in the nature of their government and in their common qualities of love of independence, self-reliance, common sense and in their allegiance to the principles of logic, nevertheless in many other respects these two representatives of the one type do differ strikingly.

Anthropologically distinct from the Teutonic type is the Slavic, Celtic or Alpine type. Differing not only in stature and coloring but markedly in head index, this second type has, in contradistinction to the Teutonic, its own location and geographical setting. It is the Eurasian race mentioned by Sergi, or the Alpine by Ripley, and in ethnological terms it is called the Celtic race. Its habitat is, broadly speaking, northwestern Asia and central Europe. Its representatives are in the Slav nations, Russia and South Slavic states, Serbia, Rumania, Montenegro, etc., also Switzerland, France and Belgium. Anthropologically distinguished, the type is broad-headed, with eyes of blue or gray. Unlike as are the nations included in this type, nevertheless, distinguished from the other extremes, the tall, fair and long-headed Teutons and the short, dark, swarthy Mediterraneans, they are easily recognized to belong to an intermediate type.

France and Russia may serve to represent the second or Alpine race. Unlike in some anthropologic, ethnographic and sociologic respects, these nations nevertheless have certain bonds in common. In regard to the anthropologic type, there is a likeness of components rather than of wholes, for it is to certain strains in one that the other agrees. As to historic evidence of the men who lived early in Gaul and on the Russian plains, it may be said that Gaul was inhabited by what in ethnology are called Celts, broad-headed individuals who were mediumly tall; in Cæsar's first conquest of the Gauls he found such men called Belgæ, Gauls and Iberians, and Tacitus wrote of the Scythians living in the Carpathian Mountains. But both of these Alpine districts were also to be intermixed with Teutonic strains, France with the Burgundians, Visigoths and Franks, and Russia with the Swedes migrating from the north and touching Novgorod on their itinerant trail to Constantinople. Consequently, to-day Teutonic elements are found in both the Russian and French nations.

But it was long before the evolution of the finished French and Russian states that these events took place, and in the East the mixture

was destined to become increased to a yet greater extent before the real Russian nation was evolved. The early history of Russia is briefly told: the patriarchal family, the growth of the towns, the rise of the early cities of Kiev and Moscow, the growing power of the Coyars and of the princes, and the final concentration of power in one prince at Moscow, constitute the account. Early history thus politically told must also note the great anthropologic changes which have played a rôle in Muscovite history, that is, the Finnish and Tatar inroads which have been made upon Russian unity. Finns from the north came down to what is now known as Letto Lithuania. Tatars from the East, Chinese Tatars, sweeping over the immense Russian plains, brought an Asiatic influence which was to affect Russia, but sociologically and ethnographically more than anthropologically.

Foreign traits thus contributing to disposition, character and type of mind distinguish the Russian people from the Teutons on one side and from their fellow Celts, the French, on the other.

The French type is convivial in character and creative in disposition. The French social traits of hospitality, desire to please, humor and extravagance show their conviviality. These character traits are governed and held in check by the creative power in the French disposition, which seeks thrift and the adaptability of means toward end. Furthermore, in the sphere of morals the possession of a distinct power, the will, distinguishes French from Russian personality. It is will power applied to the vanquishing of acceptable odds, however, rather than to the overturning of repelling obstacles. The rationalism of the Teuton is absent. Intellectually, thinking approaches the Latin or Mediterranean type, for it is deductive. Unlike the Saxon common sense thinking, there is a tendency to intellectualize for intellect's own sake which verges upon the dreaminess of the South.

Although all the western districts bordering the Mediterranean Sea repeat the Mediterranean type, it is to Italy particularly that we look for the greatest historical and cultural manifestations of this type. And yet Italy itself constitutes an anthropological problem. By whom was it peopled and how was it settled? Many theories are offered in explanation. Three contrasting theories of original Italian type have been advanced. The Teutonic Aryan has been said to be the foundation type, also the Scythian or Slavic origin has been suggested, but Sergi holds to an original Mediterranean type.

Physically the Mediterranean figure possessing a dolichocephalic head index, short stature and dark hair and eyes is accepted as the usual Italian individual. Italian disposition is a combination of the aggressive and instigative—aggressive as old Rome was aggressive and instigative as have been the cabals and political intrigues from the days of Lorenzo the Magnificent to the modern age. In character as well as in disposition the Italian personality is a compound of two blends, austere and convivial—austere as were the old law-making administrative magistrates, convivial as the beauty-loving Italian is convivial. As Italian

disposition and character are complex so is the type of mind. The calm, appraising quality of Italian judgment is combined with the hot impulsiveness of emotion, a combination which makes the Italian a past master in the art of revenge, vengeance, cabal and intrigue. As with all Latins, so with Italians, commerce plays a subordinate rôle to art. It is in the sphere of emotion, morals and intellect that Italy has won her great sociological achievements, namely, art and the Church. More productive in the realm of art than the Celt, and more productive in the realm of religion than the Teuton, the Mediterranean personality yet falls behind the Teuton in creative expression of governmental talents.

Thus have the nations developed and specialized till to-day instead of physical entities such as wandering primitive men and woolly mammoths roaming the earth's surface, there are definitely marked national aggregates: England, a crystallized unit of people, described in type as tall, fair-haired, long of head and light of eyes, possessing an emotional life which is balanced and logical, an intellectual type of mind which is inductive and reasoning, a capacity for commerce and industry; a France that is temperamentally, artistically creative, contributing more to literature and art than to church or state; an Italy, cool and logical, contributing more to the heart than to the head of religion. Akin to the Italian Mediterraneans, the Spaniards of the American continent vie with that related strain and yet partake of the Teutonic qualities of the North American continent, recreating in the western section of the globe the commerce and industry of the European Teutons, and coming to endure along with the clearly inductive, boldly logical and successfully worldly Teutons the absence of the introspective and dreamy quality of the emotionally constituted Latins and Slavs.

B. L. STEVENSON,

Author of 'Socio Anthropometry: an Inter-racial Critique.'

RACHEL, in Bible history, the second daughter of the Aramaic cattle-owner, Laban. Jacob obtained her as wife by devoting 14 years to the service of her father. At the end of the first seven years he found in his veiled bride not the Rachel promised, but Leah, her elder sister, whom he did not love, and was obliged to serve seven years more in order to gain Rachel. She was the mother of Joseph and Benjamin, the birth of the latter causing her death. Her story is told in Genesis, especially in chapter xxix. Her so-called tomb, the authenticity of which, however, is very doubtful, stands to this day on the road between Jerusalem and Bethlehem and is held in the highest veneration by both Jews and Mohammedans. Consult Archer, W., 'Rachel of Padanaram' (London 1843).

RACHEL, râ-shêl (ELISHA RACHEL FÉLIX), French tragédienne: b. Mumpf, canton of Aargau, Switzerland, 28 Feb. 1820 or 21; d. Le Cannet, Provence, 3 Jan. 1858. Her father was an Alsatian Jew, naturalized in France, and after much wandering about Europe in his trade of peddling established his family at Lyons, where the two oldest children, Sarah and Rachel, sang and begged in the streets and in cafés to help out the family support. About 1830 they removed to Paris and the two girls sang on the boulevards until discovered by Etienne Choron, teacher in the school of Sacred Music, who undertook to teach them singing. Rachel's voice was found to be too harsh for this, and in 1834 Choron induced his friend, Saint Aulaire, to train her for the stage. On the advice of M. Samson she entered the Conservatoire, where, however, her harsh voice and small stature seemed at first against her. She made her début in a play called 'La Vendéene' at the Gymnase in 1837. The next year she joined the company of the Théâtre Français and made her first appearance as Camille in Corneille's 'Horace' 12 June 1838. She appeared in several parts successively and finally repeated in September her performance of Camille, was seen and applauded by the powerful critic of the *Debats*, Jules Janin, and her position established. After appearing in other parts in the French classic drama with increasing success, she visited England in 1841 and again in 1842, repeating her triumphs there. Later while still supreme at the Théâtre Français she made visits to other European cities, and in 1855 appeared in America. Here her success was only moderate, owing to her unfamiliarity with the language. A severe cold caught during her American tour ended in a consumption, from which she died at Le Cannet in the south of France. She was buried in the Jewish part of the Père Lachaise in Paris. Her great reputation was made in five or six rôles of the ancient classic drama of France, of these Phèdre being accounted her greatest. In the course of

her career she created 13 modern rôles, written for her, 'Adrienne Lecouvreur' alone of these still holding a place on the modern stage. She appeared in several other modern rôles that had been acted before her representation. She excelled especially in the impersonation of evil passion. Both her voice which through careful training had been changed from its former harshness to remarkable flexibility and melodiousness, and her restrained majestic acting, resulted in a rendition of her parts which was as perfect as it was thrilling. Consult B., *Madame de, 'Memoirs of Rachel'* (New York 1858); Beauvallet, L., *'Rachel and the New World; a Trip to the United States and Cuba'* (New York 1856); Darcie, J., and Corbin, W., ed., *'Mlle. RACHITIS. See RICKETS.

RACHMANINOV, räk-mā'nē-nōf, **Sergei Vasilyevitch**, Russian composer and pianist: b. government of Novgorod, April 1873. He entered the Conservatoire at Saint Petersburg at the age of nine, and in 1885 went to Moscow to study at the Conservatoire there, specializing on the pianoforte. His masters for piano were Zvierev and Siloti, pupils of Tschaiakowsky, Liszt and Rubinstein; and for composition and theory he studied under Taneiev and Arensky. He was awarded the Conservatoire's gold medal for composition in 1892, and went on an extended concert tour of Russia. In 1893-1903 he was professor of piano at the Maryinsky Institute for Girls at Moscow, meantime acting as conductor at the Moscow Private Opera in 1897-99; and appearing in London in 1899 at the Philharmonic Society's concerts, where he distinguished himself as composer, conductor and pianist. He conducted the Moscow Imperial Theatre in 1904-06, and afterward devoted himself to composition and concert tours in Europe and America. His work is strongly influenced by the Moscow school, and is splendidly characteristic and rich in variety and color. He is regarded as one of the foremost living Russian composers. He is author of many songs and choruses as well of piano pieces, of which his 'Prelude in C Sharp Minor' is especially well known and characteristic. He has written three operas, 'Aleko'; 'The Nigardly Knight'; 'Francesco da Rimini'; two symphonies, three concertos, the 'Elegiac Trio,' in memory of Tschaiakowsky, much chamber music and miscellaneous compositions.

RACINE, Jean Baptiste, zhōn bātēst rā-sēn, French dramatist: b. La Ferté-Milon, Picardy, 21 Dec. 1639; d. Paris, 21 April 1699. He studied at the College of Beauvais, and subsequently at the Port-Royal Institution, where, under the care of Lancelot and Lemaistre, he became a profound Greek scholar. In 1658 he left the Port-Royal, and began the study of philosophy at the Collège d'Harcourt at Paris. To this period belong his first literary

efforts, and ode called 'Nymphes de la Seine,' composed in honor of Louis XIV's marriage, and for which he was rewarded by Chaplain, then the dispenser of the royal bounty; and two comedies, now lost. About the same time he became intimate with La Fontaine, and this intimacy was so far from tending to make his life more regular, that those of his relations who took most interest in him, and who had destined him for the Church, began to be anxious about his prospects. In 1661 he went to live with an uncle, a canon-regular and vicar-general of the cathedral at Uzès (department of Gard), whose influence it was expected would suffice for procuring him a benefice. In this last particular they were disappointed; and at the end of about two years, during which Racine had been vainly endeavoring to study theology, he returned to Paris and the world. In 1663 he was presented at court, and soon made the acquaintance of Boileau and Molière, and began to write for the stage. His first tragedy, the 'Thébaïde,' was first performed by Molière's troupe at the Palais-Royal in June 1664, as was also his next, 'Alexandre le Grand' in 1665. His first two tragedies were merely tentative pieces, containing but few indications of the author's dramatic genius. His first master-piece was 'Andromaque,' which on its performance in 1667 produced a profound impression and excited well-merited admiration. It was brought out at the Hotel de Bourgogne, Racine having in the meantime quarreled with Molière. The immediate successor of 'Andromaque' was a comedy (Racine's only extant comedy), 'Les Plaid-eurs,' a witty and delightful imitation of the 'Wasps' of Aristophanes. It appeared in 1668, and was at first rather coldly received, being indeed saved only by the laughter of the king. His next pieces were 'Britannicus' (1669); 'Bérénice' (1670), composed at the request of Henrietta of England, who had also invited Corneille to write a drama on the same subject; 'Bajazet' (1672); 'Mithridate' (1673); 'Iphigénie' (1674), considered by Voltaire the greatest work that the French stage has produced; 'Phèdre' (1677), the last piece that Racine produced expressly for the theatre. Little is known of the private life of Racine during this period, almost all his correspondence having been burned from a too pious respect for his memory. In July 1673 he obtained a seat in the French Academy. In 1675 he was nominated by Colbert a royal councillor and treasurer of France for the general government of Moulins (Bourbonnais), but never entered on the duties of his office. His withdrawal from the theatre in 1677 was partly due to chagrin at the success of a hostile party of theatrical critics who set up for being fine wits and applauded one Pradon, a writer now never heard of, at the expense of Racine. Soon after (1678) he was appointed, along with Boileau, historiographer to the king, whom he accompanied in his campaign in Flanders. About this time Racine became reconciled with his relations and former friends at Port-Royal. His marriage belongs to the same period. It was happy and resulted in the birth of seven children. From then on Racine played, with considerable success, the part of a courtier. After a silence of 12 years Racine, at the solicitation of Madame de Maintenon, added two other pieces to the

list of his dramatic works—'Esther' (1689) and 'Athalie' (1691), the latter often spoken of by French critics as the most perfect of his works. They were both intended for the pupils of Saint-Cyr, the institution founded by Madame de Maintenon. The death of Racine is said to have been hastened by grief at losing the favor of the king. As a dramatist Racine is usually considered the model of the classical or national tragic drama of the French and in estimating his powers in this field it is necessary for the critic to take into account the stiff conventional restraints to which that drama is subjected. What Racine achieved within these limits is extraordinary. He added to the conventional drama as he received it a grace of which one would not have deemed it capable; he was greater as a poet than as a dramaturgist, and wrote in a style of finished perfection and distinction, developing French versification to its ultimate of rhythm and dignity. In his restraint, proportion, balance, he is rightly regarded as classic. "Perhaps it would be no exaggeration to assert," says Dowden, "that grandeur and beauty are nowhere else so united in French dramatic art as in 'Athalie.'" Besides his dramas Racine wrote several stinging epigrams, some odes and hymns, an abridgment of the history of Port-Royal, letters and historical fragments on the campaigns of Louis XIV. Among his letters are two in reply to a work of Nicole of the Port-Royal, entitled 'Les Visionnaires' (1666), in which the author bitterly denounces poets and still more dramatic writers. The tone of these letters is severely sarcastic and naturally caused great offense to his old friends and masters. Only one of the letters was published at the time they were written, the other after his death. After his retirement from the theatre Racine found it easy, as has been said, to reconcile himself with his old friends. See *ATHALIE*; *PHÈDRE*.

The first collected edition containing nine tragedies then written was published in 1675-76; another containing practically all of his important works appeared in 1697. Both are in two volumes. Since then there have been almost innumerable editions of varying perfection. Among these one of the best is that published at Paris in three volumes (1801-05), regarded as a marvel of typography. An excellent edition of 'Œuvres Complètes' was published in 10 volumes in 1865-73 in Hachette's collection of the 'Grands Ecrivains de la France,' preceded by an admirable essay on Racine and his time by Paul Mesnard. There is an English metrical translation by R. B. Boswell (2 vols., London 1913). Most of his tragedies have also been translated into many other languages and have found many imitators, some of whom, however, succeeded in reaching Racine's perfection. Consult Beyle, M. H., 'Racine et Shakspeare' (Paris 1854); Blaze de Bury, M. P. R. S. 'Racine and the French Drama' (London 1845); Canfield, D. F., 'Corneille and Racine in England' (New York 1904); Deschanel, E. A. E. M., 'Racine' (2 vols., Paris 1891); Gavaunt, P., ed. 'Conférences de l'Odéon' (Paris 1916); Larroumet, G., 'Racine' (Paris 1898); Lemaître, J., 'Jean Racine' (Paris 1908); Masson-Forestier, A., 'Autour d'un Racine Ignoré' (Paris 1910); Monceaux, P., 'Racine' (Paris 1892); Morgan, J. P., 'Catalogue of Racine Collection' (London 1906); Racine, L., 'Mémoires

de Jean Racine' (Lausanne 1747); Roy, J. J. E., 'Histoire de Jean Racine' (Tours 1863); Sainte-Beuve, C. A., 'Port-Royal' (7 vols., Paris 1908); Stapfer, P., 'Racine et Victor Hugo' (Paris 1894); Trollope, H. M., 'Corneille and Racine' (in 'Foreign Classics for English Readers,' Edinburgh 1881).

RACINE, Louis, French poet and critic, second son of Jean Racine (q.v.): b. Paris, France, 6 Nov. 1692; d. there, 29 Jan. 1763. He was deeply religious and after the death of a favorite son practically retired from the world. He attained considerable attention as a poet and critic though manifestly under a disadvantage as the son of so eminent a father. His poems 'La Grâce' (1720) and 'La Religion' (1742) were highly praised and the latter ran through 60 editions. He also wrote a number of odes, chiefly of a religious character. His prose writings include 'Réflexions sur la Poésie' (2 vols., 1742); 'Mémoires sur la Vie de J. Racine' (2 vols., 1747); 'Remarques sur les Tragédies de Racine' (3 vols., 1752). A volume, 'Poésies Fugitives,' published over his name in 1784, was repudiated by his widow and friends. He also published a prose translation of Milton's 'Paradise Lost' (3 vols., Paris 1755). Of his various writings only 'La Religion' has been translated into English (London 1754). His complete works were published in six volumes in 1808. He was made a member of the Académie des Inscriptions in 1719. Consult De la Roque, A., 'Vie de Louis Racine' (Paris 1852).

RACINE, Wis., city, county-seat of Racine County, on Lake Michigan at the mouth of Root River, and on the Chicago, Milwaukee and Saint Paul and Northwestern railroads, about 22 miles south of Milwaukee and 65 miles north of Chicago. It has steamboat connections with all the lake ports, and electric lines extend to all the nearby towns. It is 40 feet above the surface of the lake, and 690 feet above sea-level. It was settled in 1834; in 1843 was incorporated as a village, and in 1849 as a city. Racine has one of the best harbors on the lake. It is the commercial and industrial centre of a productive agricultural region about midway between Milwaukee and Kenosha. There are many creameries and an extensive lumber and coal trade is carried on. The chief manufacturing establishments are knitting mills, machine shops, flour and lumber mills, carriage factories, foundries, boot and shoe factories, tanneries, valise and trunk factories, steel spring works, hosiery mills, furniture factories, breweries, plating works and woolen mills. The products from other manufactories are bedding, men's clothing, paints, mangles, fanning mills, wind-mills, bicycles, bits, sheet iron, brass and copper goods, iron specialties, malted milk, chemicals, soap and other articles. The manufacturing interests are steadily increasing; it is the second city in the State in the value of its manufactures. In 1910 the capital invested in its 142 industrial establishments, employing 10,354 persons and having an annual payroll of \$6,679,000, was \$36,326,000, and the value of the output was \$24,673,000. The prominent public buildings and institutions are the government building, the county courthouse, the municipal buildings, Saint Luke's Hospital, Saint Mary's Hospital, Taylor Orphan Asylum and the Dominican

Corivent. The educational institutions are Racine College (P.E.), founded in 1852, the Racine Grammar School (P.E.), Saint Catharine's Academy (R.C.), a public high school, public and parish schools, a public library, two libraries connected with Racine College and the Y.M.C.A. library. In 1915-16 the total enrolment in its 191 public schools was 7,575 pupils who were instructed by 249 teachers. Racine, in 1918, had seven banks, three of which were national, with a total capital of \$950,000 and deposits of \$10,502,000. There were also two daily and three weekly newspapers, one each of the latter being English, German and Danish. In 1910, of the total population which in 10 years had increased over 30 per cent, only 112 were negroes. About 33 per cent of the white population, 12,509, were foreign born, chiefly in Denmark, Germany, Russia, Austria-Hungary and Great Britain and its colonies.

The government is administered under a revised charter of 1905, which provides for a mayor, who holds office two years, and a council. The mayor appoints the fire and police commissioners and, subject to the approval of the council, the members of the board of education. In 1914 the total receipts were \$1,491,259; the expenditures for all purposes, \$1,317,864; the assessed value of real estate and personal property, \$49,759,719; the tax rate, \$13.52 per \$1,000; the funded debt, \$940,000, less a sinking fund of over \$10,000. The city has 12 parks, three playgrounds, some public beaches and 35 miles of paved streets. Pop. about 38,002. Consult Anon, 'History of Racine and Kenosha Counties, Wis.' (Chicago 1879); Leach, E. W., 'Racine County Militant' (Racine 1915).

RACING. See HORSE-RACING.

RACK, an instrument of torture in frequent use in the Middle Ages, and down to a comparatively recent period. It is not known to have been used in the American colonies settled under British rule, but it is among the ancient instruments of torture preserved at Montreal as relics of French rule in that country. The rack consisted of a large, open, wooden frame, within which the person to be tortured was laid on his back on the floor, with his wrists and ankles fastened by cords to two bars at the ends of the frame. These bars were then drawn or moved by means of levers and pulleys in opposite directions till the body rose to a level with the frame. Interrogations were then put, and if the prisoner refused to answer, or if his answers were not considered satisfactory, the rollers were further moved, until at last the bones of the sufferer were forced from their sockets. The rack was also used simply for purposes of punishment, apart from desire to extort a confession. According to Coke it was introduced into England in 1447 by John Holland, Duke of Exeter, who was at that time constable of the Tower of London, hence its name "the Duke of Exeter's daughter." The question of the legality of the use of the instrument was raised when the Privy Council attempted to put John Felton, the murderer of the Duke of Buckingham, to the rack that he might be made to disclose the names of his accomplices. The judges, however, resisted, declaring the proceeding unlawful. The rack was

also used in other European countries, by members of the Inquisition.

RACKETS, or **RACQUETS**, a game played in a prepared court, open or close, with a small hard ball and a kind of bat. The bat is about two feet in length, about two-thirds of which forms the shaft or handle, the remainder being an oval frame on which is tightly stretched a net-work of cat-gut. The part of the shaft by which the bat is held is covered with leather and ribbed, to enable the player to grasp it firmly. It is from this bat and the net-work, which is its principal feature, that the game derives its name (Italian, *racchetta*, for *retichetta*, an old diminutive of *rete*, Latin and Italian, a net; French, *raquette*). The close, that is, roofed court, is now generally preferred. It is an oblong rectangular space, and when of full dimensions is 80 feet long, 40 feet broad and has walls 40 feet high. The players stand facing one of the narrow walls, which is called the front wall. Two horizontal lines are drawn across the front wall, one two feet two inches, and the other, the out or service line, eight feet above the floor. The surface between the floor and the lower of these lines is covered with wood, which serves as a sounding-board to enable the players to know when it is struck by the ball.

The game may be played either single or double, that is, with either one or two persons on each side. It is decided by lot which side goes in first, and when there is only one player on each side the first player assumes which side of the court he pleases (usually the right), while the other stands in the opposite corner. The first player then begins to *serve*, in doing which he must have one foot in the service box of his side. Service consists in striking the ball with the bat so as to make it strike the front wall above the outline without previously striking any other part of the court, and then rebound into the opposite corner beyond the short line. In rebounding from the front wall it does not matter whether the ball strikes on the floor in the opposite corner of the court. If the ball is properly served the second player must strike it before it has made a second bound, so that it strikes the front wall above the board; but in returning the ball in this manner the player may if he likes first make it strike either of the side walls. The player to whom a ball is served does not require to wait till the ball has bounded from the floor before he returns it. He may return it before it touches the floor. Such a stroke is called a volley. The ball being thus returned by the second player, the first player returns the ball in the same way, and this goes on until either player fails, which may happen in three ways, either by the ball being made to hit the sounding-board, or being struck into the roof or gallery, or later than the first bound. If it is the first player who fails, his hand is out, and it is then the turn of the second player to serve. If it is the second player, then the first scores one (an ace), and the first continues to serve, but goes to the opposite side of the court. The other details of the game must be derived from the rules drawn up by the different racket clubs. Consult Miles, E., 'Racquets, Tennis and Squash' (London 1902); *Spalding Athletic Handbooks* (New York, annually); Thompson, F. C., 'Court Tennis, with

Notes on Rackets and Squash-Rackets' (Philadelphia 1909).

RACOVIAN CATECHISM, the catechism of Rakow, Poland, where it was originally printed and published in 1605. It contained a popular exposition of Socinianism. There were two such catechisms, a smaller and a larger, both afterward published in Germany by Smalcus, the former in 1605, the latter in 1608. In 1652 John Biddle translated the larger of the two into English. Parliament, on 2 April 1652, ordered all printed copies to be burned. A new English edition was brought out by T. Rees (London 1818).

RADANTZ, ră'donts, Austria, city of Bukowina, 35 miles by rail southwest of Czernowitz. It has a cathedral dating from 1402, and the 15th century monasteries of Putna and Succawica are located near the town. The Austrian government maintains a stud of about 1,500 horses here. There are manufactories of paper, leather and machinery. The population is about 70 per cent German and 25 per cent Rumanian. Pop. about 26,084.

RADCLIFFE, răd'klif, Ann Ward, English novelist: b. London, 9 July 1764; d. there, 7 Feb. 1823. She was married at 23 to William Radcliffe, afterward editor and proprietor of the weekly called *The English Chronicle*. Her first work was 'The Castles of Athlin and Dunbayne,' a Highland story (1789). It had little success, but perhaps as much as it deserved. 'A Sicilian Romance' (1790) is superior to it, and 'The Romance of the Forest' (1791), a still further advance, was dramatized and translated into French and Italian. Her masterpiece is considered to be 'The Mysteries of Udolpho' (4 vols., 1794), which was long very popular, and was translated into French. The last of her novels published during her life was 'The Italian, or the Confessional of the Black Penitents' (3 vols., 1797), a romance of the Inquisition, which was dramatized as 'The Italian Monk,' and translated into French by Morellet. The dramatization, very inferior to the original, was produced at the Haymarket, London, 15 Aug. 1797. A posthumous romance, 'Gaston de Blondville,' together with some poems (4 vols.), though written in 1802, was not published until 1826. It, too, was translated into French. A small volume of verse, published first in 1816 and reissued in 1834 and 1845, contained poems inserted in her various novels, was brought out by an anonymous editor and contains also some inferior poems of the latter. Another work of hers was 'A Journey through Holland and Germany' (1795). A collected edition of her novels with an appreciative preface by Sir Walter Scott was brought out in 1824. After the publication of 'The Italian,' Mrs. Radcliffe practically retired from the world, though the frequently reiterated story that she had become insane has no foundation, in fact. Mrs. Radcliffe's novels were at one time very popular. In a way she may be regarded as the founder of a new school of English novelists, but none of her followers and imitators even equalled her in imagination and ability in devising supernatural events followed by natural explanations. She had considerable power in the description of scenery, and well understood how to excite and maintain the curiosity of her readers. She

was perfect mistress of the mysterious in romance and the first English writer of note to introduce descriptions of scenery into fiction. (See MYSTERIES OF UDOLPHO). Consult Beers, H. A., 'A History of English Romanticism in the 18th Century' (New York 1899); Howells, W. D., 'Heroines of Fiction' (Vol. I, p. 79, New York 1901).

RADCLIFFE, John, English physician: b. Wakefield, 1650; d. Carshalton, Surrey, 1 Nov. 1714. He was educated at University College, Oxford, was a Fellow of Lincoln College, 1669-77, graduated in medicine in 1675 and, at Oxford, began the practice of medicine, but removing to London in 1684 soon established a large practice which he maintained, it is said, more by his witty conversation than his medical skill. In 1686 he became physician to the Princess Anne of Denmark, and frequently attended William III after his succession. His bluntness of speech lost to him the favor of Princess Anne and later of King William, though he continued to number many of the nobility among his patients and prescribed for Pope and Swift. He was made a Fellow of the College of Physicians in 1687, acted for many years as governor of Saint Bartholomew's Hospital and in 1690 and 1713 was elected to Parliament. His learning was often depreciated; but he seems to have been an acute observer of symptoms and his immense practice gave him a wide field for observation. By his will, property was left in trust for the foundation of two medical traveling fellowships, and for the purchase of perpetual advowsons for members of University College. He also left money for the erection of various public buildings, among which was £40,000 for the public library in Oxford, since called the Radcliffe Library. From estates left in trust to the executors to administer for charitable purposes according to their judgment were built the Radcliffe Infirmary, the Observatory at Oxford and enlargements to Saint Bartholomew's Hospital. Later money was granted toward the buildings of the College of Physicians in London, the Oxford Lunatic Asylum and Saint John's Church, Wakefield. His prescriptions were collected and published by E. Strother, as 'Pharmacopoeia Radcliffeana' (2 parts, London 1716). Consult Macmichael, W., 'The Gold-headed Cane' (New York 1915); Pittis, W., 'Dr. Radcliffe's Life and Letters' (London 1715).

RADCLIFFE, England, an urban district, in the county of Lancashire, seven miles northwest of Manchester, on the river Irwell and on the Lancashire and Yorkshire Railway. The ancient parish church of Saint Bartholomew dates from the time of Henry IV. There are cotton and calico works, bleach-fields, dyeing establishments, iron foundries, machine and paper factories and extensive collieries in the vicinity. Pop. 25,692.

RADCLIFFE COLLEGE, a college for the education of women, affiliated with Harvard University, Cambridge, Mass. Its forerunner was the Society for the Collegiate Instruction of Women, organized in 1879 to provide systematic instruction for women by professors and instructors in Harvard. This society was incorporated three years after its organization, and its educational work proved so successful that in 1894 it was formally affiliated with the

university. At that time the name of the society was changed to Radcliffe College, power to grant degrees was conferred and the president and fellows of Harvard University were constituted the board of visitors of Radcliffe, which should have supervision over the administration of the affairs of the college, the granting of degrees, the appointment of instructors, etc. All diplomas given by Radcliffe are countersigned by the president of Harvard and bear the university seal. Most of the courses of study are identical with the Harvard courses, and graduate students are admitted to some of the graduate courses of the university. The courses are divided into three groups in the different branches of study: (1) courses primarily for undergraduates; (2) courses for graduates and undergraduates; (3) courses primarily for graduates. Courses in Semitic languages and history, history and theory of education, pedagogy and the history and theory of art and music are included in the curriculum. The degrees of A.B., A.M. and Ph.D. are conferred. There are two fellowships, one for the promotion of the study of Greek history, literature, art and archaeology at the American School at Athens, and one for the promotion of the study of social problems at a settlement house in Boston; there are also 54 scholarships and a number of prizes. The college has laboratories of physics, chemistry, zoology and botany, a gymnasium, dormitories, etc.; the library numbered 35,323 volumes in 1918; the Harvard University library and museums are also opened to students of Radcliffe; in 1904 a new hall fully equipped with auditorium, club rooms, etc., was built. The students in 1918 numbered 665 and the faculty 147. Le Baron Russell Briggs of Harvard University was appointed president in 1903. In 1918 income producing funds amounted to \$1,045,000 and the total income was given as \$102,340. Since its organization 1,619 students have been graduated. Consult Dowst, H. P., 'Radcliffe College' (Boston 1913).

RADEGUNDA, Saint, Frankish queen: b. Thuringia, Germany, 510; d. Poitiers, France, 13 Aug. 587. She was the daughter of the heathen Berthar, king of the Thuringians. After the victory of Clothaire, king of the Franks, over her father, she was carried off, a prisoner. She was eventually converted to Christianity and married to Clothaire (538). After her brother had been murdered by the Franks, she fled from her husband's court and, in 553, took the veil, founded the monastery of Sainte Croix at Poitiers where she resided from then on devoting her life to religious practices and charity. Her life was written by her contemporary and friend, the famous poet, scholar and bishop, Venantius Fortunatus (q.v.). Consult Baring-Gould, S., 'Lives of the Saints' (Vol. IX, Edinburgh 1914); Briand, E., 'Histoire de Sainte Radegonde' (Paris 1898); Migne, J. P., 'Patrologiæ Cursus Completus' (Vol. DXXII, p. 651, Paris 1849).

RADETZKY, ră-dět'skē, **Johann Joseph Wenzel Anton Fritz Karl**, COUNT, Austrian military officer; b. Trebnitz, Bohemia, 2 Nov. 1766; d. Milan, Italy, 5 Jan. 1858. He joined the Austrian army in 1784, served in the campaigns against the Turks in 1788-89, in Holland and Italy, 1793-96, in various parts of

Europe during the later Napoleonic campaigns, became lieutenant field-marshal in 1809 and served with ability at Aspern and Wagram. After the Peace of Schönbrunn he was appointed a member of the state council of war. In the war with France he fought at Kulm and Leipzig in 1815, and in 1831 was made commander of the Austrian troops in Italy. He was created field-marshal in 1836 and in 1848-49 he crushed the revolution in Venice and Milan. He preserved Lombardy to Austria, routed the army of the Piedmontese at Custoza and Novara in 1849, concluded a treaty which assured Austrian supremacy in Italy for the time, and governed the Austrian possessions there until 1857 when he was retired after 72 years' service and after having received 46 European decorations. He trained his soldiers to a very high degree of perfection, and, though a very strict disciplinarian, succeeded in becoming the idol, not only of his troops, but of the people at large. He was kind, frank and scrupulously abstained from playing politics. A very extensive anecdotal literature, some of it in the form of fiction, has developed around his character. There are also many poems and songs about his person and deeds; a collection of songs was published as 'Radetzky lieder' (Aschaffenburg 1851). After his death there were published 'Den Kschriften Militärischen Inhalts und dem Nachlass Radetzky's' (Prague 1858); 'Hondschriftlicher Nachlass Radetzky's' (Stuttgart 1858); 'Briefe des Feldwar Schallös Radetzky an seine Tochter Friederike, 1847-57' (Vienna 1892). Consult Duncker, C. von, 'Das Buch von Vater Radetzky' (Vienna 1891); Gavenda, A. von, and F. de Vuko et Branco, 'Feldmarschall Graf Radetzky' (Prague 1858); Hackländer, F., 'Erinnerungen an die Feldzüge der Oesterreichischen Armee in Italien, 1848-49' (Munich 1852); id., 'Bilder aus dem Soldaten leben im Kriege' (Stuttgart 1887); Heller, F. von, 'Der K. K. RADFORD, William, American naval officer: b. Fincastle, Va., 1 March 1808; d. Washington, D. C., 8 Jan. 1890. He entered the navy in 1825, was promoted lieutenant in 1837, served in the war with Mexico and performed gallant service at Mazatlan. In 1855 he was promoted to the rank of commander and for some years served with the East India squadron. When the Civil War broke out he was assigned to the *Cumberland*, but was not aboard her when she was sunk by the *Merrimac*; although a Southerner by birth, he was a firm supporter of

the Union; he was promoted captain in July 1862 and commodore in April 1863. During the assaults on Fort Fisher, in 1864-65, he commanded the *New Ironsides* and the ironclad portion of Porter's fleet, rendering distinguished services. Later, and until the fall of Richmond, he was in command of the James River division of the North Atlantic squadron. He was commissioned rear-admiral in July 1866, was in charge of the European squadron in 1869 and was afterward on duty in Washington until he was retired in March 1870. After his retirement he was on special duty with the Navy Department in Washington for two years.

RADFORD, Va., city in Montgomery County, on New River, 75 miles southwest of Lynchburg, on the Norfolk and Western Railroad. It dates from 1756 and is chiefly engaged in manufacturing. There are flour mills, iron foundries, brick works and other industries. Pop. 4,202.

RADHANPUR, *rād-han-poor'*, India (1) chief town, of a state in the Palanpur agency of the Bombay presidency, surrounded by a wall which encloses a fortified castle and the residence of the native prince. A fine sort of salt-peter is manufactured and there is some trade in cotton, wheat and grain. Pop. about 11,567. (2) A native state in the northwest corner of Gujerat covering an area of 1,150 square miles. It first came under British protection in 1813. Its native prince, who bears the title Nawab, is a member of the Babi family. The country is a level plain with few trees and no hills whatever. The majority of the inhabitants, over four-fifths, are Hindus. In 1911 the gross revenue was \$87,350. Consult 'Gazetteer of the Bombay Presidency' (Vol. VB, Bombay 1914). Pop. about 65,567.

RADIAN. See **MECHANICS**.

RADIANT STAR, Order of the. See **ORDERS (ROYAL) AND DECORATIONS**.

RADIATA, one of the great divisions of the animal kingdom in the classification of Cuvier, characterized by having the parts of the body arranged around a vertical axis like the spokes around the hub of a wheel. Later, it was shown by Leuckart that the group was unnatural, and it has been discarded for many years. Its chief members are now included in the *Celenterata* and *Echinodermata* (q.v.). As limited by Cuvier it also embraced some of the *Protozoa*, the *Polysoa*, some parasitic worms and a few other forms.

RADIATION. The term radiation is applied to a variety of cases in which energy is propagated through space like rays of light. The case most studied is that of heat. Heat rays are regarded as of the same character as light rays, the two merely differing in wave length or frequency. Writers sometimes speak even of the "color" of a heat ray to indicate its wave length or period. Conversely, every light ray is simultaneously a heat ray. According to Maxwell's theory these rays are all electromagnetic in character, consisting of states of electric and magnetic intensity perpendicular to the ray and propagated through space with the velocity of light.

Heat conduction in a medium proceeds from points of higher to points of lower temperature. If the temperature is constant, there is

no conduction. Radiation is, however, independent of the temperature; for instance, the sun's rays can be concentrated by means of a lens of ice to a focus when the temperature is much higher than that of ice. Furthermore the rays passing through a point do not necessarily proceed in the same direction. They may proceed simultaneously in many different directions. Even the radiations in two opposite directions are quite independent; to specify the radiation completely, the intensity (rate at which energy flows across unit surface perpendicular to the direction of motion) must be known in all directions.

The creation of a heat ray is denoted by the word emission. Since this requires energy, only material particles can emit radiation. When we speak of the surface of a body as radiating heat, we mean merely that it allows part of the rays coming from the interior to pass through.

The radiation emitted by a substance depends on the substance and its physical condition. With the exception of phenomena of luminescence, it is generally assumed that the radiation emitted by a given body depends only on its temperature and is otherwise independent of the presence or absence of other bodies or fields of radiation.

Heat rays are destroyed by absorption. They are then converted into other forms of energy. This can be accomplished only by material particles. Rays of different frequency may be absorbed very unequally, but it is assumed that the fractional part of the rays of each frequency absorbed in penetrating a given distance through a given medium is independent of the intensity of the radiation.

A transparent, or diathermanous body is one through which the rays pass practically unchanged. If the rays pass freely but are deflected, or scattered, the body is turbid. If the surface is smooth, the rays may be regularly reflected as by a mirror. If the surface is rough, the rays may still be practically all reflected, but irregularly in all directions. The body is then white. A black body is one that absorbs all the incident radiation.

Normal, or Black, Radiation.—The simplest type of radiation is that which occurs in an enclosure at constant temperature. The total radiation from a given body under these conditions is called normal radiation.

Consider a number of bodies in an enclosure with perfectly reflecting walls. These bodies exchange heat until they settle to a uniform temperature. They then continue to exchange heat by radiation but each receives just as much as it gives out (Prevost's principle of exchanges). The composition of the resulting radiation is independent of the nature of the bodies present. For, if it were not so, the introduction of a new body would change the composition of the radiation in the enclosure and, since the emissive power of each body is a function of its temperature only, the resulting changes in the amount of radiation absorbed would cause changes of temperature in contradiction to the second law of thermodynamics.

For a region in temperature equilibrium, according to Kirchhoff's law, a body not only receives the same total energy it gives out; but it absorbs precisely the same amount of each wave length that it emits; for the radiation

received and given out are both normal radiation. If any radiation is absorbed it must be replaced by precisely the same radiation in emission. It follows, for example, that a body which does not emit a particular wave length cannot absorb radiation of that wave length and conversely.

Since a black body merely emits and does not transmit or reflect radiation, and since emission depends merely on temperature, the radiation from a black body is the same whether it is in an enclosure at constant temperature or not. Hence the radiation given out by a black body is always normal. For this reason normal radiation is often called black body radiation.

Composition of Black Body Radiation.—Consider the radiation in an enclosure where the absolute temperature is T . We have seen that the character of this radiation is a function of the temperature only. If then $u(\lambda) d\lambda$ is the amount of heat energy per unit volume which exists in wave trains of which the wave lengths lie between λ and $\lambda + d\lambda$, the quantity $u(\lambda)$ will be a function of λ and T only. The determination of this function is one of the most important problems in the theory of radiation.

The first formula for $u(\lambda)$ was obtained by Jeans and Lord Rayleigh. Jeans' method was to start from the well-known result in statistical mechanics, that, in a dynamical system of a large number of degrees of freedom the energy on the average is distributed equally among the various degrees of freedom, so that each has an amount of energy $\frac{1}{2} RT$, where R is an absolute constant. By counting the number of ways in which wave lengths between λ and $\lambda + d\lambda$ can occur in stationary vibrations in a fixed enclosure and giving to each two degrees of freedom, corresponding to the two plans of polarization, Jeans found that

$$u(\lambda) = \frac{8\pi RT}{\lambda^4}.$$

This is known as Rayleigh's law of radiation. For large values of λ it represents the facts fairly well. But for small values of λ it disagrees entirely with experiment and leads to the rather questionable conclusion that the total energy per unit volume

$$\int_0^\infty u(\lambda) d\lambda$$

is infinite.

A formula that does not have these defects and that seems entirely in accord with experimental values was first obtained by Planck. His result is

$$u(\lambda) = \frac{8\pi ch}{\lambda^5 \left(e^{\frac{ch}{\lambda T}} - 1 \right)},$$

where c is the velocity of light, h and R constants.

To obtain this formula, Planck assumed that molecular systems do not emit radiant energy continuously but in chunks or "quanta." Radiation of frequency ν is only emitted in multiples of $h\nu$, where h is a universal constant. The simplest proof of the formula is a modification of that given by Jeans. Consider a system of stationary electromagnetic waves in a rectangular enclosure.

The number of ways per unit volume in which such waves with frequency between ν and $\nu + d\nu$ can be set up is

$$\frac{8\pi\nu^2 d\nu}{c^3},$$

as in Jeans' proof. If now energy occurs only in multiples of $\epsilon = h\nu$, and is distributed as is Gibbs's canonical ensemble, the average energy for a wave of particular frequency is

$$\frac{\sum \epsilon e^{-\frac{\epsilon}{RT}}}{\sum e^{-\frac{\epsilon}{RT}}} = \frac{0 + \epsilon e^{-\frac{\epsilon}{RT}} + 2\epsilon e^{-\frac{2\epsilon}{RT}} + \dots}{1 + e^{-\frac{\epsilon}{RT}} + e^{-\frac{2\epsilon}{RT}} + \dots} = \frac{\epsilon}{e^{\frac{\epsilon}{RT}} - 1}.$$

Hence

$$u\nu d\nu = \frac{8\pi\nu^2}{c^3} \left(\frac{\epsilon}{e^{\frac{\epsilon}{RT}} - 1} \right) = \frac{8\pi h^3 \nu^3 d\nu}{c^3 \left(e^{\frac{h\nu}{RT}} - 1 \right)}.$$

By using the relations

$$\nu = \frac{c}{\lambda}, \quad u\lambda d\lambda = u\nu d\nu,$$

this gives the formula above.

This "quantum theory" that radiant energy is emitted only in multiples of $h\nu$ has been the subject of very general discussion. There are some who still doubt its validity. Poincare has shown, however, that any law of radiation in which the total energy in unit volume is finite requires discontinuities similar to those involved in the hypothesis of quanta. N. Bohr has given a suggestion as to the physical significance of quanta. He assumes that atoms consist of positive nuclei with negative electrons revolving like planets around them and that there is a series of stable orbits in which each electron can revolve continuously. If disturbed it will either return to its orbit and give out no energy or it will change to another orbit and, in so doing, give off energy equal to the difference of its energies in the two orbits. In this way he calculated the spectrum of hydrogen, the calculation as given by Millikan, agreeing with measurement to less than one part in a thousand. This and other equally striking results indicate that the quantum hypothesis has a substantial basis of truth.

Deductions from Planck's Law.—In a constant temperature enclosure, radiant energy travels with the velocity of light, spreading out equally in all directions. The rate at which it crosses a given area in a given direction is then proportional to the density of radiation in the enclosure. If $E(\lambda) d\lambda$ is the portion crossing unit area in unit time carried by wave trains with wave length between λ and $\lambda + d\lambda$, by Planck's law

$$E(\lambda) = \frac{c_1}{\lambda^5 \left(e^{\frac{c_2}{\lambda T}} - 1 \right)},$$

where c_1 and c_2 are constants. This is also the radiation emitted by a black body at temperature T whether it is in a region of constant temperature or not.

The total radiation of all wave lengths

across unit area of the surface of a black body is

$$\int E(\lambda) d\lambda = \int_0^\infty \frac{a}{\lambda^5} \left(\frac{a}{e^{\frac{a}{\lambda T}} - 1} \right) d\lambda.$$

Letting $\lambda T = x$, this becomes

$$\int_0^\infty E(\lambda) d\lambda = T^4 \int_0^\infty \frac{c_1}{x^5} \left(\frac{c_2}{e^{\frac{a}{x}} - 1} \right) dx = a T^4,$$

where a is constant. This expresses Stefan's law that the total radiation from a black body is proportional to the fourth power of the absolute temperature.

The value λ_m for which $E\lambda$ is a maximum must satisfy the equation

$$\frac{dE}{d\lambda} = 0,$$

which reduces to

$$5\lambda T \left(\frac{a}{e^{\frac{a}{\lambda T}} - 1} \right) = a.$$

Since the left side of this equation is a function of λT ,

$$\lambda_m T = k,$$

where k is constant. This expresses Wien's law that the wave length corresponding to maximum energy is inversely proportional to the temperature.

Both Stefan's law and Wien's law can be proved directly by thermodynamics. They, therefore, further corroborate Planck's law.

A practical application of Wien's law occurs in the problem of the luminous efficiency of a lamp. At ordinary temperatures λ_m is much larger than the wave lengths of visible radiation. Practically all the energy is radiated as heat. As the temperature increases λ_m decreases and the proportion of visible radiation thus increases. Hence the efficiency of a lamp is increased by increasing as far as practicable the temperature of the incandescent element.

Optical Pyrometry.—The laws of black body radiation indicate methods of determining temperature. For example, since the total radiation of a black body is proportional to the fourth power of its absolute temperature, the temperature of a radiating black body can be calculated from the observed intensity of radiation, allowance being made for the size of the body and its distance from the point of observation.

Again, if we determine by observation the value of λ which makes $E(\lambda)$ a maximum, Wien's law

$$\lambda_m T = k,$$

enables us to determine T . In this way the temperature of the sun has been found to be about 5500° C.

By measuring the ratio of two values of $E(\lambda)$

$$\frac{E(\lambda)_2}{E(\lambda)_1} = \frac{\lambda_1^5 \left(\frac{a}{e^{\frac{a}{\lambda_1 T}} - 1} \right)}{\lambda_2^5 \left(\frac{a}{e^{\frac{a}{\lambda_2 T}} - 1} \right)},$$

since C_2 is a known constant, we can calculate T . This is essentially the basis of the practical form of pyrometer known as the Warner pyrometer.

These optical methods are all subject to error when the radiating body is not a black

body. The value of these methods is that they can be used for temperatures much higher than can be measured by other means and by using a black body at the same temperature the error can be determined. The most widely used optical pyrometer is one in which the carbon filament of a lamp is seen projected on the hot body whose temperature is to be measured. The current through the lamp is increased until the filament is no longer visible and the temperature is then inferred from the observed value of the electric current. The slight differences of color between the filament and background are eliminated by using a red glass.

Selective Emission, Reflection and Transmission.—A substance placed in an environment not in temperature equilibrium usually gives out a radiation that is not the normal radiation for its temperature but contains a larger percentage of certain wave lengths than normal radiation and a smaller percentage of others. Such a substance is said to exhibit selective action.

The total radiation coming from the body is partly emitted, partly reflected and partly transmitted through the body. The selective action may then be a case of selective emission, selective reflection or selective transmission. If one of these occurs, one or both the others must occur. For in temperature equilibrium the total radiation is normal, and any deficiency in emission must be made up by transmission or reflection. Now these qualities depending only on the nature of the body and its temperature persist when there is not temperature equilibrium with proper allowance of course for the fact that the incident radiation is not normal.

The following are special cases of particular interest:

(a) *Bodies Which Do Not Reflect Perceptibly.*—Such bodies do not transmit (i.e., they absorb) those wave lengths which they emit in excess. The transmitted and emitted radiations are in a sense complementary. This is the case, for example, with gases. They do not reflect perceptibly and they absorb in excess those wave lengths which they emit.

(b) *Bodies Which Are Opaque, i.e., Do Not Transmit.*—Such bodies emit radiation complementary to that which they reflect. For example, a polished metal plate is opaque and reflects nearly all the light falling on it. Therefore, it does not emit perceptibly. For this reason the walls of a thermos bottle are silvered.

(c) *Bodies Which Do Not Emit Perceptibly.*—Such bodies reflect best those wave lengths they do not transmit. Thus many bodies have what is called surface color. They appear one color by reflected light, another by transmitted light.

(d) *Opaque Bodies Which Do Not Reflect.*—These are black bodies. They emit normal radiation.

Fluorescence.—Many substances when illuminated by monochromatic light have the property of emitting light of a different color or frequency. This phenomenon is called fluorescence. From his investigations, Stokes concluded that the fluorescent light is invariably of lower frequency than the exciting light. This is sometimes called Stokes' law. Later observers have proved that it is not always true.

If the fluorescent emission lasts for some time after the exciting radiation has been cut off the phenomenon is called phosphorescence. There is no sharp line of demarcation between fluorescence and phosphorescence, as the duration referred to may take almost any time from zero upward. In liquids and gases this duration has always been found too small to measure. Only in solids does phosphorescence properly occur.

It is probable that phosphorescence is always accompanied by the liberation of electrons. The exciting light causes the emission of electrons from some constituent of the material and the fluorescent light arises from the recombination of these emitted electrons. The duration of luminescence is determined by the resistance to this recombination and is consequently greater in solids than in liquids or gases. This is further confirmed by the fact that fluorescence is strongly affected by changes in the physical condition of the bodies exhibiting it. Thus, some substances are only fluorescent when dissolved in non-fluorescent liquids, while others are fluorescent in the solid state but not when dissolved.

Of particular interest is the work of R. W. Wood on the fluorescence exhibited by the vapor of iodine. When stimulated by monochromatic light, the fluorescent spectrum is not continuous but consists of a series of fine lines whose frequencies are approximately equidistant with the line of the incident radiation forming one of the series. The positions of these lines change in a remarkable way when the frequency of the exciting light is altered. The absorption spectrum of iodine has seven very fine lines within the width of the green line of mercury. When the green mercury line is used for excitation it is found that a large number of the fluorescent lines are made up of fine lines having a structure similar to these seven absorption lines. This line spectrum has the further property of being converted into a band spectrum by an admixture of certain inert gases like helium.

H. B. PHILLIPS,

Massachusetts Institute of Technology, Cambridge, Mass.

RADIATION OF HEAT. See HEAT.

RADIATOR. See INTERNAL COMBUSTION ENGINE.

RADICAL, or RADICLE, in chemistry (and particularly in organic chemistry), a name given to certain molecular groups whose constituent atoms possess such relations and affinities that the groups themselves persist and maintain their integrity, even when the compounds in which they occur undergo profound chemical change. The following example will illustrate the nature of a radical more clearly: Ordinary alcohol (ethyl alcohol), when free from water, has the chemical formula C_2H_5O . If this be saturated with hydrochloric acid gas in the presence of chloride of zinc, a compound having the formula C_2H_5Cl is formed; and by treating the alcohol with iodine under proper conditions, an analogous compound having the formula C_2H_5I is obtained. When this last substance is heated with water and metallic zinc, we obtain the hydrocarbon gas ethane, C_2H_6 . These reactions, and others of a similar nature, suggest that the molecular group C_2H_5 persists through all of these changes; and this

hypothesis is found to be justified in every way. The group C_2H_5 is, therefore, a "radical," and to it the name "ethyl" has been given. The gas ethane, C_2H_6 , is the hydride of ethyl, according to this view, and its formula may be written C_2H_5H . Similarly, C_2H_5Cl and C_2H_5I are called ethyl chloride and ethyl iodide, respectively. Ethyl alcohol, in the same way, is regarded as the hydrate of the radical ethyl, and its formula is written $C_2H_5.OH$. Ethyl is thus seen to be a monovalent radical with a high degree of stability, behaving, in its chemical relations, very much like the alkali metals, potassium and sodium. Many compounds are known in which two or more molecules of ethyl occur, with their combined valencies satisfying a single divalent atom or radical. Ordinary ether, for example, is the oxide of ethyl, its formula being $(C_2H_5)_2O$. The analogy of this substance with the oxide of potassium, K_2O , is complete.

If the persistence of a radical were absolute, so that we could never destroy the radical by any chemical or physical means, we obviously could not distinguish it from an element; and it is possible that some of the bodies that we now recognize as elements are merely radicals of extraordinary persistence, which we may some day succeed in breaking up into their constituents. This is pure speculation, however, and until we know more about the ultimate constitution of matter, we are to regard a "radical" merely as a convenient conception, which enables us to simplify chemical formulae, and to form a clear general view of the analogies and chemical relations that subsist among various chemical compounds. Radicals may be classed as "acid" or "basic," according as they have an acid or a basic character. Thus the radical SO_4 , which occurs in sulphuric acid and in the sulphates, and which is called "sulphion," is an acid radical, while ethyl, C_2H_5 , is basic.

Among the simpler inorganic radicals that are of frequent occurrence, the following are monovalent: Hydroxyl (OH), the "nitro" group (NO_2), the "nitroso" group (NO), the "amido" group (NH_2) and cyanogen (CN). The following are divalent: Sulphonyl (SO_2), sulphuryl (SO_2), the "imido" group (NH) and the "thionyl" group (SO). In organic chemistry many radicals are recognized. The commoner basic radicals of the fatty series may be regarded as derived from the saturated hydrocarbons (or paraffins) by the removal of one or more atoms of hydrogen. Thus we have the following series, which are derived in the manner described, the radicals in each column being obtained from the paraffin at the head of that column by the removal of hydrogen atoms:

CH_4	C_2H_6	C_3H_8	C_4H_{10}	C_5H_{12}
Methane	Ethane	Propane	Butane	Pentane
CH_3	C_2H_5	C_3H_7	C_4H_9	C_5H_{11}
Methyl	Ethyl	Propyl	Butyl	Pentyl
CH_2	C_2H_4	C_3H_6	C_4H_8	C_5H_{10}
Methylene	Ethylene	Propylene	Butylene	Pentylene
CH	C_2H_3	C_3H_5	C_4H_7	C_5H_9
Methenyl	Ethenyl	Propenyl	Butenyl	Pentenyl
C	C_2H_2	C_3H_4	C_4H_6	C_5H_8
(Carbon)	Ethine	Propine	Butine	Pentine

The names here assigned to the radicals are due to Hofmann, and the system in accordance with which they are formed will be sufficiently evident, without further explanation. Hofmann's names are now commonly adopted, but some of the foregoing radicals are still known by other names also. Thus Hofmann's

"ethenyl" is often called "vinyl"; and, similarly, his "propenyl," "butenyl," "ethine," "propine," and "butine" are respectively known as "glyceryl," "crotyl," "acetylene," "allylene" and "crotonylene."

The radicals tabulated above and which are of constant occurrence in organic chemistry contain only hydrogen and oxygen. Many organic radicals are known, however, which contain other elements also. The first oxygen-bearing group to be recognized as a radical was "benzoyl," C_6H_5CO , which occurs in benzoic acid, and in many other compounds that are related to the oil of bitter almonds. This radical was recognized by Liebig and Wöhler, in 1832. Many such radicals are now recognized, especially in the organic acids and their derivatives. As an example, "acetyl" may be cited. This has the composition C_2H_3O , and acetic acid, $C_2H_4O.OH$, is its hydrate.

Many of the radicals are not capable of independent existence, and hence cannot be isolated. Others may be obtained in the free state, or in the form of a compound in which two similar radical groups are united to each other. When methyl iodide is heated with metallic zinc the iodine is taken up by the zinc, and the methyl radical, CH_3 , is liberated. It is not obtained in the form of methyl, however, for at the moment of its liberation two of the radicals combine to form a molecule of ethane, C_2H_6 . Ethane, therefore, may be regarded as "di-methyl," having the formula CH_3-CH_3 , or as "ethyl hydride," having the formula $C_2H_5.H$. It is convenient to regard it from one of these points of view for some purposes, and from the other for other purposes. A radical of the series tabulated herewith can exist in the free state, save for a slight change in its internal linkage, provided its valency is an even number, and the free bonds belong to adjacent carbon atoms. Ethylene, for example, has the formula C_2H_4 . When it exists as a radical, in combination with other atoms, it is divalent, and has the structure

$-CH_2-$
|
|; the two carbon atoms being connected
 $-CH_2-$
by one internal bond, while each carbon atom also has one bond which is satisfied by the external atoms with which the radical is combined. When the ethylene exists as a free hydrocarbon, the two free bonds shown in the foregoing rational formula satisfy each other, and the constitution of free ethylene, therefore,
 CH_2
is ||
 CH_2

The idea of a compound radical is due to Lavoisier; and the conception, although its validity was earnestly disputed for some years, has been of great importance in the development of chemistry. The definition of a radical, as given by Liebig in 1838 in his discussion of cyanogen, holds good at the present day. He said: "We call cyanogen a radical because (1) it is the invariable constituent in a series of compounds; (2) because it can be replaced in these compounds by other simple bodies; (3) because in its compounds with a simple body the latter can be replaced by equivalents of other simple bodies." At least two of these three characteristics must be fulfilled by a group of atoms, before that group can be regarded as a "radical."

Consult Hjelt, 'General Organic Chemistry'; Meyer, 'Modern Theories of Chemistry.'

ALLAN D. RISTEEN.

RADICAL, the name adopted by a large section of the Liberal party in Britain, which desires to have all abuses in the government completely rooted out, and a larger portion of the democratic spirit infused into the constitution. The immediate aim of Radicals at different times has necessarily varied considerably; and though the party is now identified almost exclusively with political reform, the Radicals of the past achieved their greatest success in compelling attention to important economic changes tending to improve the condition of the laboring population. The term is applied in general usage to persons of extreme views in connection with so-called political and social reforms.

RADIGUET, Maximilien René, French explorer: b. Landerneau, Finisterre, 17 Feb. 1816; d. 1892. He was educated in the School of Fine Arts at Paris and in 1838 became secretary to Admiral Charles Baudin and Count de Las Casas, on a mission that had been sent to Haiti to negotiate with the government of that country for the payment of an indemnity to the descendants of the French citizens that had been murdered during the troubles of 1798-1803. His influence was of great value in bringing the negotiations to a speedy conclusion, several times preventing the impatient admiral from bombarding Cape Haytien. He was afterward secretary to Admiral Du Petit-Thouars, 1841-45, and traveled through South America and the Marquesas Islands, and afterward devoted himself to literary labors. Among other works he has published 'Album des Voyages de la Reine Blanche' (3 vols.); 'Souvenirs de l'Amérique Espagnole: Chili, Pérou, Brésil' (Paris 1856; revised ed. 1874); 'Etudes de mœurs sur l'Amérique du Nord' (Paris 1857); 'Les Derniers Sauvages, Souvenirs de l'Occupation Française aux Îles Marquises' (Paris 1861); 'A travers la Bretagne' (Paris 1865).

RADIOACTIVITY. The discovery that uranium possesses the property of spontaneously and continuously emitting penetrating rays, capable of passing through bodies opaque to ordinary light, was made by Becquerel in 1896. Since that time our knowledge of the subject of radioactivity has increased with great rapidity and a very large mass of experimental facts has now been accumulated. Only a very brief account of the remarkable properties possessed by the radioactive bodies is possible in this short article.

Shortly after the discovery of this property in uranium, Mme. Curie and Schmidt independently found that the element thorium, which is used in the manufacture of Welsbach mantles, was also radioactive and to about the same degree as uranium. The latter substance is the chief constituent of the mineral pitchblende and in an examination of the radioactive properties of this mineral, Mme. Curie was led to the conclusion that other and more radioactive substance must be present in it. By an admirable piece of chemical research Mme. and P. Curie succeeded in separating from it two new very active substances which were called radium and polonium. The substance radium was well named as, in the pure state, it gives out radiations about 4,000,000 times as intense

as uranium. Polonium has not yet been chemically isolated. It differs from radium in losing its activity with time. Several years after separation the activity has diminished gradually to an insignificantly small fraction of its original value.

In addition to these bodies, Debierne and Giesel independently discovered another very active substance called actinium, while Hofmann found that lead separated from pitchblende was active and called the radioactive substance present in it "radio-lead." Somewhat later a radioactive substance called ionium was isolated from uranium minerals by Boltwood. With the exception of radium, none of these bodies have been chemically isolated.

The radiations from these substances are invisible to the eye, but possess the properties of acting on a photographic plate and discharging an electrified body. The rays from a very active substance like radium cause many phosphorescent substances to become luminous. An ordinary X-ray screen, crystalline zinc sulphide and the minerals willemite and kunzite glow brightly when exposed to radium rays. A photographic plate is rapidly affected by bringing near a few milligrams of radium bromide, and an electroscope quickly loses its charge.

The radiations from the active bodies have been shown to consist of three distinct kinds, known as α , β , and γ rays. Unlike ordinary light-waves, the α and β rays consist of a flight of charged particles projected with enormous velocity. They differ from ordinary light inasmuch as a pencil of these rays is deflected by a magnetic and electric field. These properties of the radiations have allowed us to determine the size of the particle and its velocity of projection. Rutherford found that the α rays consisted of atoms of matter carrying a positive charge and moving with a velocity of about 20,000 miles a second. The α rays are readily stopped by matter, being absorbed by a few centimeters of air and by a sheet of ordinary note paper. The β particles, on the other hand,

	MASS	VELOCITY	ENERGY
α	○	—	⊗
β	•	—	•

[9]

FIG. 1.

are far more penetrating and pass through several millimeters of aluminum or iron. The β particles differ from the α particles in carrying a negative charge and in their much greater velocity of projection. Some of them move with a velocity of over 170,000 miles per second—a speed very nearly equal to that of light. The β particle has been found by Becquerel and Kaufmann to be identical with the cathode particle produced by a discharge in a vacuum tube. It has the smallest size of any body known to science, for its mass is only about 1/1700 of that of the atom of hydrogen. It was shown in a series of experiments conducted by Rutherford that the α particles consist of

atoms of helium bearing a positive charge. The relative sizes and velocities of the α and β particles are diagrammatically shown in Fig. 1. The relative energies of motion of the particles are also shown.

The γ rays are of an extraordinary penetrating character, readily passing through several inches of iron or lead and several feet of water. They are not deflected by a magnetic or electric field and are a type of very penetrating X-rays. The latter consist of pulses in the ether, akin in some respects to the very short waves of ultra-violet light.

If a magnetic field is applied to a pencil of

FIG. 2.

rays from radium, the rays are sorted out into the three kinds. This is shown in Fig. 2, where the magnetic field is applied at right angles to the plane of the paper. The α particles are bent to the left, the β to the right, while the γ rays proceed in a straight line without deviation. Compared with the β rays, the amount of bending of the α rays is much exaggerated in the figure, for a very strong magnetic field is required to appreciably deflect the latter. The β rays consist of particles projected with different velocities, so that some are more easily bent by a magnetic field than others. This is shown in the figure.

The expulsion of α and β particles from the atoms of the radioactive bodies appears to result from an explosion in some of the atoms of these substances. About thirty-six thousand million of these α particles are expelled from one gram of radium element every second; and yet the number of atoms in a gram of radium is so enormous that this rate of expulsion can continue for several years without any sensible alteration or diminution of the quantity of radium.

The most important property of the α , β , and γ rays is their power of discharging an electrified body and this property has been utilized as a means of quantitative measurements of the radiations. The ordinary gold leaf electroscope, such as is shown in Fig. 3, can be used to measure radiations of extremely small intensity. A simple gold leaf is attached to a metal rod passing through an insulating cork of sulphur or ebonite. On giving a charge to

this rod, the gold leaf diverges and, under ordinary conditions, the gold leaf collapses very slowly. If, however, a radioactive substance is brought near it, the charge on the system is dissipated and the gold leaf rapidly collapses.

The radiations produce a large number of positively and negatively electrified particles or ions, as they are called from the neutral gas. If the electroscope is charged positively, for

FIG. 3.

example, the negative ions are drawn into it and dissipate its charge. Under suitable conditions, the rate of movement of the gold leaf is a measure of the intensity of the radiations. A modified form of gold leaf electroscope is capable of detecting the presence of an extraordinarily small quantity of radioactive matter. One millionth of a gram of radium bromide causes the gold leaf to collapse in a few seconds, and, with care, the effect of one million millionth of a gram can be accurately determined. As a means of detection of radioactive matter in small quantity, the electroscope far transcends in delicacy even the spectroscopic. The ordinary quadrant electrometer is also a very convenient instrument for measuring the small ionization produced by the radiations in the air or other gas through which they pass.

In addition to their power of giving out the three kinds of rays, radium, thorium and actinium also possess another very remarkable property. Each of these substances continuously gives off into the air a minute quantity of gas, which is itself radioactive. This "emanation," first discovered by Rutherford in thorium, gradually diffuses from the radioactive body into the surrounding gas and can be carried away with a current of air. The "emanations," however, only keep their power of radiating for a short time.

The activity of the emanation decreases in a geometrical progression with the time; the emanation from thorium loses half of its activity in about one minute; from radium in about four days; and from actinium in about four seconds.

These emanations have been found to possess all the properties of radioactive gases

mixed in minute quantity with the air. The emanations of thorium and radium behave like heavy gases and are chemically inert like the recently discovered members of the argon-helium family. The emanations can be removed from the air by the action of extreme cold. The emanation of thorium condenses at -120°C , and that from radium at -150°C . This property of condensation of the emanation from a very active substance like radium can readily be followed by the eye. The emanation released from radium is stored with air in a small reservoir (Fig. 4). It is slowly passed through a U tube of glass, filled with fragments of the phosphorescent mineral willemite. The tube is immersed in a vessel filled with liquid air. The emanation condenses in the tube immediately below the level of the liquid air and the radiations from the condensed emanation cause the willemite to become luminous. On removal of the tube and closing the ends, the emanation, after some time, is again volatilized and distributes itself throughout the tube, causing a uniform luminosity throughout it. With a large quantity of radium emanation, such an experiment is extremely striking.

Ramsay and Soddy succeeded in isolating the emanation of radium. This gas is brilliantly luminous and rapidly blackens the tube containing it. The emanation has a definite spectrum of bright lines, similar in general character to that observed for the inert gases argon or helium.

Curie and Laborde first observed the striking fact that radium kept itself continuously at a temperature several degrees higher than the

FIG. 4.

surrounding air. The radium is continuously emitting heat at the rate of 132 gram calories per hour per gram of radium in equilibrium with its short-lived products; that is, it would heat its own weight of water through more than 100°C . in one hour. Rutherford and Barnes showed that the greater part of the heating effect of radium was not due directly to the radium itself, but to the emanation continuously produced from it. This emanation was separated from the radium, and condensed in a small glass tube immersed in liquid air. The heating effect of the minute quantity of emanation thus obtained was found to be three quarters of that originally possessed by the radium. Compared with its weight, the radium emanation emits a quantity of energy more than a million times greater than that released in the most violent chemical reaction. The heating

effect of the emanation is not, however, permanent, but dies away with the time at the same rate as it loses its activity; that is, it falls to half value in about four days.

If a cubic centimeter of the emanation were collected in a glass tube, it would probably give off sufficient heat to melt down the walls of the tube. It can readily be deduced that one pound weight of the emanation, after its separation from radium, would emit energy at the rate of 10,000 horse power and, during the time that its activity lasts, would emit an amount of energy corresponding to 60,000 horse-power days. The heating effects of radium have been found to be directly due to the expulsion of α particles from its mass. Each of these particles is projected with such a great velocity that it has considerable energy of motion, which is transformed into heat when it strikes a body. These α particles are easily stopped by matter and, in a mass of radium, most of the α particles projected throughout its volume are not able to escape, but are stopped by the radium itself. Radium is thus heated by the unceasing and vigorous self-bombardment by the α particles shot out from its own mass. The heating effect of the emanation in a similar way, is due to the energy of motion possessed by the α particles expelled from it.

The emanations all show another very striking property. If the emanation is drawn through a tube, the surface of the tube becomes coated with an invisible active deposit. This deposit can be dissolved in acids, and after evaporation of the solvent, remains behind on the dish. After removal of the emanation, the deposit gradually loses its activity but at a different rate from the emanation itself. This "excited" or "induced" activity, as it is termed, is due to radioactive matter which arises from the decomposition of the emanation. The excited activity of thorium falls to half value in 11 hours, that of radium in about 30 minutes, and that of actinium in 36 minutes.

Considerable light was thrown on radioactive phenomena by some experiments of Rutherford and Soddy that will now be considered. It was found that an intensely active substance called thorium X could be separated by a single chemical process from thorium. If some thorium nitrate is dissolved in water and ammonia added, the thorium is precipitated. If the ammonia solution is then evaporated and ignited, a very active residue is obtained, several thousand times more active, weight for weight, than thorium itself. The thorium itself is at the same time deprived of more than half of its original activity. A very interesting result is then observed. The activity of this residue thorium X is found not to be permanent but to decay according to a geometrical progression with the time, falling to half value in four days. At the end of a month, the activity is less than 1 per cent of the initial value. At the same time, the precipitated thorium regains its lost activity, such that the sum of the activity of the thorium and thorium X together is always the same, and equal to that of the original thorium before chemical treatment. At the end of a month's interval, the thorium has nearly recovered its old value, and a new quantity of thorium X can then be obtained by the same chemical operation. This process can be continued indefinitely provided sufficient in-

terval is allowed to elapse between each precipitation for the thorium to regain its activity. These results are very simply and fully explained on the following hypothesis. A small fraction of the thorium atoms every second becomes unstable and breaks up with explosive violence, an α particle being projected during the process. After the expulsion of an α particle, the residue of the thorium atom is lighter than before and becomes the atom of the new substance, thorium X. This substance is again unstable and breaks up with the expulsion of α particles, half of the matter breaking up in four days. In ordinary thorium, there are thus two opposing processes at work. The substance thorium X is produced at a constant rate by the disintegration of some of the thorium atoms, and at the same time this thorium X breaks up and changes into another substance. A steady state will obviously be reached when the number of atoms of thorium X, which are produced per second, is equal to the number of atoms of thorium X which break up per second. The constant radioactivity of thorium may thus be likened to the constant population of a country, where the number of births is equal to the number of deaths.

It has been found experimentally that the property possessed by thorium of giving off an emanation belongs not directly to the thorium but to its product, thorium X. The amount of the emanation is always proportional to the amount of thorium X present, and thorium freed from thorium X does not emit any emanation. This shows that thorium X is the parent of the emanation. According to the disintegration theory, advanced by Rutherford and Soddy, the atom of the emanation arises as a result of the expulsion of a particle from the atom of thorium X. In a similar way it has been shown that the emanation is transformed into the active deposit which has been found to consist of a number of distinct substances, four in all, which are successive products formed from the thorium emanation. These constituents can be separated from one another by electrolysis, or by utilizing the differences in their volatility when subjected to heat.

The process of analysis which has been applied to thorium has been applied with equal success to uranium, radium and actinium. Sir William Crookes found that uranium has a product called uranium X, which is half transformed in 22 days and gives out only β and γ rays. The product actinium X was discovered by Godlewski. The production of a series of disintegration products amounting to seven in all has been observed in the case of actinium. It is impossible in this short article to discuss in detail the experiments by which the presence and properties of these series of products, resulting from the transformation of the radioelements, have been determined.

It will be seen that seven distinct transformation products have been found in radium. The active deposit of rapid change arising from the emanation consists of three substances, called radium A, B and C, which are half transformed in 3, 27 and 19 minutes, respectively. After these products have undergone transformation, a residue of very slight activity remains. The properties of this residue were examined by Rutherford, who showed that it breaks up through three successive stages, called radium

D, E and F. The substance radium D gives out soft beta rays, and is transformed very slowly—about half value in 16 years. The examination of this residue brought to light the very important fact that polonium is a product of the disintegration of radium. The product radium F is identical with polonium, for their chemical and physical properties are the same, and both lose their activity at the same rate. It has also been shown that radium D is the primary substance, which causes the activity observed in the radio-lead of Hofmann. The active substances present in polonium, and radio-lead are thus proved to be members of the radium family.

The products obtained from the radio-elements all possess some distinctive physical and chemical properties, which distinguish them not only from other products but also from the parent element. For example, radium—a solid substance with chemical properties closely allied to barium—is transformed into a gaseous substance, the radium emanation. The emanation in turn is transformed into a solid. Each of these products must be considered a distinct chemical substance. They differ from the ordinary chemical elements in the fact that they are unstable and undergo transformation into other or new kinds of matter. On account of their very limited life, these products exist in very minute quantity, and it is only in the case of a comparatively slowly changing product like the radium emanation that a sufficient amount can be obtained to measure. There is no doubt, however, that both radium D and F will ultimately be obtained in sufficient quantity to obtain their spectrum and chemical constants.

In the radio-elements, we are witnessing the transformation of matter through a series of successive stages. The products represent the halting places where the matter is able to exist a short time before it breaks down into new forms. This process of transformation is spontaneous and, as far as observation has at present gone, cannot be hastened or retarded by any physical or chemical agencies.

Since the radio-elements are steadily being transformed, the original matter must slowly disappear and be changed into other kinds. It can be calculated with some confidence that radium will be half transformed in about 1,690 years. A feebly active substance like uranium will take several thousand million years to be half transformed. The radio-elements apparently only differ from their products in their length of life; that is, in the stability of the atoms composing them.

A mass of radium left by itself would, in the course of 20,000 years, be almost completely transformed. Since the age of the minerals in which radium is found is known to be much older than this, it is necessary to suppose that radium is constantly produced from some other substance. The ultimate parent of radium is the heavy element uranium, with which it is always found associated. Such a view was strongly confirmed by investigations of Boltwood, Strutt and McCoy. Boltwood found that the amount of radium in different radioactive minerals, obtained from different parts of the world, is always proportional to their content of uranium. Such a relation indicates that radium is derived from uranium. If this is the case, a quantity of uranium, initially freed from

radium, should in the course of time produce some radium. Such a growth of radium from uranium has actually been recorded in some experiments by Soddy and Whetham. The rate of production observed is, however, much slower than is to be expected if uranium passes directly into radium. It has been shown by Boltwood that an intermediate substance, ionium, is first produced and that this in turn changes into radium. The evidence is thus very strong that one element uranium produces another element ionium, which then produces radium. Each of these radioactive products is quite distinct in physical and chemical properties from its parent.

The radioactive minerals must be considered as nature's laboratory in which all the products of transformation of the radioactive substances will be found. Rutherford and Soddy early suggested that the rare gas helium, which is always found associated with the radioactive minerals was a transformation product of the radio-elements. This prediction was verified by some very striking experiments made by Ramsay and Soddy. They removed the emanation from a quantity of radium and collected it in a tube. A discharge was passed through this tube and the light examined by a spectroscope. After standing several hours the spectrum of helium was observed, showing that this gas had been produced during the transformation of the emanation. Here again we have an example of the production of one element helium from another.

It has also been observed that an element having chemical properties identical with those of lead is found in uranium minerals. This element is known as uranio-lead and is supposed to be the final disintegration product of the uranium. Its atomic weight has been found to be approximately 206 and in this respect it differs from ordinary lead which has an atomic weight of over 207.

The helium found in radioactive minerals is thus a decomposition product of radium and also of the other radioactive substances present in it. It seems likely that we shall be able to form a rough estimate of the age of the radioactive minerals by measuring the amount of helium and lead found in them, since for a given amount of radioactive matter present, the amount of helium and lead will be greater the longer the mineral has been formed.

Although radium is found in the highest proportion in the mineral pitchblende and in all other uranium minerals, it is also found distributed in minute quantity over the whole surface of the earth. This has been clearly brought out by the long series of investigations made by Elster and Geitel of the radioactivity of different soils and of the atmosphere. J. J. Thomson, Himstedt, Strutt and many others have found that the radium emanation is present in springs and in well water. Bumstead and Wheeler found that the air and surface waters of New Haven, Conn., was impregnated with the radium emanation. Strutt and Allan have observed that the famous Bath springs contain a considerable amount of radium emanation, and the former has also shown that the water contains a minute amount of radium in solution. A similar result has been noted for the waters at Baden and elsewhere. It has been suggested that the curative properties of these hot-water springs may possibly be due to the

presence of radium or the radium emanation. This has, however, by no means been established.

The atmosphere is found to always contain a small quantity of the radium emanation. This does not come from the atmosphere itself but diffuses up from the soil or is carried up by spring water. A large amount of investigation has been carried out to determine the amount of emanation present in the atmosphere at different localities and under varying atmospheric conditions.

It has been suggested that the internal heat of the earth may be, in part at least, kept up by the heat liberated by the radium and other radioactive matter present in it. Observations, that have so far been made, seem to show that the amount of radium in the surface crust of the earth is sufficient to supply as much heat to the earth as is lost by conduction to the surface from the hot interior of the earth. It is only necessary that radium should exist in the earth to the extent of four parts in one hundred million to account for the maintenance of the internal heat of the earth. The amount of radium or equivalent amount of other radioactive matter present in the earth cannot be greater than 270,000,000 tons or otherwise the earth would be growing hotter.

It is not possible to discuss here the physiological actions that are produced by radium rays. A large number of experiments have already been made and the literature of this branch of the subject is already extensive and is very rapidly growing. For bibliography see RADIUM.

ERNEST RUTHERFORD,

Revised by BERTRAM B. BOLTWOOD, Professor of Radio-Chemistry, Yale University.

RADIOLARIA, a group of minute one-celled organisms which secrete shells of silica. These shells accumulate in great abundance, and where they make up 20 per cent or more of the bottom sediments are called radiolarian ooze. This material covers large areas in the Pacific and Indian oceans.

RADIOLARIAN OOZE. See RADIOLARIA.

RADIOMETER, an instrument used to measure mechanical effect of radiant energy. It consists of four crossed arms of very fine glass, having at their extreme ends thin vanes of mica, blackened on one side, the blackened sides all facing the same way around the axis. The instrument is suspended by a quartz fibre in a glass vessel exhausted of air. When the vanes are exposed to rays of light or heat the wheel moves more or less rapidly in proportion to the strength or weakness of the rays. The phenomena of this radiometer (known as Nichols' radiometer, after its inventor) as determined by Maxwell, were shown to depend on the absorption of heat by the blackened sides of the vanes. This heat being transmitted to the particles of rarefied gas remaining in the exhausted globe caused them to thrust against that side of the vane and so cause a revolution. The instrument has certain advantages, but is very slow as compared with the bolometer, radio-micrometer and thermopile, requiring from 12 to 45 seconds for a maximum swing. It is, however, dependably accurate, on a single reading.

RADIOPHONE, an instrument that transmits or produces sound by means of radiant energy, particularly a device similar to the photophone, whose receiver is a block of vulcanite, with no telephone, the vibratory contraction and expansion being produced by the heat of the beam while vibrating, which is accompanied by an audible sound.

RADISCHEV, Alexander Nikolaievich, Russian author: b. Moscow, 20 Aug. 1749; d. Saint Petersburg, 11 Sept. 1802. He was descended from a noble Russian family, and after spending several years at court as a page, was sent to be educated at the University of Leipzig. He returned to Russia in 1771, and obtained a position in the department of customs. He had been deeply impressed during his absence by the writings of the French philosophers of the time, and in 1790, under the influence of his liberal sentiments, he wrote his famous 'Journey from Saint Petersburg to Moscow,' patterned somewhat after Sterne's 'Sentimental Journey.' This work is a most striking picture of Russian serfdom as it existed at the time, and contains a plan of emancipation, all the more bold for its appearance in a period of reaction. The book was immediately confiscated and the author was exiled to Ilimsk, in the government of Irkutsk, by the Empress Catharine, but was allowed to return to Russia in 1796. He was made a member of the legislative commission in 1801 by Alexander I. Soon after his appointment he was seized by melancholic attacks during one of which he committed suicide. His writings were collected in six volumes (Moscow 1807-11), but permission to reprint the 'Journey' could not be got even then. Consult Anon., 'A. N. Radischt Schew' (in *Archiv für Wissen Schafliche Kunde von Rusoland*, Vol. XIX, p. 77, Berlin 1860); Baring, M., 'An Outline of Russian Literature' (New York 1914); Waliszewski, K., 'A History of Russian Literature' (New York 1900).

RADISH, several species of herbs of the family *Brassicaceae*. The common garden radish (*Raphanus sativus*) is thought to be a native of Asia, but is not known in a wild state. It is cultivated for its edible roots, which in various varieties may be red, white, gray, brown or black, and vary in form from turnip-shaped to parsnip-shaped. They reach edible maturity in from three weeks or less when forced. Radishes thrive best in rich, light, well-drained sandy loam. Out of doors the seed may be sown as soon as the soil can be worked, since the plants are very hardy. The seeds may be dropped about an inch apart, covered an inch deep, in rows a foot asunder in beds by themselves, or, as in market garden practice, may be sown between slower-growing crops, such as carrots, cabbage or peas. Sometimes they are even sown with the seed of parsnips, onions and other crops that are either slow to germinate or that are very inconspicuous when they first appear. They then serve to indicate the positions of the rows, so that cultivation of the other plants may begin much earlier; they must then be removed promptly to prevent injuring the main crop. For succession, the seed should be planted at intervals of a week or 10 days. Winter radishes are sown from midsummer to early

autumn, and when cold weather arrives are stored in pits or cellars like other roots. Clean cultivation is essential. A Japanese species (*R. candelatus*) is popularly cultivated in Asia for its long pods which are eaten raw or pickled. It is known as the serpent or rat-tailed radish. The pods are often a foot long. The roots are small, hard and inedible. The sea radish (*R. maritimum*) is more pungent than the garden species and is little known in American gardens. Horseradish (q.v.) belongs to a different genus, *Armoracia*. Many of the insects which feed upon cabbage, turnip, mustard and related plants also feed upon the radish. The best known is the radish maggot which is the larva of a brown fly (*Phorbia brassica*). The maggots tunnel in the fleshy part of the root and injure it for human food. Applications of fertilizers, especially quickly soluble ones, and rotation of crops have been recommended as preventives. Consult Bailey, 'Standard Cyclopedia of Horticulture.'

RADIUM (Lat. *radius*, ray), was discovered in 1898 at Paris by Prof. Pierre Curie and Madame Skłodowska Curie in collaboration with Monsieur Bémont. It is the most important of over 30 newly discovered radioactive elements, and was found in the sulphate residues from pitchblende of the Austrian mines at Saint Joachimsthal, Bohemia, which had previously been worked for the metal uranium. Radium is a chemical element, symbol Ra, atomic weight 226.0, atomic number 88, very similar to barium in its chemical properties. Radium accompanies barium in many chemical reactions and is separated from it by repeated fractional crystallization of the salts, usually the chloride or bromide, the radium being enriched in the crystal fraction. A sufficient number of repetitions of the crystallization results in a pure radium salt, from which the atomic weight of radium and its spectral lines have been determined. The salts of radium most commonly prepared are the chloride and bromide (both readily soluble in water), the carbonate (soluble in acids) and the sulphate (insoluble—100 times less soluble than barium sulphate). The salts are white when freshly prepared, have the same crystalline form as the corresponding barium salts, but on standing rapidly change to yellow or brownish tints owing to the effect of their own radiations. The glass or silica tubes in which radium salts are usually retained also become colored by the radiations. The color is usually a bluish or deep violet, but some varieties of glass are colored brown. The color may be removed by raising the glass in temperature to a dull red glow. A most striking property of radium is its continual emission of radiations and heat. The heat emission from one gram of radium element amounts to 132 small gram calories per hour. It was by means of its radiations that radium was originally discovered and by means of them that it can be detected in extreme dilution. For example, in the ordinary commercial ores containing radium its content is about one part in 150,000,000 by weight. None of the ordinary elements could be detected at this dilution and their concentration or recovery in a state of purity would be impossible. Radioactive elements emit three kinds of rays named for the first three letters of the Greek alphabet

—alpha, beta and gamma. The first two, being really corpuscular in nature, are more properly termed alpha and beta particles. Alpha particles have been proved to be helium atoms with a double positive charge of electricity, and are emitted at very high velocities, one-fifteenth to one-twentieth of the velocity of light. Beta particles are electrons (single negative charge of electricity), and are emitted at various velocities from almost zero to that of light as a maximum. Gamma rays are ether vibrations (like ordinary light) but are of very short wave length and correspondingly high penetrating power. Those of the shortest wave length are 10 times more penetrating than the most powerful X-rays. The continuous emission of heat and radiant energy by radium at first greatly perplexed all scientists, as it appeared to controvert the law of the conservation of energy. The true explanation was proposed in 1903 by Rutherford (Sir Ernest E.) and Soddy (Prof. Frederick) on the hypothesis of atomic disintegration or spontaneous transmutation of one element into another, accompanied by the emission of radiation. This theory has subsequently been tested from all possible angles and has not only received the strongest experimental confirmation, but has initiated a new area of progress in the study of the constitution matter; and has incidentally placed the atomic theory on a solid basis of fact.

According to the theory of radioactive disintegration of the atoms, radium is only one member of the family of linear descendants from the parent element uranium (atomic weight 238). Each atomic change in the series is accompanied by the emission of a beta or an alpha particle, giving rise to an atom of the next lower member in the series, a new chemical element wholly different in properties from the parent. These changes proceed with the utmost regularity according to a very definite law, namely, that the same fraction of change always takes place in the same interval of time (logarithmic equation). The interval in which 50 per cent of the element changes is called its half period, a very fundamental physical constant, since the rate of change is independent of all physical or chemical conditions, such as temperature, pressure and concentration. The phenomenon is strictly a property of the atom. Therefore, all radium salts have the same radiations as the radium metal itself. The metal was once prepared in a pure state by Mme. Curie and was found to have all the properties to be expected of a base metal like barium. On account of the ease with which it oxidizes in air, it must be maintained in an atmosphere of hydrogen. The table on following page shows all the members of the uranium-radium family in their order of succession, their radiations, half periods and atomic weight.

Only a few of the interesting deductions possible from this table can be pointed out. On account of the genetic relationship between radium and uranium, the former will be found in nature only when associated with the latter, and always in the same ratio, namely, that of the two life periods to each other, or about one part of radium to three million parts of uranium by weight. This fact has been verified by examination of different uranium minerals from various parts of the world.

Whenever an atom emits an alpha particle it loses an atom of helium and hence its atomic weight is diminished by four units and its chemical valency by two units. The emission of a beta particle causes no change in atomic weight (since the mass of the beta particle is only one-seventeen hundredth of the atom of hydrogen), but the valency increases by one unit. These changes in atomic weight can be traced out in the accompanying table. That the atomic weight actually changes according to the theory has been verified experimentally for the atomic weights of uranium, radium and radium G (radiolead).

TABLE

MEMBER	Symbol	Half period	Rays	Atomic weight
Uranium ₁	U.....	5 billion years.	α	238

Radium Emanation.—The first disintegration product of radium is the only gaseous member of this series. It is given off from all solutions or fusions containing radium, and more or less freely from radium salts and ores. It has been estimated that the total quantity of radium emanation in the atmosphere corresponds to 10⁷ grams of radium. Radium emanation was named niton (shining) by Sir William Ramsay, signifying its property of emitting light; and also by the termination on that it belongs to the series of noble gases such as argon, krypton and xenon. Radium emanation is used in measuring small quantities of radium, also for therapeutic purposes frequently where the element itself was formerly used. On account of its very short life compared with the parent radium it must be collected at frequent intervals from the parent solution of radium salt to compensate its rapid rate of decay. Since the gas has all the properties of an ordinary gas it diffuses, when not confined to the surroundings and deposits its solid disintegration products, radium A, B, C, etc., on any object, thus imparting apparently radioactive properties termed "induced activity" but now more correctly referred to as *active deposit*. The first three members below emanation in the series, radium A, B and C, accumulate in a confined volume to maximum quantity in about four hours.

The practical uses of radium are confined

to two classes: (1) therapeutic and (2) for the production of luminous products by mixing with phosphorescent zinc sulphide. The therapeutic use of radium was suggested by the physiological effects of its rays which are very marked. Prolonged exposure to large quantities of radium produces painful and even fatal burns. By controlling the quantity of radium, the time of exposure and the thickness of metallic screening, radium may be used for the treatment of malignant growths, such as cancer, through the effect of its radiations. Some remarkable results have been achieved in this direction but much experimentation is required to determine all the physical factors involved in obtaining the best results. Radium therapeutics may still be regarded as in the experimental stage, and is much hampered by the scarcity and high cost of radium.

By mixing a small proportion of radium with an especially prepared phosphorescent zinc sulphide, a fairly permanent luminescent material is produced which can be applied to the dials of instruments or to any other surface which it is desired to render self-luminous in the dark. During the European War such material was extensively employed on airplanes, battleships and in the trenches since it had the advantage of illuminating dials, gun sights, etc., without exposing a light to the enemy, since the luminosity, even that from the strongest preparations, can be seen at a distance of only a few yards. The proportion of radium employed in preparing the luminous materials depends on the luminosity desired. About one part of radium element per 4,000 parts of zinc sulphide is the upper limit for radium. Much lower mixtures than this can be used for many purposes. The luminosity of radium paint increases for about three weeks after preparation and then falls off for some months, finally reaching a value about 20 per cent of the original brightness which appears to remain constant for several years at least.

The natural sources of radium are principally the three uranium ores—carnotite, uraninite (pitchblende) and autunite. Carnotite (a vanadate of uranium) is found extensively in the arid regions of southwestern Colorado and southeastern Utah and now constitutes by far the most important source of radium. It is estimated that more than 55 grams (or about two ounces) of radium element have been produced from this source. The principal source of pitchblende has been the Austrian mines of Saint Joachimstahl. Some radium has also been prepared in France from autunite (a phosphate of uranium), found in France near Autun and also in Spain. See RADIOACTIVITY; POLONIUM; URANINITE; URANIUM, etc.

S. C. LIND,
Physical Chemist, Bureau of Mines, Mining Experiment Station, Golden, Colo.

RADIUM THERAPY. Twenty years after Madame Curie announced the discovery of radium, and 15 years of experience with its use in treatment of diseased conditions, is long enough to give some idea of its usefulness and its limitations. Radium came into use as a surgical agent some five years after the discovery and similar application of the X-ray. The latter had already demonstrated its efficiency in curing some, and ameliorating other types of malignant disease, and it was at once surmised that radium might have similar effective force, inasmuch as its output of peculiar energy was not unlike that from X-ray tubes. Exaggerated hopes and claims for both have been modified with time, and one can now estimate somewhat the worth of both. The limits of its usefulness have not yet been reached,—not only in the field of malignant disease but in other types of non-malignant tumors and skin diseases.

Everyone who aspires to the use of radium efficiently must have some fundamental knowledge of its effect on the vital growth of living, healthy cells. Without such intelligent understanding, one is not prepared to ask what happens in treating diseased cells. A series of simple experiments with garden seeds or bulbs will demonstrate convincingly the retarding effect on cell growth after exposure to radium. For example, if strong radium be placed an inch distant from any seed chosen, before planting, for from two to eight hours, these, after planting, will grow in size and vigor exactly in proportion to the time of exposure,—the longest treated may be killed, the shortest may be scarcely retarded, the middle series will grow half the normal height.

This gives the clue to the results seen in tumors. It is admitted that cell growth, whether vegetable or animal, is actuated by the same vital force. Tumors are merely the massive and exaggerated growth of cells, which are found normally at the site of the tumor. The popular expectation that large tumors can be easily removed by radium is not borne out by facts; but early treatment of small growths of typically malignant cells is successful in every-day practice, because, at that stage, there has been no wide dissemination of the disease. When the magnitude of the growth is too large for radium then surgery can remove it by knife or caustic, which only serves to emphasize the wonder of radium work, which can so alter wrong growing cells as to restore them to healthy action when small, without removing them as caustics, cautery and the knife do.

There are types of low-grade, malignant tumors which uniformly cure themselves after proper doses of radium therapy, and there are also other grave forms which yield to radium. Starting from and among the marrow cells of the bones, proceeding by absorption and destruction of the bone, if not arrested, the so-called myeloid tumors, wonderful to relate, disappear under radium treatment and new bone

re-forms in shape like the one that disappeared. In one patient under the writer's care a part of the bone of the lower jaw was entirely replaced by a tumor the size of a small hen's egg. When the radium had altered the cells they melted away, the bone was perfectly restored and has remained sound and well for 15 years. Again, tumors of lymph glands are well controlled by radium and often cured unless they be tubercular. The disease of all the lymph gland system, known as Hodgkins' disease, is well treated by radium as it is also by the X-ray.

It is among the wonders of modern surgery to witness the disappearance of tumors which have overgrown parts of the body, like the eye-lid or lip, and to watch the complete restoration of the original part. So completely does this illustrate the unique and subtle power of radium, that one example may be cited: A tumor had grown on the lower eye-lid so as to destroy all semblance of more than half of it. A fortunate use of the exact amount of radium necessary caused the complete disappearance of the tumor and perfect restoration of the eye-lid within eight weeks. For 10 years afterward it was impossible to say on which lid the tumor had been. This tells the story of the specific effect on disordered cells called tumors; where the healthy part was engulfed and lost in a malignant growth, whose wrong growing cells, being weaker, melted away under radium rays, and allowed a reassembling of the original healthy ones and restoration of the eyelid under its healing action.

This selective action against diseased tissue is now an accepted fact; alongside of that, however, is the discovery that many kinds of cells have such different degrees of resistance that only a few types of tumor yield to radium. The popular cry for a cancer cure is not met by any claim that its most ardent advocates can make for radium. This is not because the early growth of cancer cells is not controlled by radium, but because by the time the neglected trouble is brought to the notice of the surgeon, the system has been invaded beyond the reach of any remedy.

Methods of Applying Radium.—Very highly condensed radium salts in the form of carbonate, chloride, sulphate or bromide are incorporated with varnish and spread on metal surfaces of small size,—half an inch or one inch in diameter—or better still, fused with powdered glass in an indestructible enamel on a small metal surface; or the radium powder may be put in very fine glass tubes an inch long and as large as a steel knitting-needle; or, if dissolved in water, it will yield radium emanation which may be collected and condensed into glass capillary tubes scarcely larger than a pin, which, when protected by a delicate silver case, may be buried in tumors or laid upon the surface. Again, the minutest solution of radium in sterile water may be injected beneath the skin with a hypodermic needle and a systemic effect can be produced,—(lowering of blood pressure, etc.); but the efficacy of this in any disease is, as yet, very problematical. Of late, also, there has been an attempt made to isolate the beta rays from radium, separated in large quantity in the magnetic field and projected upon diseased surfaces (psoriasis, etc.), with striking alterative effect. The beta ray has

been demonstrated to be the efficient factor in radium work. All methods, however, of using this extraordinary agent are still subject to change.

Two facts are established: First, surface diseases can be treated by strong radium placed on the surface for a half hour, with gauze, paper or cotton interposed to the thickness of a quarter or of half an inch, as a filter to exclude the most irritating rays; second, when the disease is deep, insulation of the skin, which is a natural protector, prevents penetration of the efficient rays to a sufficient depth, without such a long application as would injure the skin, unless a thick screen of lead is interposed to cut off the burning rays and allow penetration of the gamma, which generate secondary beta rays.

About one-tenth millimeter of lead for every hour's exposure of small amounts of radium (up to 100 milligrams) is about the correct screen to affect deep structures. With these facts in mind experience will dictate the carefully gauged dosage of rays which must be discharged into the structure to produce a curative action.

Speculation would lead one to surmise that, if its curative effect lies in the negative electrons which radium supplies, the disease might be due to the loss of the negative charges. Granting that the force activating any living cell is a well-balanced positive and negative charge of electricity, the equipoise is re-established by restoring the lost part with permanent benefit. While physiologists are in doubt whether the chemical change in metabolism of living tissue creates electric action, or, whether latent electric forces engender chemical changes and biologic metabolism, it would seem that this clean-cut supply of one electric element, with its resultant good, brings us one step nearer to understanding why cells grow and why they grow wrong. Inferentially, electricity and not biological change is the primary driving force. In summarizing the acknowledged efficiency of radium results in surgical work, the most clear-cut demonstration of its value is shown in the cure of many semi-malignant tumors of the skin—notably of face, scalp and hands; in the alterative and reducing effect on lymphoid structures, lymph gland tumors, lymphangiomata of tongue, parotid, thyroid and splenic tumors; in complete disappearance of bone myeloid tumors; in prompt and complete disappearance of papillomata—warts in any part, especially available in the larynx where one application is usually sufficient; in alterative and often curative effect in patches of chronic itching eczema, psoriasis, Paget's nipple, vernal catarrh and keloids.

The public call on scientific medicine to find a cancer cure has been met with untiring zeal by thousands of earnest students. One use of radium lies in helping to understand the subject better and to differentiate the various types of that multiform disease; but as yet its use meets with a limited response. There is undoubtedly a curative action on small groups of cancer cells when found in nests in the neighborhood of larger growths. It may also be said that when radium is buried in the area from which a cancer has been imperfectly removed, it has sometimes shown curative action and has prevented recurrence, but as a weapon against

considerable cancer masses it is not yet available. In mixed cancer tumors where adenoid structure exists, as in adeno-carcinoma of the rectum, it has a marked retarding value when properly used. Exact methods of applying this powerful agent have yet to be formulated and great experience and judgment are necessary to obtain the beneficial action of this remedy.

ROBERT ABBE, M.D.

RADIUS, the bone of the fore limb of vertebrate animals, which, as in man, when the arm is laid flat with the palm upward, lies to the thumb side of the limb. This side is, therefore, termed the *radial* side of the limb, in contradistinction to the *ulnar* or opposite side, so named from the ulna or neighboring bone, which, with the radius, constitutes the forearm. See **ARM**.

RADIUS, in geometry. See **DIAMETER**.

RADIUS BAR, or **RADIUS ROD**, one of the guiding-rods in a parallel motion, jointed to the connecting links, to counteract the vibratory motion communicated by the beam by guiding the links so that the head of the piston rod may reciprocate in a line sensibly straight.

RADIUS OF CURVATURE. See **CURVES OF DOUBLE CURVATURE**.

RADIUS VECTOR. See **MATHEMATICS**.

RADIX. See **Root**.

RADOM, *rădôm*, Poland, (1) city and capital of the government of same name, on the right bank of the Radomka (or Mleczna) and on the Ivangorod-Dombrova Railroad, 100 miles south of Warsaw, and one of the best-built provincial towns. Its special features are an ancient church and convent and the ruins of an old castle. The town is supposed to have been founded about 1350 by Casimir the Great, king of Poland. It has played an important part, at various times, in the history of Poland (q.v.), being frequently the seat of Polish diets. It was captured by the Germans in the early part of Great War. Its manufactures are of tin, oil, vinegar and leather. Two fairs are annual attractions. Pop. about 50,730. (2) The government covers an area of 4,768 square miles, and has a population of 1,180,200, chiefly Catholics. Its chief rivers are the Vistula and Pilica. It is divided into seven districts. Although there are extensive marshes, a large part of its soil is very fertile, about 50 per cent being under cultivation and 28 per cent under forests. Wheat, rye, barley, oats, buckwheat, hemp, flax and potatoes are the main crops and a considerable amount of grain is exported. There is also extensive raising of livestock. The government is rich in iron ore and other minerals and important industrial establishments employing some 75,000 workmen have been developed.

RADOWITZ, Joseph Maria von, Prussian statesman: b. Blankenburg, Germany, 6 Feb. 1797; d. Berlin, Germany, 25 Dec. 1853. He was of a noble, originally Hungarian, family, and in 1812 entered the Westphalian army as an officer and was wounded and taken prisoner in the same year at the battle of Leipzig. In 1823 he entered the Prussian service, and in 1830 became chief of the general staff of artillery and a leader of the anti-revolutionary party. He subsequently held diplomatic posts at Carlsruhe, Darmstadt and Nassau, was the

confidant and adviser of King Frederick William IV, and after the revolution of 1848 supported the efforts of Prussia to give a constitution to Germany. For a few months in 1850 he was Prussian Minister of Foreign Affairs. In August 1852 he became Director of Military Education. He wrote several works, mainly political, which include 'Ikonographie der Heiligen, ein Beitrag zur Kunstgeschichte' (Berlin 1834); 'Gespräche aus der Gegenwart über Staat und Kirche' (Berlin 1846); 'Deutschland und Friedrich Wilhelm IV Devisen und Mottos des Späteren Mittel-Alters' (Berlin 1850); 'Neue Gespräche aus der Gegenwart' (Berlin 1851). Consult Frensdorff, E., 'Joseph von Radowitz' (Leipzig 1850); Hassel, 'Joseph Maria von Radowitz' (Berlin 1905); Liliecron, R. von, 'J. M. von Radowitz' (in 'Allgemeine Deutsche Biographie,' Vol. XXVI, p. 141, Leipzig 1888).

RADZIWIŁŁ, rād'zē-vil, ancient, very wealthy Lithuanian-Polish family, descended from Nicholas I (1366-1446), voivode of Vilna. Its members became princes of the empire in 1556. Among its most famous members are: (1) Nicholas VI the Black, son of John the Bearded and palatine of Vilna (1515-65), from whom the modern Radziwiłłs are descended. King Sigismund Augustus gave him the command, in 1552, in the war against the Polish knights. He also commanded in the war against Russia in 1561. Having become a convert to the Reformation, he financed the translation of the Bible into the Polish tongue and its publication (Biblia swieta, Brzesc 1563). (2) Christopher II, military governor of Lithuania and palatine of Vilna, b. 1585; d. 1640. After the death of Sigismund, in 1632, he undertook the defense of the Protestants at the diet of Warsaw and obtained complete toleration for them. Enjoying the confidence of Vladislav IV, he commanded in the war against Russia. (3) Boguslav, Prince Radziwiłł, son of Prince James and Sophie Elizabeth, margravine of Brandenburg, was governor in Prussia, 1657-69, and rendered important services in endowments to universities and schools. (4) Charles, Prince Radziwiłł, palatine of Vilna and grand-commander of Lithuania: b. 1734; d. 1790. He was the enemy of Czartoryscy and the Russians and an adherent of the Saxon party. He was an ardent supporter of the Confederation of Bar and was several times exiled. For three years he was a member of the constituent diet at Warsaw. In more modern times many of the members of the family have occupied important military, diplomatic and political posts at the Prussian court. Some branches of the family, however, attached themselves to the Russian court. (5) Michael Geron, Prince Radziwiłł (1778-1850) fought under Kosciuszko and Napoleon I against the Russians. (6) Elsie, Princess Radziwiłł (1803-34) became the object of a youthful love on the part of William I, German Emperor. Her nephew, (7) Anton (1833-1904) was attached for many years to the immediate entourage of the latter. Consult Anon., 'Die historische Stellung des Hauses Radziwiłł' (Berlin 1892).

RAE, rā, Charles Whiteside, American naval engineer: b. Hartford, Conn., 30 June 1847; d. Washington, D. C., 13 May 1908. He was graduated at the Rensselaer Polytechnic

Institute in 1866 and at the United States Naval Academy in 1868. He remained in the navy, receiving regular promotion, becoming captain 3 Jan. 1903. In the Spanish-American War he served at the bombardment of San Juan, Porto Rico, and at the naval battle of Santiago, 3 July 1898, receiving a medal and promotion for his services. He was appointed engineer-in-chief of the United States navy, with rank of rear-admiral and chief of the Bureau of Steam Engineering in the Navy Department, 9 Aug. 1903.

RAE, rā, John, Scottish explorer: b. near Stromness, Orkney Islands, 30 Sept. 1813; d. London, 22 July 1893. He studied medicine at Edinburgh, became surgeon in the Hudson's Bay Company's service in 1833, and from 1835 till 1845 was the company's resident surgeon at Moose Fort. In 1846-47 he made his first exploring expedition, covering 700 miles of the northern coast of America along Committee Bay. He then went to London and in 1848-49 accompanied Sir John Richardson in his Franklin search in the Mackenzie and Coppermine region. He conducted two expeditions in 1851, during the first of which he explored a large part of the coast of Wollaston Land. During the second he traveled a distance of over 5,000 miles in eight months and explored much of the coast of Victoria Land. In 1853-54 he again conducted an expedition and discovered the first traces of Franklin's fate, for which the party received the government grant of £10,000. He also proved King William's Land to be an island. In 1858, 1860 and 1864 he was member of expeditions to the American Arctic regions. In all he walked 23,000 miles and explored coast lines aggregating over 1,700 miles. Consult Richardson, 'Arctic Expeditions' (London 1852-53) and 'Polar Regions' (ib. 1861). He published 'Narrative of an Expedition to the Shores of the Arctic Sea in 1846-47' (1850).

RÆBURN, rā'bērn, Sir Henry, Scottish portrait painter: b. Stockbridge, near Edinburgh, 4 March 1756; d. there, 8 July 1823. He was left an orphan at an early age and was apprenticed to a goldsmith, who, perceiving his talent for drawing, encouraged him in his ambition to be an artist. The favorite portrait painter in Edinburgh at that time was David Martin, who was the only instructor Raeburn ever had. He formed his style, however, by copying in color, mezzotints from the paintings of Sir Joshua Reynolds, and while he learned the chiaroscuro of that master he never attained his almost Italian richness and solidity of coloring. His drawing was correct, but unfortunately acting under the idea that a portrait was to be viewed at some distance above the level of the eye, he foreshortened the forehead and brought forward the nostrils and lower jaw. Thus Sir Walter Scott complained that his portrait by this artist caused him to look "clownish and jolterheaded." Acting on the advice of Reynolds, Raeburn spent two studious years in Italy (1785-87) which resulted in a marked improvement in his coloring, which had previously been thin and undecided. Wilkie actually wrote from Spain that the execution of Velasquez reminded him of Raeburn. His 'Portrait of Mr. William Forsyth' in the New York Metropolitan Museum is a fair specimen of his style and there are two

pictures of his in the New York public library. Another fine portrait may be seen in the Art Museum, Worcester, Mass. He confined his serious artistic efforts entirely to portraits and painted every eminent Edinburgh man of his day. Among his sitters were Jeffrey, Stewart, Braxfield, Erskine and Sir Walter Scott. In 1812 he was made president of the Royal Society of Artists of Scotland and three years later was elected to the Royal Academy. He was knighted by George IV in 1822. The public galleries of Edinburgh and Glasgow have several of his works. He is also well represented in the National Gallery, London, the Royal Academy and many private collections in England. The Morgan collection (New York) contains two of his masterpieces. Consult Armstrong, W., 'Sir Henry Raeburn' (London 1901); 'Masters in Art' (Vol. VI, Boston 1905); Clouston, R. S., 'Sir Henry Raeburn' (New York 1907); Greig, James, 'Sir Henry Raeburn: His Life and Works' (London 1911).

RAFF, räf, Joseph Joachim, Swiss composer: b. Lachen, Switzerland, 27 May 1822; d. Frankfurt-on-the-Main, 24 June 1882. He was educated at Wiesenstetten in Würtemberg and at the Jesuit Lyceum in Schwyz, and gained the notice of Mendelssohn and Liszt. In 1850 he removed to Weimar in order to be near Liszt, and his opera 'König Alfred' was shortly afterward produced at the Court Theatre there with great success. In 1877 he was appointed director of the Conservatoire at Frankfurt, a position he occupied until his death. He was an indefatigable worker, his compositions numbering over 200, and his reputation rests chiefly upon his symphonies, among which are 'Im Walde'; 'Lenore'; 'An das Vaterland,' etc. He was also very successful as a song-writer, and a notable composer of instrumental pieces, but his three operas were less successful. Though not confining himself to any one style of composition, he was a supporter of the Wagner school.

RAFFAELLO, rä-fä-ël'lo. See RAPHAEL.

RAFFIA. See FIBRE.

RAFFLES, räf'lz, Sir Thomas Stamford, English colonial administrator: b. at sea, off Point Morant, Jamaica, 5 July 1781; d. Highwood, near London, England, 5 July 1826. He was employed in the East India House as a clerk when 14, soon attracted attention by his ability and in 1805 was appointed assistant secretary at Penang. He mastered the Malay language while on the voyage and in 1807 was appointed secretary and registrar of the Recorder's Court. He visited Malacca in 1808, and in 1810 went to Calcutta where he met Lord Minto, the governor-general, and by his advice the expedition against Batavia was fitted out in 1811. He accompanied Lord Minto to Java in that year and after its capture from the Dutch became its lieutenant-governor, an office which he held for five years. His administration was eminently wise and successful; he retained the Dutch colonial laws, but abolished forced labor and instituted marked improvements in taxation and the administration of justice. He returned to England in 1816 when the island was given up to the Dutch, was knighted and commissioned by the prince regent to proceed to Holland to confer with

its king in regard to the government of Java. In 1818 he was appointed governor of Benckulen in Sumatra, where he found many abuses existing. He abolished slavery, reorganized the government of the colony, founded schools and otherwise greatly improved the condition of the island. He explored with Joseph Arnold the interior of the island and discovered the great fungus named in their honor *Rafflesia Arnoldi*. Ill health compelled his return to England in 1824 and on the voyage the ship caught fire, destroying his natural history collection, manuscripts, drawings and notes valued at \$100,000. He was first president of the Zoological Society. He published 'History of Java' (1817), and 'Malayan Miscellanies' (1820-22). Consult Lady Raffles, 'Memoir of Sir T. S. Raffles' (1830); Egerton, 'Sir Stamford Raffles' (in 'Builders of Great Britain' series).

RAFFLESIA, an East Indian genus of parasitic plants, reduced to apetalous dioecious flowers and named after Sir Stamford Raffles, the discoverer. *R. Arnoldi* was the first species discovered in Sumatra. It is a gigantic flower, springing from the roots or stems of *Vitis (cissus)*, three feet in diameter and consisting of a globular central cup, containing either the ovary, or the numerous stamens, crowned by a ring, and the five-lobed calyx, fleshy and flesh-colored, blotched with pink and yellow inside and with brownish or bluish scales exteriorly. The whole flower sometimes weighs 15 pounds. It remains expanded for a few days only, and then decays, emitting a putrid odor that attracts carrion-loving flies, which probably assist in cross-fertilization. The fruit is a brown, rough surfaced nut, holding innumerable seeds. Certain Javanese species are valued there as powerful styptics.

RAFINESQUE, rä-fë-nësk', Constantine Samuel, American botanist: b. near Constantinople, Turkey, 1784; d. Philadelphia, Pa., 18 Sept. 1842. He was of French-German parentage and was sent to America in 1802 where he made botanical investigations in Pennsylvania and Delaware and in 1805 returned to Turkey with botanical specimens. While sailing for the United States in 1815 he was shipwrecked off the coast of Long Island and lost his collection of 20 years. He settled permanently in the United States in 1815, and was made professor of botany in Transylvania University, Lexington, Ky., in 1818. Later, after lecturing in various places, he removed to Philadelphia. He was a man of wide learning, but his work is in many instances rendered confusing by his insatiate desire for novelties, and though evincing keen insight is frequently inexact. His publications include 'Ancient History, or Annals of Kentucky' (1824); 'Medical Flora, etc., of the United States' (1828-30); 'A Life of Travels and Researches in North America and South Europe' (1836); 'Pleasures and Duties of Wealth' (1840), etc. Consult Call, R. E., 'Life and Writings of Rafinesque' (Louisville 1895).

RAFT, a floating platform, usually composed of wooden logs or planks, fastened together by nails, spikes or cordage, and used either as a vehicle of travel and for the carriage of goods, or more generally for the purpose of transporting by river, lake or sea the materials composing the raft from the place of its construction to a market for sale. In all probability

the raft was the first human method of travel on water, next to floating on a large branch or tree-trunk, the use of which would naturally suggest the raft, just as a raft, with sail of skin or other material raised to catch the wind, would suggest the first rude sail boat or ship. Rafts have been in use in all historic ages, and doubtless far back in the prehistoric period, but they reached their most general use after the settlement of North America, when the vast forests were being cleared by settlers, and the raft offered almost the only method by which the pioneer on the Ohio or Mississippi could reach the settlements on those rivers, dispose of his surplus products, and buy some of the comforts and perhaps luxuries to be obtained in the towns. The steamboat has almost entirely done away with the raft as a means of travel, but rafting is still the chief method of conveying the lumber product of northwestern forests to market, and immense rafts are sometimes sent by sea from Maine to New York or Boston. On the Pacific Coast also the rafting business is most extensive. In the fall of 1902, a monster raft 700 feet long, 53 feet wide, 12 feet from the water's edge to the top, and drawing 22½ feet of water was safely towed 700 miles from Columbia River to San Francisco. The logs were 120 feet long, and from 12 to 20 inches in diameter, and there were in all 7,000 pieces, valued at \$60,000. The construction of a raft of this size is a vast undertaking. A great "cradle" of heavy timbers is built on a slough connected with the Columbia River. A row of piling is driven in deep water, and the frame of the cradle floats up and down on the row of piling, and is held in place by it. A large scow with a derrick is anchored beside the cradle. Log-booms or small rafts are towed to it, and the logs are lifted by the derrick into the cradle, where they are fastened with chains and cables, from 80 to 100 tons of chain being used on one raft. When the raft is finished the keys that held the parts of the cradle together are drawn, the side of the cradle is pulled away, and the raft floats out on the water. Tugboats draw it into and down the Columbia, and out to sea on its voyage to the Golden Gate.

RAGATZ, rä'gäts, Switzerland, a fashionable Spa in the province of Saint Gall on the Tamina, celebrated for its hot springs, mineral waters and scenery. About 50,000 tourists visit Ragatz every year. Pop. 2,063. See **PFAFERS**.

RAGGED ROBIN. See **LYCHNIS**.

RAGGED SCHOOLS, a name given in Great Britain to those institutions supported by voluntary contributions for the education of neglected children and the consequent prevention of juvenile crime. The idea of forming such schools was due to a Portsmouth cobbler, John Pounds, who about 1819 began to take in the ragged children of the district in which he lived and teach them while he was at work. This he continued till his death in 1839. The success of the plan caused a number of more influential persons to take the matter up, and in 1838 a ragged Sunday-school was opened in London. In 1841 the first feeding-school, in which the children are not only educated but kept and fed for the day, was started in Aberdeen. What gave a greater impetus than any-

thing else to the ragged school scheme was Dr. Guthrie's 'Plea for Ragged Schools,' published in 1847. It had an immense circulation, and was followed by the extension of the system to every considerable town in the kingdom. The name ragged schools was first adopted in 1844. Owing to the education acts, and especially the introduction of compulsory school attendance and abolition of fees, many of these schools were absorbed by the school-boards, and generally they may be said to be a thing of the past.

RAGHUVAMŚA, rä-g-hoo-vän'sha, one of the two epics of the Sanskrit poet Kālidāsa (q.v.). Its subject is the legendary history of the solar kings, or kings descended from the sun. See **SANSKRIT LITERATURE**.

RAGIE, a grain. See **ELEUSINE**.

RAGLAN, Fitzroy James Henry Somerset, LORD: b. 30 Sept. 1788; d. Sebastopol, 28 June 1855. In 1804 he entered the army and in 1807 served on Wellington's staff in the expedition to Copenhagen, while throughout the Peninsular campaign he served as military secretary. In 1814 he acted for a short time as secretary to the embassy at Paris, and from January to March 1815 was minister plenipotentiary there. At Waterloo he lost his right arm. From 1827 to 1852 he was military secretary at the Horse Guards, in 1852 became master-general of the ordnance and in October of that year entered the House of Peers as Baron Raglan. He was commander of the English forces in the Crimean War, where he suffered much from the early failures of the campaign and from the hostile criticism of the inefficient commissariat arrangements. Consult Kinglake, 'Invasion of the Crimea.'

RAGMAN ROLLS, documents containing a record of the acts of allegiance extorted by Edward I of England from the nobility and gentry of Scotland in 1291-92 and 1296. The document was delivered back to the Scotch along with other records and muniments in 1329 in terms of the Peace of Northampton, when the independence of Scotland was formally acknowledged. It is now deposited in the British Record Office.

RAGNARÖK, räg'na-rék, in Scandinavian mythology the day of doom when the present world will be annihilated, to be reconstructed on an imperishable basis. The title of the concluding portion of Wagner's great operatic trilogy 'Götterdämmerung' is a translation of this word. In that work is depicted the downfall of Woden and the gods and the triumph of perfect human love. William Morris also treats this subject in his 'Sigurd the Volsung.' 'Ragnarök' is the title of a novel by Ignatius Donnelly.

RAGOZIN, rä-gō'zën, Zenāide Alexeievna, Russian-American writer: b. Russia, 1835. She traveled widely in Europe and in 1874 came to the United States. She is a member of the leading American and European literary societies, and has achieved a wide reputation as an author. Her most important books are 'The Story of Chaldea' (1886); 'The Story of Assyria' (1887); 'The Story of Media, Babylon, and Persia' (1888); 'History of the World'; 'Siegfried, the Hero of the Netherlands' (1898); 'Roland, the Paladin of France'.

(1899); 'Salamambo, the Maid of Carthage' (1899).

RAGS, though valueless for most purposes, are yet of great importance in the arts, particularly in paper making. Woolen rags of a loose texture, and not too much worn, are unraveled by means of machinery, and mixed up with good wool, to form what is known as "shoddy," with which cheap woolen goods are made.

RAGTIME, a musical term of American origin signifying a rhythm or movement of inversions of emphasis and irregular accents, a sort of continuous syncopation and somewhat similar to "Scotch catch" or "snap." It was formerly applied to the negro melodies of southern United States and to songs and dances caricatured from them, but has been extended in colloquial use to cover any popular song of similar melody. The music itself is supposed to have originated through the limitations of the crude African musical instruments, the emphasized accents being effective on instruments of percussion.

RAGUENEAU, rāg-nō, Paul, French missionary and explorer: b. Paris, 1608; d. there, 3 Sept. 1680. He joined the Jesuit order, and went to Canada in 1636 to work among the Indians, first visiting the Hurons. In 1640 he made an unsuccessful attempt to secure the release of French prisoners from the hostile Iroquois. Becoming the head of the Jesuit missions in Canada in 1650, he brought the remnant of the Hurons to Quebec to escape the Iroquois. On a visit to the Onondaga tribe of Iroquois he nearly lost his life. His chief success was with the Hurons, with whom he labored until 1666, when he returned to France and acted as agent for the Canadian missions. He wrote 'Vie de la Mère St. Augustine, religieuse, Hospitalière de Quebec en la Nouvelle France' (1672); 'Relation de ce qui s'est passé de plus remarquables des Missions des Pères de la Compagnie en la Nouvelle France' (1647-57), the latter work covering the years 1645-52 and 1656-57. Consult Parkman, 'The Jesuits of North America' (1867); 'The Jesuit Relations' (1896-1901).

RAGUET, rā-gā', Condy, American political economist: b. Philadelphia, Pa., 28 Jan. 1784; d. there, 22 March 1842. He was educated at the University of Pennsylvania, studied law, and later entered upon a commercial career. He went to Santo Domingo in 1804 as supercargo on a vessel and made a second voyage to that island in 1805. In 1806 he went into business on his own account and was eminently successful, amassing an immense fortune and playing an important part in the commercial affairs of the day. In 1812 he was active in providing for the defense of Philadelphia against the expected attack of the British fleet, and in 1815 was elected to the State legislature where he subsequently served in both houses. He was appointed United States consul at Rio Janeiro in 1822 and in 1825 became *chargé d'affaires* to Brazil, an office he occupied until 1827. After his return to the United States he edited several journals devoted to free-trade doctrines, among them *The Free Trade Advocate* in 1829; *Examiner* in 1834-35; *The Financial Register* in 1837-39; he also published two small volumes relating to Santo Domingo;

'Principles of Free Trade' (1835); 'On Currency and Banking' (1839), etc.

RAGUSA, rā-goo'sā (Slavic, DUBROVNIK), a seaport town of southern Dalmatia, Jugo-Slavia, on the Adriatic. It lies at the foot and on the slopes of Monte San Sergio and its streets rise in terraces from the Corso, the principal thoroughfare, which traverses the centre of the city. There are old walls flanked with towers and a fort erected during the French occupation in the beginning of the 19th century. Among the notable public buildings are the cathedral dating from the first years of the 18th century; the new Greek church; the older churches of the Franciscans, Dominicans and Jesuits; the town-hall, anciently the governmental palace, completed in the early part of the 15th century after nearly 100 years in building, and forming a magnificent example of the Gothic-Venetian style; and the Dogona, of the same architectural type. The industrial interests of the town comprise chiefly manufactures of silk, leather and liqueurs. The coasting trade is important, but owing to the shallowness of the harbor, centres chiefly at Gravosa, some four miles to the north. The population is about 14,291. Ragusa was founded in the 7th century by refugees from the ancient Epidaurus, now known as Ragusa Vecchia, when that city was destroyed by the Slavs. Ruled in turn by the Byzantines, the Venetians and the Hungarians, it acquired in the 13th and 14th centuries, through trade and unscrupulous diplomacy, lordship over a territory of some 750 square miles and maintained its existence as an aristocratic republic, paying tribute, after 1440, to the Turks. The prosperity of the town was undermined by several epidemics in the 16th century and by repeated earthquakes of which that of 1667 was the most disastrous. In 1806 Ragusa was occupied by the French, two years later the republican form of government was abolished, and in 1809, with the rest of Dalmatia, it was annexed to the Illyrian kingdom. In 1814 it passed to Austria. The see of Ragusa was founded in 980, and from 1121 to 1831 it was the seat of a Roman Catholic archbishop. Under the European Peace Treaty of 1919, Ragusa passed from Austria to the new republic of Jugo-Slavia.

RAGUSA, a town of Sicily, in the province of Syracuse, on the mountain stream Erminio, some 30 miles west-southwest of Syracuse. It has considerable manufactures of cotton and other textiles, oil, furniture and asphalt and carries on an important trade in corn and wine. It comprises two communities, Ragusa proper with a population of about 32,000, and Ragusa Inferiore with 7,850 inhabitants. Ragusa is supposed to be the ancient Hybla Heræa.

RAGWORT, any of various composite weeds of the genus *Senecio*, common in most parts of the world. These coarse, yellow-flowered plants are allied to the thistles, and some of the numerous American species are known as squaw-weed, ragwort, and butter-weed, and in England as groundsel. See *SENECIO*.

RAHL, rāl, Karl, Austrian painter: b. Vienna, 13 Aug. 1812; d. there, 9 July 1865. At 19 he won a prize at the Vienna Academy and then started on his first tour among the art

centres of Germany, Hungary and Italy. He made his home in the last-named country from 1836 to 1843, studying especially the painters of the Venetian and Roman school, from whom he derived the grandeur of conception and noble coloring for which his works are distinguished. In 1846, after two years' residence as a portrait painter in Vienna, he resumed his travels and practised his art with success and profit in Holstein, Paris, Rome, Copenhagen and Munich. Among his historical paintings of this first period are 'The Finding of Manfred's Body'; 'Manfred's Entrance into Lucera'; 'The Catacombs during the Persecution' (in the Hamburg gallery and a replica in the Berlin National Gallery). He was appointed professor in the Berlin Art Academy in 1850, but his political opinions were extreme and violent and he was compelled to leave the city. The private school which he thereupon opened became the most important seminary of painting in Austria. He meanwhile applied himself to much decorative work, as is testified by the painted façade and vestibule of the church in the Old Meat Market at Vienna, the four compositions from the Greek heroic age, and the 'Four Elements' in the palace of Baron Sina. In 1864 he painted in the Museum of Arms a series of allegorical figures of heroic size. To this period belong his fresco, 'A Maid from Foreign Lands'; and the designs for a ballroom in Oldenburg Castle and 'Incidents of the Argonautic Expedition.' His last works consisted of designs for the decoration of the New Opera House at Vienna. These were executed by his pupils after his death. He unites in his pictures the rich coloring of Rubens and Titian with a harmony of grouping monumental in its impressiveness. Yet his handling of form inclines to coarseness and exaggeration. Among the most eminent of his pupils were Bitterlich, Eisenmenger, Lotz, Griepenkerl, Gaul and Than. Consult George-Mayer, 'Erinnerung von Karl Rahl' (1882).

RAHU, rā'hoo, in Indian mythology the demon who is imagined to be the cause of the eclipses of sun and moon. Rahu, having stolen of the nectar of immortality, was caught and beheaded before he swallowed the divine stuff. The head thus became immortal, and ever afterward followed the sun and moon. When it occasionally caught them an eclipse resulted.

RAHWAY, rā'wā, N. J., city, in Union County; on the Rahway River, and on the Pennsylvania Railroad, about 20 miles southwest of New York City. It is a residential city, and its clean, well-laid-out streets, its parks and fine residences make it an attractive suburb. It has considerable manufacturing interests; the chief establishments are chemical works, printing houses, shirt factories, lace curtain factories, felt mills, steel works, carriage and music-box factories. There is a large trade in manufactured articles, fruit and vegetables. It has a high school, public and parish schools and a library, which has about 20,000 volumes. The old Revolutionary name of the locality was Spanktown, and in January 1777 a skirmish took place, noted in some histories as the battle of Spanktown. Pop. 9,337.

RAI BARELI, rī bā-rā'le, India, (1) principal city of a district of the same name, on the banks of the Sai, 48 miles southeast of Lucknow. It has a spacious fort, a magnificent pal-

ace, four fine mosques and the tomb of Nawab Jahan Khān. Pop. 18,798. (2) The division of Rai Bareli is now part of the united provinces of Oudh and Agra, and has an area of 1,751 square miles. Pop. about 1,100,000.

RAI SANYO, rī sām'yō, Japanese historian: b. 1780; d. 1833. He spent 20 years in preparing his 'Nihon Gwaishi' ('History of Japan Outside the Court'), which was published in 22 volumes in 1827. It is a compilation gathered from a vast number of Chinese and Japanese works of history and covers the history of the Shogunate from its origin in the 12th century down to the setting up of the Tokugawa dynasty in the early 17th century. A second work, 'Nihon Seihī,' in 16 volumes, was published in 1837, after Rai Sanyo's death. From a literary standpoint his works are of little interest, no attempt being made at anything more than a dry chronological record of events. Their political effect, however, was of inestimable importance. Strongly imperialistic in sentiment the presentment of the nation's history before the usurpations of military feudalism was used with tremendous effect in re-establishing the power of the throne. The first five volumes of 'Nihon Gwaishi' were translated by Sir Ernest Satow (1872). Consult Aston, W. G., 'History of Japanese Literature' (1899).

RAIATEA, rī-ā-tā'ā, Polynesia, an island of the Society group, northwest of Tahiti; area, 75 square miles. It is mountainous (3,400 feet), but fertile, and traversed by many streams. The chief products are cotton and copra. Pop. (Protestant) 2,300.

RAIBOLINI, rī-bō-lē'nē, Francesco. See FRANCIA, FRANCESCO.

RAID OF RUTHVEN, a mysterious event in Scottish history, which took place in August 1600. John Ruthven, Earl of Gowrie, and his brother, Alexander, then resided on the former's estate at Perth. The earl was bitter against James VI (later James I of England) who had put the earl's father to death for treason and who was in Ruthven's debt for a large sum. On 5 Aug. 1600, the king with a few attendants visited Ruthven's residence in order, as Alexander alleged, to confer with the earl in regard to the debt. After dinner the Ruthvens contrived to separate the king and his attendants, bringing the former into a private study and taking the latter into the garden. The guests were soon informed that the king had ridden off and the earl left them for a moment and soon returned and confirmed the report. While the guests were puzzling over the circumstance, they heard the king shouting "Treason!" from the study window. Suspecting a plot four of them rushed to the study where they found Alexander Ruthven struggling with the king. They killed Alexander, after which the earl and his servant, Cranston, rushed upon them and fought desperately to avenge his brother. However, he was overpowered and killed. In the study the king had found a man in armor, who, it was later said, was Henderson, chamberlain of the earl. As Henderson had offered no violence to the king he was pardoned. Three of the servants were hanged for their part in the conspiracy, the Ruthven estates were confiscated and the castle, in which the attack took place, was destroyed. Considerable mystery surrounds the strange event. The suggestion

has been made that Queen Elizabeth, who may have wished to secure the king's person and to rule Scotland in his name, used the Ruthvens as tools to accomplish this end. Others have suggested that there may have been no plot—merely a quarrel over the debt which led to the death of the Ruthvens, after which the king concocted the story of the plot to hide his own guilt. Consult 'Register of the Privy Council of Scotland' (VI); Barbé, 'Tragedy of Gowrie House' (Paisley 1887); Lang, 'James VI and the Gowrie Mystery' (London 1902); 'History of Scotland' (Vol. II, Edinburgh 1902); Burton, 'History of Scotland' (ib. 1867-70); Brown, Hume, 'History of Scotland' (Vol. II, Cambridge 1909).

RAID, in international law, an unauthorized invasion by an armed force of the territory of a state not at war. A raid must be carefully distinguished from an invasion, for in the latter either regular forces of a foreign state or regular forces of a body exercising its powers by delegation of that state must be guilty of the overt act. If so, it constitutes an act of war, whereas a raid, being unauthorized and unrecognized by any state, is not an act of war. The punishment of the offenders, if captured, is, therefore, very different. In case of invasion, they are treated as prisoners of war, but in case of a raid the offenders, if captured, are subject to the local law. The state invaded may compel compensation from the offending state or may retaliate by similar acts or by declaring war, but this is not true in the event of a raid.

Among the most famous of raids was that of Dr. Jameson (q.v.) who forcibly entered the Transvaal in 1895 at the head of an armed force of 600 men, and was one of the causes of the war that followed between the republic and Great Britain. Dr. Jameson's force was captured by the Boers and turned over to the British for punishment.

Among other raids may be mentioned those claimed to have been instigated by General Villa, head of the Mexican rebel forces, in the spring and summer of 1916, into territory in the southwestern part of the United States.

RAIFFEISEN, rīf'i-zēn, Friedrich Wilhelm, German economist, famed as the father of the peoples' banks: b. Hamm, near Coblenz, Germany, 30 March 1818; d. 11 March 1888. He entered the army in 1835, but was compelled by ill health to withdraw and then entered the civil service. During the agricultural troubles of 1846-47 he perceived the difficulty with which the small landholder procured credit and he conceived the idea of establishing small mutual credit associations which freed the farmer from the exorbitant rates of the usurers. His first efforts were at Heddersdorf and Wyerbusch and he then proceeded to extend the operation of the plan throughout Germany. In 1866 he broke down from overwork and retired for a time from public service. In 1878 he founded the "Landwirtschaftliches Genossenschaftsblatt" at Neuwied. He lived to see his plan in successful operation in Germany, Austria, Switzerland and Italy. He wrote 'Instruktion zur Geschäfts- und Buchführung der Darlehnskassenvereine' (1869); 'Kurze Anleitung zur Gründung von Darlehnskassenvereinen' (1888), etc.

RAIKES, rāks, Robert, English founder of Sunday schools: b. Gloucester, England, 14 Sept. 1735; d. there, 5 April 1811. He succeeded to his father's business as editor and publisher of the *Gloucester Journal* in 1757 and used its influence in exposing certain prison abuses in his native town. In 1781 he founded several Sunday schools which he engaged needy women to teach at a shilling a day, and succeeded in inducing the attendance of the children of the city. In 1803, largely through his efforts, the Sunday School Union was founded. Consult *Lives by Gregory* (1877), and *Eastman* (1880); Harris, 'Robert Raikes: The Man and his Work' (1899). RAILROAD AND OTHER LAND GRANTS. Grants for railroad and other purposes were the subject of vigorous discussion from an early period of our history, many holding that the Federal government had no authority to grant subsidies for internal improvements. The decision reached was in favor of such subsidies. The first of the kind was made 30 April 1802 in the Enabling Act of the State of Ohio which provided that one-twentieth of the net proceeds of the sales of public lands in said State should be given to the State for constructing public roads. Grants of land in aid of the construction of canals were authorized in later years. The first aid for the construction of a railroad was 2 March 1833 when the State of Illinois was permitted by Congress to divert its canal land grant of 2 March 1827 for the construction of a railroad, but this grant did not become effective. The first definite grant of lands to aid in the construction of a railroad was the Act of 20 Sept. 1850 to the State of Illinois. A number of grants of lands to States followed as aids to railroads.

After 1850 and the admission of the State of California into the Union a strong agitation developed for the construction of a railroad to the Pacific Coast which resulted in the acts of 1 July 1862 making grants of lands to the Union Pacific Railroad Company, the Central Pacific Railroad Company and other roads. There were many subsequent land grants to railroads up to 1871.

The land grants to the States and railroads for railroad purposes provided usually for a grant of the odd sections within 6 to 10 miles on either side of the line of road. In some cases the grant was 20 miles in width on either side. In addition the roads were authorized to select indemnity lands where any portion of the main grant had been otherwise disposed of.

The total area granted to States for canal purposes was 4,597,804.37 acres. The total area patented for wagon roads under their grants as reported to 30 June 1918 was 3,242,173.75 acres. For the same date the area patented to States for railroad grants was 37,784,852.58 and for

the same date to railroads was 85,927,123.63. The total area thus disposed of for public improvements to 30 June 1918 was 131,551,954.33 acres.

In addition to this, the granting acts authorized the issue of United States 6 per cent bonds in aid of the construction of the Pacific railroads on the basis of \$16,000 per mile in the Great Plains east of the Rocky Mountains; \$48,000 per mile for the portion crossing the Rocky Mountains; \$32,000 per mile for the line through the Central Plains with similar grants to the Central Pacific for the western part of the line. These bonds of the United States were a second lien against the property of the companies.

The total bond issue for the Pacific roads was \$64,623,512. All have made settlement except the Central Branch of the Union Pacific, which still owes the principal of the bonds, \$1,600,000, and interest which amounted to \$1,977,000 to 31 March 1919. This debt is being very slowly reduced by credits on account of the transportation of public property.

RAILS AND RAIL SHOOTING. Any birds belonging to the typical genera of the family *Rallidae* are popularly called rails, probably in reference to their harsh rattling cries, but the name is more particularly applied to certain species, other being known as marsh hens, crakes, etc. The family is included in the order *Gallae* or *Gruiformes*. The family is a large one composed of numerous species of moderately sized birds of generalized structure, found in most parts of the world. The body is compressed, the legs strong, the feet very large with long toes, which are lobately webbed in the coots, the wings and tail very short, the bill strong and variously shaped, but never greatly elongated nor provided with a sensitive tip, and the colors are usually obscure and sober. About 35 genera and 180 species of *Rallidae* have been recognized, but authorities differ concerning the retention of some of the more aberrant forms within the family. Three subfamilies are represented in the North American fauna: the *Fulicinae*, or coots, with lobate marginal webs on the toes and a horny frontal shield; the *Gallinulinae*, or gallinules, with a frontal shield, simple toes and usually richly-colored plumage, and the *Rallinae*, or typical rails, in which the family characteristics are best displayed and there is no frontal shield nor any webbing on the toes.

Most of the rails are marsh-loving birds, their long toes admirably serving to support them on the soft mud and their narrow compressed bodies facilitating movements among the stems of grasses and reeds. Owing to their stalking and largely nocturnal habits they are difficult to observe and, except by gunners, their abundance is not generally known. They run well and to escape danger trust to their ability

to slip quietly into a place of concealment. They seldom fly and, owing to the shortness of the wings, only in a weak, uncertain manner, but nevertheless some of the species perform extensive migrations. In feeding they are chiefly carnivorous, but never probe the mud for worms, etc., in the fashion of snipes, nor strain it as do the ducks. The nest is usually a rude bulky platform of dried rushes, etc., slightly elevated above the wet ground and the numerous eggs are thickly spotted. The young are fully downy and are said not only to run but to swim well as soon as hatched.

Besides the corncrake (*Crex crex*), which occasionally wanders from Europe to our shores, 12 species of true rails occur within the boundaries of North America. They belong to two genera. The king rail (*Rallus elegans*) or fresh-water marsh-hen is our largest species, reaching a length of 18 inches and a wing expanse of two feet. It is known by the rich cinnamon and chestnut hues of the under parts and the strong streaking of the plumage above. This species is abundant in the fresh-water marshes of the eastern United States but, although occasionally seen in New England, is rather southerly. Except for its habitat and the character of its food, which consists largely of aquatic insects, leeches and wild rice in season, the habits of the king rail closely resemble those of the next species. In the salt-water marshes from Connecticut southward along the Atlantic and Gulf coasts the king rail is replaced by the well-known clapper rail or salt-water marsh-hen (*Rallus crepitans*), which is extremely abundant from New Jersey southward and is resident in the southern half of its range, but migratory northward. It inhabits the reed-covered marshes intersected by ditches and creeks which border so much of our coast within the beach line and its presence is especially evident during the breeding season when the loud clattering cry is heard incessantly both by day and night. All kinds of snails, crustaceans and worms inhabiting such regions constitute its food. The nest is a heap of dried reeds and grasses elevated just above the water by the side of a ditch and usually concealed by an artful overarching of reeds. As many as a dozen, but more frequently about eight eggs, are laid; they are oval, of a cream or buff color and thickly blotched with brown and lavender tints. The clapper rail is slightly inferior to the king rail in size and is of a blended grayish color tone, rather than a streaked red. Closely related species are the *R. obsoletus* of California and *R. scottii* of Florida. The Virginia rail (*R. virginianus*) is about 9 or 10 inches long and in color a perfect miniature of the king rail. Unlike the latter it inhabits salt and tide-water as well as inland marshes and is very widely distributed throughout temperate North America and southward. It is a regular migrant, in most of the Northern States and Canada remaining from April to September to breed. Although generally common, they are best known by their nocturnal and diurnal cries. In nesting and other habits they resemble the clapper rails, but the eggs are of course much smaller. The Carolina or sora rail or crake and the yellow rail belong to the genus *Porzana*, which differs from *Rallus* in having the bill short and stout instead of long and slender.

The former (*P. carolina*) is eight or nine inches long, brownish above and unspotted below, the latter (*P. noveboracensis*) is only about six inches long, with much yellow above and the breast spotted. Both appear to range widely in North America, but the former is everywhere a far more abundant bird. The sora, also erroneously called ortolan, is the best known and during the migrations the most plentiful of the rails in all suitable reedy marshes along the shores of lakes and rivers, and it breeds in similar localities in the Middle States and northward. A third related species, the black rail (*P. jamaicensis*), is rarely taken. The North American rails are all marsh birds, but the European corncrake prefer the cultivated fields, and in New Zealand and other Southern islands many remarkable forms of field rails and some curious flightless and burrowing species are found.

Rail-shooting in the autumn, when they, and particularly the Carolina rail, congregate in immense numbers in the river swamps, has many followers; but it can hardly be called a sport, being nearly on a par with the annual slaughter of reed birds which occurs at the same time and places. The method is very simple. Each gunner has an assistant who poles him about in a flat-bottomed boat or skiff through the creeks and passages which everywhere intersect the swamps. Usually this is done at high tide, owing to the shallowness of the creeks at other times and because the rising water restricts the area on which the birds can run. Sometimes spaniels or other dogs are employed to drive the birds, but this is unnecessary, as they are easily seen as they run along the banks of the creeks or rise in short labored flight. Enormous numbers, often running into the hundreds, may be secured by a skilful shot who has mastered the problem of shooting from an unsteady boat. During the gunning season the sora feeds largely on the seeds of reeds and wild grains, becomes very fat and is a truly delicate morsel. The other species are also sought but to a less extent. At times of unusually high tides great numbers of clapper rails are killed along the New Jersey coast as they huddle bewildered on little islands and masses of reeds in the flooded salt meadows. Immense numbers of the eggs of the same species are also gathered for food. Consult Baird, Brewer and Ridgway, 'North American Water Birds' (Boston 1884), and Roosevelt, 'Game Water Birds' (New York, 1884); Newton, 'Dictionary of Birds' (New York 1896); Evans, A. H., 'Birds' (in 'Cambridge Natural History,' Vol. IX, ib. 1900); Job, H. K., 'Among the Water-Fowl' (ib. 1902) and Bulletin 128 of the United States Department of Agriculture (Washington 1914).

RAILS AND STRUCTURAL SHAPES.

Manufacture of. One of the most important branches of the iron and steel industry is the manufacture of rails. Up to about 1855, all rails were made of wrought iron. In England beginning about 1767, various forms of cast-iron and wrought-iron rails were employed, the first being a grooved rail for tramway purposes, which was subsequently developed into the regular railway by the use of cast-iron flanged rails. The first wrought-iron rail was patented in England by Birkenshaw, in 1820, and on ac-

count of its peculiar form was known as the "fish-belly" rail. It was the first to be rolled in continuous lengths embracing several spans and was laid in cast-iron chairs spiked to stone blocks set at intervals of three feet. It weighed about 33 pounds per linear yard. Its manufacture by the rolling process, however, was quite difficult, and it was superseded by the "flat-foot"

FIG. 1.—Tramway rail.

count of its peculiar form was known as the "fish-belly" rail. It was the first to be rolled in continuous lengths embracing several spans and was laid in cast-iron chairs spiked to stone blocks set at intervals of three feet. It weighed about 33 pounds per linear yard. Its manufacture by the rolling process, however, was quite difficult, and it was superseded by the "flat-foot" rail which combined a solid head with a flanged base and was laid by being fastened to timber sleepers or ties by spikes driven through the holes in the flange. The flat-foot rail was followed by the bridge-rail, the double-headed rail and the bull-headed rail. The last named, although involving a great waste of metal, owing to the excessive thickness of the web, is used exclusively in England, while in the United States and almost all foreign countries the rail of the flanged T-section is universally employed. It was invented by Col. R. L. Stevens, in 1830, but the form in use in America is a modification suggested by the special committee appointed by the American Society of Civil Engineers, in 1893; while the form used in Europe is that invented by Sandberg. It is usually made in lengths of 30 feet, but rails as long as 60 feet are used to some extent. In weight it varies from 25 to 100 pounds per linear yard, according to the amount of traffic, the speed of transportation and the gradients and curves of the roads upon which it is used.

FIG. 2.—Fish-belly rail. (a) Section. (b) Side view.

About 1865, a few years following the discovery of the method of manufacturing Bessemer steel, rails of that material were experimentally rolled in the United States and soon began to supplant those of wrought iron. At the present time all rails are made of steel, and they have, probably, contributed more toward the rapid development of this country than any other

single product of the steel industry. The raw materials consist of iron-ore, coke and limestone, mixed in proportion as follows—ore two pounds, coke one pound and limestone one and one-third pound. Two fundamental processes of manufacture are employed—the reduction of the ore in the blast furnaces and the conversion of the molten metal into steel in the converter, followed by the operations of

FIG. 3.—Flat-foot rail.

the rolling mill. (See IRON AND STEEL INDUSTRY IN THE UNITED STATES). The Bessemer process of conversion is generally employed on account of its rapidity as compared with the open-hearth process, taken in connection with its capability to produce a grade of metal of a quality sufficiently high to satisfy the general specifications for rails. In the manufacture of steel rails, the work of smelting the iron in the blast furnaces is continued day and night, year in and year out, without intermission, but the converters and the rolling mills are generally shut down from 1.30 P.M., Saturdays, to 5 P.M., Sundays. During the intervening times, the product of the blast furnaces, instead of being poured into the mixers (by which the

FIG. 4.—Bridge rail.

casts obtained from the different blast furnaces at varying temperatures and qualities are reduced to a common temperature and quality), are run into the pig-casting machine which consists of a series of parallel endless chains of molds arranged to pass in front of the pouring mouth of the ladle. The molds receive the metal at the lower end of the chain and deliver the casts at the upper end of the chain, where they are loaded upon railway cars for shipment.

In the regular work, as soon as the ingot cast from the metal purified in the converters, is set, the mold is drawn from it by a hydraulic stripper and it is raised by an overhead electric crane and then lowered into the soaking pit,

FIG. 5.—Double-headed rail.

where it is brought to the proper temperature (white heat) for rolling. It is then taken to the blooming mill and passed through the blooms (rollers) seven times and reduced to a section varying in size according to the size of the desired rail. The section of the ordinary rail used on the railroads is nine and one-fourth inches square, and the ingot when rolled to that section attains a length of about 15 feet.

It is then sheared into two or three lengths, as the case may be. These pieces called blooms are carried to the rail mill, which consists of three sets of rollers—the roughing rolls, the intermediate rolls and the finishing rolls, through which the bloom is passed successively. Through the first set it is passed five times and reduced approximately to the section of the desired rail. It is then, without being reheated, passed five times through the intermediate rolls and reduced more closely to the desired shape. If the rail is of the lighter variety, weighing from 50 to 70 pounds per linear yard, it is then passed through the last set of rolls and finished on a single heat, with satisfactory results. But if the rail is of the heavier class, ranging in weight from 80 to 120 pounds per linear yard, its tendency to retain heat longer, and, therefore, be passed through the finishing rolls at a

FIG. 6.—Bull-headed rail.

temperature too high to give good results, is overcome by allowing it to remain upon a cooling table for an interval of time ranging from 45 to 90 seconds, and it is then passed through the finishing rolls at a lower temperature, thus giving a rail of a much better quality of metal, especially in the head of the rail. The rail is now sawed into the desired lengths, usually of 30 feet, and then passed through the cambering rolls, where it receives sufficient camber to prevent warping when it is being cooled. After being cooled off on the hot beds it is straight-

ened, chipped and filed and is then ready for shipment as a finished product. Improved apparatus has in recent years greatly facilitated the operations in rolling rails. Electricity has been a prime factor in their operations.

In the manufacture of "structural" shapes (a term which includes a great variety of angle-irons, T-irons, I-beams, Z-bars, eye-bars, channel-irons and built-up posts, beams and girders), used in the construction of modern buildings and bridges, the shapes are rolled from basic open-hearth steel of three grades—the rivet steel with an ultimate strength ranging from 48,000 to 58,000 pounds; the soft steel from 52,000 to 62,000 pounds; and the medium steel from 60,000 to 70,000 pounds. The elastic limit generally required is not less than one-

half of the ultimate strength, and the test pieces are required to be capable of being bent over through an angle of 180 degrees, without fracture. The raw materials, consisting of ore and pig-iron, are melted down in the cupolas and are then run into the open-hearth tilting furnace, where an equal amount of cold scrap, in the form of steel junk, crop-ends, punchings, etc., from the construction shops, is added. The contents of this furnace, sometimes amounting to 75 tons, are poured into a hydraulic ladle crane, which is then swung over the casting pit, and the molten metal poured into the ingot molds in the usual way through the bottom of the ladle. The ingots when set are reheated in the soaking pit and then passed through the blooming mill and reduced to blooms and billets of any required size. They are then rolled

ited to not more than 10,000 pounds below the test specimen of the grade of steel from which they are rolled. The eye-bar heads are formed by upsetting machines operated by hydraulic power, in which the heated end of the eye-bar is pressed to the desired circular form by the three-fold die of a hydraulic press, in a single operation. The head is then forged and punched at one heat, and then finished bored. Eye-bars are tested in a hydraulic testing machine capable of exerting a maximum pull of 700 tons. When an order of eye-bars is completed, one of the bars is pulled asunder in the machine. In general, they are required to show not less than 10 per cent elongation in the body of the bar and they must break in the body and not in the eye. See BUILDING IN THE UNITED STATES; ELECTROCHEMICAL INDUSTRIES; IRON; IRON,

FIG. 8.— Rail passing through the intermediate rolls in the rail mill.

to the desired shapes, sawed into the required lengths and then cooled on the hot beds. From the hot beds they are passed through the straightening rolls, and after being cut into exact lengths, as required, they are ready for the construction shop.

In the production of finished bridge members, the shapes are carefully laid out by wooden templates, in which the precise positions of rivets, angles, gussets, etc., are marked. The operation of building up requires great care and accuracy. The shapes are sawed or sheared to exact length and the sides and ends faced and planed down as required by the drawings. The small holes for bolts and rivets are punched by lighter forms of machinery driven by electric power; on the other hand, all pin-holes are first punched and then bored to exact diameter. In assembling, the rivet holes are properly registered, being reamed if necessary, and the separate parts bolted together and finally riveted up by hydraulic or pneumatic riveters. See METAL-WORKING MACHINERY.

In the manufacture of eye-bars, used in bridge construction, the tensile strength is lim-

RAILWAY CARS. *Passenger and Freight.*— Passenger cars on the earliest railways usually had small bodies of the stage-coach type mounted on four-wheel frames. In 1833, however, cars long enough to seat 60 passengers and having the body carried by a pair of four-wheeled swiveling trucks were designed and built by Ross Winans for the Baltimore and Ohio Railroad. Cars approximating the present American type were in use as early as 1835. Distinctive features of this type are the long body mounted on four-wheel or six-wheel trucks and having cross-seats on both sides and a central aisle which, with end doors and

forms, permits of passage through the train. A modified design has pairs of fixed chairs in place of the usual double seats. As the chair backs may be lowered for reclining more space is required and a 70-foot car may have seats for 84 or chairs for 64 passengers. Vestibules enclosing the car platforms and connected by flexible diaphragms were introduced in 1886, but similar connections between mail cars had been used since 1852. They add to the safety and convenience of passengers and decrease danger in collision since they make the train practically one long articulated car.

A long-distance train may have day cars (often called coaches), mail, express and baggage cars, parlor or sleeping cars, a dining car and perhaps an observation car with library and writing desks, while bathrooms and barber and stenographer service are sometimes included. American railways are noted for going rather to extremes in providing comforts and conveniences for passengers, although this greatly increases the weight of car in proportion to the passengers carried. The American type of car is extensively used abroad, except in Europe where the existence of from two to four classes of passengers makes its application difficult.

European railways have always used cars of the compartment type, with transverse partitions and side doors. Each compartment has two opposite seats, so that half the passengers must ride backward. The cars are in general smaller and lighter than those of American railways and many have only four to six wheels, but of late years the size and weight have been increased. Trucks which are called "bogies" were introduced on English cars in 1872. Corridor cars, an innovation of about 1883, have a narrow passage along one side, with side doors to the compartments and end doors to vestibules between the cars. A 43-foot 18-ton compartment car will seat 70 third-class passengers in seven compartments, or a 50-foot car may seat 80, while a 54-foot 23-ton car may carry 18 first-class and 40 third-class passengers. A 50-foot corridor car, however, may seat only 36. Special suburban cars for workmen carry 120 passengers in 10 compartments.

Car equipment of American railways amounted to 1,216,000 cars of all kinds in 1891 and 2,600,000 in 1916. Of the latter, 56,000 were for passenger trains, 2,400,000 for freight trains and 100,000 for railway service. Passenger equipment included 40,000 day cars, 1,380 dining, 660 parlor, 750 sleeping, 1,600 mail and 10,000 baggage and express cars. These are exclusive of the Pullman Company's 7,750 sleeping, parlor, tourist, dining and observation cars. Private cars, officer's cars and hospital cars are special equipment. Cars having their own motive power—steam or gasoline—are used sometimes on lines of light traffic. Freight cars included 1,050,000 box cars, 150,000 flat and gondola, 920,000 coal, 53,000 refrigerator, 88,000 stock and 10,000 tank cars, besides 95,000 caboose cars for the train crews.

Modern day cars 68 to 78 feet long over platforms seat from 60 to 90 passengers and weigh from 50 to 72 tons. A steel mail car was put in service in 1889 and a few experimental cars were built later, but in 1907 the Pennsylvania Railroad adopted steel construction for all its passenger cars. Other railroads

followed and in 1908 there were 1,228 steel cars, 75 per cent of which were for suburban or rapid-transit service. In 1916 about 22 per cent of the passenger equipment was of steel, exclusive of cars having steel underframes and wood bodies. Steel 80-foot day cars for 88 passengers weigh about 56 tons; 76-foot mail car, 64 tons; 72-foot dining car, 70 tons; 80½-foot sleeping car, 65 tons; and 64¼-foot suburban car for 72 passengers, 37 tons. While heavier than wooden cars they have advantages in safety, durability, maintenance and repair.

Sleeping cars were run between Philadelphia and Harrisburg on the Cumberland Valley Railroad in 1836. These had three tiers of fixed berths on one side. In 1856 T. L. Woodruff built and patented a sleeping car embodying some features of the present type. A similar design was patented by Webster Wagner in 1857. The more successful work of George M. Pullman began in 1859 when he converted two 42-foot day cars into 10-section sleeping cars for the Chicago and Alton Railroad. These were the first made with folding berths. His first car of the present type was built in 1864. The Mann car, with separate compartments opening from a side corridor, was put in service in Europe in 1873 and in the United States in 1883. The Pullman Company was organized in 1867 and eventually acquired control of competing concerns. Its standard car has at night two double rows of longitudinal berths shut off from the central aisle by curtains. While strength and appearance have been improved, the cars still have primitive arrangements for dressing and toilet facilities. Compartment sleeping cars, which are used only to a limited extent, have greater privacy and convenience but carry fewer passengers. It is this type which is mainly employed in Europe, generally with berths across the car and sometimes without upper berths. For long runs, Pullman in 1867 introduced the hotel car, which was a sleeping car provided with a kitchen, meals being served on portable tables fitted between the seats. This was soon superseded by the separate dining car.

Freight cars have been developed to great size and capacity by American railways owing to the long distances, the large amount of bulk freight such as coal and ore and the economy of large loads, since car weight per ton of load decreases as the load increases. Thus large cars and long trains are among the factors in the marked economy of railway freight transportation in the United States. The 10 and 15-ton car capacity of 1875 increased to 20 or 25 tons by 1885, when 30-ton cars also were being used. Few cars of less than 30 tons capacity are now in use; 40 and 50-ton cars are common and there are numbers of 60 to 100-ton cars.

The maximum is reached in 120-ton steel coal cars on two or three railways. These are 50 feet long, have six-wheel trucks and weigh 37 tons. Other railways have 48-foot coal cars of 85 tons capacity weighing 30 tons. Steel construction for open cars and steel underframes for other types of freight cars are used very extensively. A 40-foot box car of 50 tons carrying capacity will weigh about 24 tons; 45-ton refrigerator car, 30 tons; 100-ton gondola, 30 tons. Refrigerator cars for meat, fish, fruit, etc., have thick walls, roof and floor, in-

sulated by air spaces and packing and are fitted with ice chests. Similar cars, without ice, serve in winter to protect perishable freight, being sometimes warmed by a small stove beneath the floor.

Special classes of freight cars include coke, coal, dump, flat, horse, stock, ore, poultry, refrigerator and tank cars. The ordinary length of car is 30 to 42 feet. Long cars with three trucks have been built; also steel-frame cars with four or more trucks for carrying guns or very large and heavy castings.

European freight cars are in general much smaller and lighter than those of American railroads. Four-wheel cars 10 to 15 feet long, of 8 to 10 tons carrying capacity and 6 to 8 tons weight, form the bulk of the equipment. There are six-wheeled cars of somewhat greater size and up to 20 tons capacity; also some 30 to 40-ton cars on four-wheel trucks. Closed or box cars are used less than in America, freight in open cars being protected by tarpaulin covers furnished by the railways. These small cars are suitable and economical for the system of prompt handling of small shipments which is characteristic of European—and particularly English—railway service. They are not economical for coal and other bulk freight, but though larger cars have been introduced the use of varying lengths of cars causes complications at terminals, coal docks and mines. The American types of long freight cars on trucks are used extensively in India, South America, Australia and Africa; also in Europe, outside of England.

Cast-iron wheels are a feature of American cars and long experience in manufacture has led to the production of a grade of metal peculiarly adapted to this service. Steel and steel-tired wheels are used extensively, especially under passenger cars. For noiselessness, compressed paper centres in steel tires have been tried. Wood-centre wheels for passenger cars and wrought-iron wheels for freight cars are used in England and are generally larger than the 33-inch or 36-inch wheels common in American cars.

Automatic couplers for cars are used universally in the United States. For the old link-and-pin coupler the drawbar of each car had an enlarged hollow head to receive one end of a straight link, which was secured by a pin dropped through a hole in the drawbar head. Removal of the pin released the coupling. Owing to the deaths and injuries resulting from coupling and uncoupling by hand, a campaign for compulsory use of automatic or safety couplers was started by L. S. Coffin, resulting in the passage of a law by Congress, in February 1893, providing that by 1898 all freight cars must be equipped with automatic couplers that would couple by impact and would not require men to go between the cars. The time was later extended and the application of these and other safety appliances was put under the jurisdiction of the Interstate Commerce Commission.

Automatic couplers had been the source of innumerable patents and extensive trial, but the difficulty was to have all railways adopt and introduce one universal type. Designs patented by Eli H. Janney in 1873 and 1874 were modified in 1879 to the general contours of the present coupler heads. At first this was for pas-

senger cars but later it was adapted to freight cars. In 1884 the Master Car Builders' Association adopted the principle that the coupling faces should be in a vertical plane, or free to move vertically. In 1887 it adopted the Janney type as standard in order to arrive at some uniformity. The inventor broad-mindedly relinquished his claims to monopoly on the contours of the coupler heads, so that any manufacturers could make couplers of this standard type but with their own details as to drawbars, springs, etc. Much has been done to simplify and standardize the designs in order to eliminate the varying details.

In the Janney or M.C.B. coupler each drawbar has a deep claw-shaped head, to the claw of which is pivoted an L-shaped knuckle. When two cars are pushed together the knuckles interlock. To uncouple, a vertical locking pin is withdrawn from one coupler, the knuckle being able then to swing open and release the other when the cars are pulled apart. The lock is attached to a chain on a rod operated from the side of the car. Passenger cars now have this same coupling, but at one time there was extensive use of an automatic coupler invented by Ezra Miller in 1867. The drawbar had a fish-hook end, with inclined face; when two cars were pushed together these contact faces forced the drawbars sideways until the hooks interlocked. To uncouple, one drawbar was pulled sideways by a lever on the car platform.

Foreign railways make general use of coupling chains attached to hook-end drawbars, the free end of the chain on one car being hooked over the drawbar of the other car. The chain may be drawn tight by a right and left hand screw until spring buffers on the ends of the cars are in contact, but on freight trains the chains are often left loose. Automatic couplings have been tried but have not come into use, except a combined hook coupling and central buffer applied to narrow-gauge cars. This differs from the American type in that the coupling faces are horizontal and narrow, the hook in one coupling riding up to engage a slot in the other.

Railroad Car Lighting and Heating.—For lighting passenger cars, electricity and compressed oil gas have superseded oil lamps. Other illuminants tried are coal gas, acetylene gas and air saturated with gasoline vapor. Electric lighting is applied generally by equipping each car with a generator driven from one of the axles by a belt, storage batteries being used to maintain the light when the train is at rest or moving at slow speed. Another system is to supply the entire train from one generating plant placed in the baggage car and driven by a steam engine, though it may also be driven from a car axle. This system is more applicable for trains made up of the same cars for long distances.

Electric light for railway cars was introduced first in 1881 by the London, Brighton and South Coast Railway, of England, using cars equipped with storage batteries. The time (several hours) and inconvenience of charging the batteries led—in 1883—to the addition of a dynamo driven from the car axle. The battery system was first used in the United States in 1882 by the Pennsylvania Railroad, which applied it extensively. This was followed

by other railways, but the system was abandoned in a few years owing to the time required for charging the batteries, the cost of equipment for brilliant lighting and the cost of maintenance due to the short life of the batteries. As the batteries for one car weighed about a ton, to change them would have been about as much trouble as to charge them.

Direct-dynamo lighting, with a generating plant to serve the entire train was introduced in 1882 on the Paris, Lyons and Mediterranean Railway, and in 1889 on the Chicago, Milwaukee and Saint Paul Railway. This was supplemented later by batteries, either on each car or on the car with the plant, in which latter case some auxiliary light had to be supplied for use when the cars were separated.

Car heating on American railways is effected almost universally by piping steam from the locomotive to coils and radiators, the cars being connected by flexible hose. Coal stoves caused so many disasters that their use has been prohibited. A special heater for sleeping and dining cars which may have to be separated from trains consists of a small and well protected stove with boiler connected to the heater pipes. At large terminals the tracks on which passenger cars are stored are equipped with steam pipes with flexible connections for the car-heating systems. In Europe this system is used less extensively. In England the main reliance is upon portable "foot warmers" filled with hot water or with acetate of soda, which latter retains heat for a period of several hours. For railroad car braking see **AM BRAKE**; for construction and repair machinery see **RAILWAY SHOPS AND MACHINERY**.

Associate Member American Society of Civil Engineers.

RAILWAY CONSOLIDATION. The consolidation—or as the English say, the amalgamation—of railways consists either (a) in uniting connecting lines into one continuous line, or (b) in uniting parallel or competing lines into a system. Railways in the United States were originally built for the most part in short, disassociated lines—little stretches of road from A town to B town. Construction had progressed only a little before the desirability of connection between these lines became obvious. And almost at once such connection began to be arranged, so that, in the progress of our railway building and some time prior to about 1870, a great number of these little lines in every part of the country had been amalgamated, with the result of developing our great trunk line systems. Before we had entered upon the last quarter of the 19th century, it had come to pass, speaking generally, as a result of this tendency to unite connecting lines, that very much the greater and more important part of our railway system consisted of long lines of road under a single management or control, made up, especially in the older parts of the country, of a less or greater number of formerly disconnected and independent local lines, which had been one after the other taken over and incorporated into the greater continuous line or system. Almost all the valuable and well located local lines had, 30 years or more ago, thus been absorbed into larger and less local combinations. Such consolidation, working only benefit to the public and demonstrating its

usefulness as it went along, provoked only a small amount of opposition, and these amalgamations of connecting lines usually secured legal sanction, whenever necessary, without the protest of the politicians. But about 1870—now (1917) about a half century ago—a tendency in the direction of the consolidation of parallel and competing lines developed. What had long been known in Europe to be the true law of railway construction and the sound basis upon which railways must ultimately come to exist and be operated in every country where there is enough wealth and commercial activity to make them successful—namely a division of territory and the practical elimination of competition between parallel lines in the same territory—began to assert itself and to be felt to be applicable here; and directly we entered upon a period of consolidation, not now of connecting but of competing lines; and, summing up the whole matter in a single sentence, that process of amalgamation, having now gone on in this country for nearly 50 years, it results that we are now at the end, substantially, of the second stage of railway combination.

First, we built isolated and disconnected local lines; second, we united these connecting lines—whenever they did connect—into continuous lines; and third, we divided up the territory between theretofore competing lines, by gradually amalgamating either the ownership or the control of such lines in a defined territory, thus securing little by little to a single interest, a territorial monopoly of the carrying services of the locality. This process carried out to its logical conclusion roughly divides the whole country into railway territories of greater or less extent, within each of which one single railway system is paramount or absolutely controlling. This readjustment of ownership and control between the greater railway companies of the country goes steadily on. In some sections of the country it seems to have been fully and finally accomplished; in other sections it is in progress; and only where the game isn't worth the candle or where the work has been done, is there an absence of activity in this direction, the tendency so to consolidate, first connecting and then competing lines, has been universal and inevitable, and such consolidation is in the one case an accomplished fact and in the other an irresistible evolution. Very little effort was made to prevent the earlier consolidations, that of merely connecting lines. It is now well understood that such efforts, if they had been made, would have failed, and it is now not questioned that such consolidations have been beneficial both to the public and the railways. On the other hand a very great deal of effort has been made by courts and statutes to prevent and hinder the second form of consolidation, that of competing or parallel lines. These efforts have also for the most part failed, and it is now coming more and more to be believed that they will ultimately wholly fail to prevent what seems to be the inevitable in railway development. Moreover in the case of the amalgamation of connecting lines, the mischiefs which have been apprehended have generally not been realized; so that now not only most practical railway men, but many students of the railway problem believe that in the outcome the balance of benefit both to the carrier and to the public will be also found on the side of terri-

torial division between competing lines. The emphasis of our intelligent thinking and our most efficient effort is now put rather on regulation than repression.

The history of railway construction and combination throughout the world seems to indicate *first*, that the consolidation of competing lines is inevitable; *second*, that efforts by legislation or litigation to prevent it always fail; and *third*, that such consolidations benefit both the public and the railways. The facts and figures concerning these consolidations in the United States are detailed elsewhere in this work, but the economic questions involved are still open ones with us. Elsewhere throughout the world these questions seem to be settled. Thus in England, where the railway problem has in many of its features been strikingly like our own, the question is now quite at rest. In France the question never really arose, and elsewhere in Europe it has been decided everywhere in favor of amalgamation and against the continuation of competition between lines serving the same territory. (The writer's argument in the Supreme Court of the United States, October Term, 1903, upon the appeal of The Northern Securities Company *et al.* v. the United States).

England.—In February 1872 a Select Joint Committee on Railway Companies' Amalgamation was appointed by the two houses of the English Parliament to investigate and report back the condition of the railways of Great Britain, particularly in respect of the consolidation of lines and the division of territory among the greater companies. Mr. Chichester Fortescue, in moving the appointment of the Select Committee in the House of Commons, on 23 Feb. 1872, said that "20 years ago a committee had reported against the system of amalgamation, but since that committee reported amalgamation had gone on as merrily as before—the fact being that 5,000 miles of railway had been added to the greater railways since that time."

This committee called a great number of witnesses and went fully into the details of the matter throughout the British Islands, and on 2 Aug. 1872, presented a voluminous report, from which it appeared that by the end of the year 1843, 71 separate and independent lines had been constructed, averaging about 30 miles each in length. During the following year the average mileage per independent line was reduced one-half, so that by the end of the year 1844 the average was only about 15 miles. Between 1844 and 1847, 637 separate companies had been chartered, with a total authorized length of about 9,400 miles of line. Eleven proposals, for example, were made to Parliament for lines of railway through a single narrow valley, where but one line was possible. This called so loudly for relief that consolidation began about 1847, and so proceeded, by the gradual absorption of the smaller lines by the larger systems, and by a consequent division of territory between the consolidated companies, that by 1872 it had come to pass that the railway business of the kingdom was substantially performed by no more than about six of these great amalgamated companies. The first English railway charters contained provisions intended to prevent competition both between the lines themselves and between them and the canals, es-

pecially in freight traffic. George Stephenson, the father of English railways, seems to have appreciated clearly the mischief to be avoided in the matter of competition, even at that early day, and he, therefore, set himself to the task of getting the railway system in that country started right in this particular. His view on this subject was summed up in his much-quoted saying that "where combination is possible, competition is impossible."

In 1836, a Mr. Morrison, M.P. from Inverness, made a remarkable speech in Parliament, in the course of a discussion of the then English railway situation, in which he pointed out with uttermost clearness that a railway must in the nature of things be a monopoly; that competing roads will inevitably combine; that parallel lines are sheer waste of capital and that fixed maximum rates are useless. This utterance is the more remarkable because it stated clearly at the outset of railway building and before there was any basis of fact and experience upon which to found such generalization, the ultimate principles which long experience has since demonstrated to be sound.

Thus it is seen that the English railways started right but that they soon got wrong, and for the first 30 years and more, blunders in plenty were made in futile endeavors to construct and operate railways on the principle of inter-competition. Uncounted treasure was wasted in these attempts, and absolutely nothing but experience was gained by it. By 1872 competition had been substantially eliminated through the operation of natural laws and in spite of hostile legislation and litigation. It was said in Parliament, in the debates over the appointment of the Select Committee in 1872, that there was not at that time a single competitive rate existing in the kingdom. With the legislation of 1873 the general railway situation in England was fixed and determined, and the agitation for competition ended. The railways ceased to be bugbears, and fears of mischief to the public from the growth of railway influence and power gave place to intelligent criticism of railway methods and to a public-spirited determination to get good service at fair rates while giving the companies a free hand to manage their finances in their own way. Thus, after nearly 40 years of experiment, agitation and disturbances, the English people came back about 1872 to their point of commencement. Mr. Adams, in his 'Railroads and Railroad Questions,' says that then England "settled down on the doctrine of *laissez faire*"; and President Hadley, in his 'Railroad Transportation,' says: "It might better be said that it has settled down on the policy of specific laws for specific troubles." By about 1872, as we thus see, the problem was solved by the operation of immutable economic laws, and the decision against competition between lines made beyond all possibility of reversion. To make a summary statement it appears that in 1847 there were about 5,000 miles of railway in England, owned and operated by several hundred independent and competing companies; 25 years later there were 13,000 miles of railway, owned and operated by 12 partly competing companies; in 1917 there were about 24,000 miles, owned and operated by about six non-competing companies.

The history of some of the greater English

companies taken a little in detail illustrates the situation. The London and North-Western Railway was first opened for traffic in 1837, about a month after the accession of Queen Victoria. In 1846 it consisted of a main line from London to Birmingham, with some insignificant branches. In 1852 a writer on the position of the company complains that it "fell a few years back into the error generally committed by railway companies of amalgamation with numerous other railway companies. From being a line from London to Birmingham, 112½ miles, it has become a line or lines of 539½ mile long—five times its original length." Since that time it has increased its mileage nearly fourfold, and has merged into its system the Chester and Holyhead lines on the west and the Lancashire and Carlisle on the north, besides numerous smaller undertakings too numerous to mention. The Great Western Railway has been absorbing smaller independent lines in its territory for many years, and altogether considerably more than 100 have been so absorbed within the last 40 years. Since 1896 it has taken over about 20 such lines, adding thereby 260 miles to its system. Of its total capital expenditure from 1892 to 1901, amounting to about £15,500,000, nearly £5,000,000 represented amalgamations. The North-Eastern Railway is a consolidation of various small lines which has resulted in a vast network of railway in the northeast of England without a single intruder in the territory in the shape of a competitor. The report of the Select Committee on Railway Amalgamation in 1872 contained the following reference to this line:

The case of the North-Eastern is a striking illustration. That railway or system of railways is composed of 37 lines, several of which formerly competed with each other. Before their amalgamation they had, generally speaking, high rates and fares, and low dividends. The system is now the most complete monopoly in the United Kingdom; from the Tyne to the Humber with one local exception, it has the county to itself, and it has the lowest fares, and the highest dividend of any large English railway. It has had little or no litigation with other companies. While complaints have been heard from Lancashire and Yorkshire, where there are so-called competing lines, no witness has appeared to complain of the North-Eastern; and the general feeling in the district it serves appears favorable to its management.

The Great Central Railway, which was opened for all classes of traffic in April 1899, has a total mileage of 665 miles. Of this mileage 465 belongs to it and 200 are jointly owned with other companies. In addition the company owns 111 miles of canals and tramways. It is, therefore, a system essentially made up of joint lines and canals. It is also the newest line in England and may stand for the most recent type of development in that country.

Working along essentially parallel lines all intramural transit in London which is wholly or partly underground, aggregating nearly 225 miles in length, has been in effect consolidated into two great substantially non-competing enterprises, dividing the territory in a way between them, upon a line (roughly speaking) which runs northwest and southeast through Piccadilly Circus, or dividing, along non-competitive lines as much as possible, about Piccadilly Circus and converging severally therein. The Joint Parliamentary Committee of 1901 reported that it was desirable that the working of underground railways in and around London should be put under the control of some one

consolidated interest; and that has been the ultimate solution.

The English courts commenced, about the middle of the last century, to break down the old common-law doctrines theretofore in vogue against monopolies, which were invoked in opposition to railway consolidation. Gradually the whole legal theory upon which those doctrines were attempted to be sustained has been overthrown, until now there is in England no legal objection possible to be urged, and very little popular prejudice to the amalgamation of railway lines whenever and wherever it seems to be economically desirable. The legal arguments against these consolidations were always drawn from the old decisions against monopolies and restraint of trade, which more than 50 years ago began to be repudiated *in toto* by the English judges. Thus in a leading case often referred to, which was decided in the House of Lords about 1850, Lord St. Leonards used the following notable language:

My Lords, there are just a few remarks that I wish to make upon public policy. I will not add a word to what has been already said by my noble and learned friends, but I will call your attention to what fell from one of the learned judges (Mr. Justice Cresswell) as regards the restraint of trade. That learned judge says that with regard to the restraint of trade, there is a maxim in common law, and he refers to a case in Year Books (2 Hen. V., pl. 26), to prove it; but the learned judge did not tell your lordships upon what that maxim was founded. Nobody supposes that there was any statute upon the subject in those times. Upon what, then, was that maxim founded? Why, upon public policy for the good of the realm. It was not good for the realm that men should be prevented from exercising their trades. Now, let us see what this particular case is; it lies in few words and remarkable consequences have resulted from it. It was an obligation with a condition that if a man did not exercise his craft of a dyer, within a certain town, that is, where he carried on his business, for six months, then the obligation was to be void, and it was averred that he had used his art there within the time limited, upon which Mr. Justice Hull, being uncommonly angry at such a violation of all law, said, according to the book, "Per Dieu, if he were here, to prison he should go until he made fine to the king, because he had dared to restrain the liberty of the subject." I wish to draw your lordships' attention to this case. Angry as the learned judge was at that infraction of the law, what has been the result of that very rule without any statute intervening? That the common law, as it is called, has adapted itself, upon grounds of public policy, to a totally different and limited rule that would guide us at this day, and the condition which was then so strongly denounced is just as good a condition now as any that was ever inserted in a contract, because a partial restraint, created in that way, with a particular object, is now perfectly legal. Without any exclamation of the judge, and without any danger of prison, any subject of this realm may sue upon such a condition as Mr. Justice Hull was so very indignant at in that particular case. That shows, therefore, that the rule which the learned judge, whose opinion is now before the House, thought depended upon some rule of common law, regardless of policy, was founded upon public policy, and has been restrained and limited and qualified up to this very hour, and beneficially so, by that very policy which it is supposed had no bearing at all upon the foundation of the rule. (*Egerton v. Earl Brownlow*, 4 H. L. Cas., 1, 237, 238.)

It is now about 20 years ago that the notable consolidation of the London, Chatham and Dover and the London and South-Eastern lines was effected, which operated to merge two theretofore independent parallel and competing lines and to allot the whole southeastern section of England to the amalgamated company. This, as is usual in that country, was accomplished through special Parliamentary powers, which in this case were sought and obtained without arousing any great opposition, engendering any considerable heat, or provoking any declamation about a sacrifice of the rights of the public. In point of fact, nothing but good seems to have flowed from it.

Previous to 1899 both these railways had

achieved an unenviable notoriety for the inadequacy, slowness and unpunctuality of their services, for the dilapidated condition of their stations and rolling stock, and generally for the backward state of their accommodation. In the case of the Chatham Company the financial position was also precarious, and though the South-Eastern at one time was nominally much stronger in this respect, it too had lost much ground in the preceding five years, and for 1901 its ordinary dividend at the rate of only 2 per cent was the worst in its history. Competition of the worst kind between the South-Eastern and Chatham companies was a normal state of affairs, and as the result both railways spent vast sums of capital and revenue for which there is at the present time little to show except duplicate lines and stations, and inadequate provision for traffic where extended accommodation was most required. Many times a fusion of interests had been urged upon the two companies, but without result. Negotiations for amalgamation were entered upon several times, but they always broke down at the crucial moment.

At last, in 1898, an agreement between the two companies was reached, not for a complete amalgamation, but for the pooling of gross revenue and working expenses and the division of net profits on a fixed percentage basis, with additional arrangements for the joint contribution of capital required. It was not the intention of the two companies to seek Parliamentary authority for this arrangement, as they were not bound to secure the sanction of any other body than their shareholders. But the government virtually intimated that the new arrangement was so important and far-reaching in its bearing on the interests of the public, that the terms of agreement ought to be embodied in a bill. This bill received the royal assent on 1 Aug. 1899, and seven months thereafter the new arrangement came into operation.

The preamble of the bill recites that

With a view to avoiding undue competition and unnecessary expense and delays and other inconveniences arising from diversity of interests and to turning to the best account the respective powers and resources of the two companies . . . it is expedient and will be for the public advantage that, subject to the provisions and enactments in this Act contained, the undertakings of the two companies should be used, worked, managed, maintained, and improved from and after the passing of this Act, as one undertaking. . . .

The Act constituted a Managing Committee to administer the two railways as one company, that new body being made up of the directors of the two companies.

The committee of 1872 sum up their view upon the effect of hostile or prohibitory legislation on this subject as follows: "A long and varied experience has fully demonstrated the fact that, while Parliament may hinder and thwart it, it cannot prevent it." The theory of the British Constitution is that Parliament is omnipotent, and here there is formal admission that there are things that omnipotence cannot do.

France.—The French railway system was developed a little later than the English, but we must look as far back as the reign of Louis XI, in the latter part of the 15th century, if we are fully to understand and appreciate that development. That sagacious and masterful prince, who reigned from 1461 to 1483, broke effectually the power of the great feudatories, and by a

consolidation of authority in the Crown laid the foundation of the absolute monarchy. His taking the postal service out of the hands of the feudal authorities and away from the cities and making it a matter of national administration, these 400 years ago and more, was one of the most notable acts of his reign, and was in a way the first step toward the modern railway system of France. "Modern history," says President Hadley, in speaking of the nationalization of the French post office, "—the history of nations as such—may almost be said to have begun at this point." What Louis XI did for the power of the Crown and for the postal service of the country, Louis XIV and Colbert did in laying the foundation of the national system of highroads and canals. The *Ecole des Ponts et Chaussées* was founded, and trained engineers graduated therefrom laid out, constructed and perfected that splendid system of canals and highways, radiating from Paris and reaching every corner of the kingdom, which long ago made France the first country in the world in its roads and waterways. There was from the beginning complete organization, intelligent survey and construction and strict supervision; so that an almost perfect system of lines of communication existed in France before railways were known. In no other country had such results been accomplished in road-making, and nowhere else was such completeness of organization and development possible. The genius of highways had in some sort come down to France as an inheritance from Rome, whose military roads were one of her most characteristic monuments. In this state of case, with a perfect system of roads and canals already built and in operation—which made railways seem less necessary in France than in other countries—it is not strange that the French built railways slowly and cautiously. So it was not merely accidental that France moved tardily in this matter. It is not in the French character to make radical changes, or to do things piecemeal; and it was easy for her highway engineers to see that other nations were blundering in their first railway construction. The racial qualities that distinguished the French, their spirit of order and economy, their notion of proportion and their conservative good sense in business, all had something to do with their making haste slowly in railway building. It is very much the French way to let other people make the initial experiments in new things, and only to take a thing up when it is demonstrably sound and feasible. It is almost a racial instinct, and this is what happened in the development of French railways. The result is that they now possess the only railway system in the world which was intelligently conceived from the outset as a unit, which was scientifically planned and laid down by competent engineers working together to a common end, and which was built as a whole. The conditions in France that made this possible had their genesis in the dominating sagacity and spirit of order of Louis XI. The highways and canals led up to the railway lines, and the governmental regulation and control of the old land waterways grew naturally into the present system of railway supervision. The system of roads and waterways existing in 1830 suited the French nation exactly. They were so arranged and classified that each bore its exact proportion of importance, whether national, depart-

mental or local. They were regulated from Paris with ease and with military precision. Never was there so efficient a corps of engineers for carrying out such a scheme as that which is trained at the *École des Ponts et Chaussées*. The first step taken by the government looking to a general railway system was the appropriation of a sum of money to pay the government engineers for laying out a general system of railway lines covering the whole of France. When this survey was completed, and while the lines existed only on the maps and blue-prints of the engineers, the government next took up the question of ownership and management. While other countries had been acting and experimenting and making costly mistakes, France had been reasoning and thinking the matter out. There was a long series of debates in Parliament between 1837 and 1840. The plan finally adopted was the conception of Thiers, and was settled upon in 1842. The plans then and thus deliberately conceived and matured — both of engineering and of legislation — have since been carried out consistently. They were sufficiently elastic to be practicable. It was at the outset a policy of support and control without actual ownership, or, in other words, a policy of subsidies to encourage private companies, and in return for these subsidies a reservation of more or less important rights of state control. As the work proceeded and as new conditions arose, amendments and modifications were incorporated into the plan as originally conceived. In 1842 it was strictly a plan for subsidies; in 1852, extensions of chartered privileges were granted to the companies; in 1859, a scheme for the guarantee of interest on the bonds was inaugurated, and, in 1883, the government guarantee was extended to dividends.

Under the plan adopted 33 different companies were chartered, contemplating about 2,500 miles of line. Building went on rapidly until the Revolution of 1848, and then again after the accession of Napoleon III in 1851. The lines have from the beginning been laid down with the idea of avoiding all duplication and all waste of capital; they were surveyed and traced by government engineers, and each part stood in its proper and intelligent relation to the whole. Parallel lines were forbidden as a matter of course, and competition was not conceived of as among the possibilities of the situation. By 1852 the number of independent systems had been reduced from 33 to 11, and in 1859 the 11 were reduced to six, of which five radiated from Paris. Each had a monopoly in its own territory. Competition running riot, the construction of needless lines as a mere speculation in the securities, rate wars, with their attendant iniquities, and the consequent wanton waste of money and effort in construction and operation are essentially unthinkable to a French railway engineer or official. New construction is undertaken only as required, and to meet the necessities for more lines growing out of the development of any particular territory. About 1859 it became obvious that a considerable amount of new construction was necessary in order to bring the railway system up to a proper standard of utility and efficiency, and in order to secure this construction, each of the six companies, and each in its own district, undertook to construct a large number of branch lines.

The government took the initiative, and in order to facilitate this new work and to secure it promptly recourse was had to a system of state guarantees of interest on the bonds upon which the money for the new construction was to be raised. This was the plan devised by De Franqueville. Money was, of course, easily raised by issues of bonds upon which the government guaranteed 4 per cent, this guarantee making the securities instantly marketable and extremely valuable. There was, accordingly, no wasteful financiering, no iniquitous jobs, no lack of funds, no foreclosures, no reorganizations, receiverships or squeezing of investors. In 1865 a further plan was proposed in the Chamber for the construction of a network of local roads not to belong to the six companies, and the municipal authorities were given the right to subsidize such lines. Pursuant to this plan, several thousand miles of these local lines were built throughout the country within the next five years. It was not, however, contemplated that they should be combined into systems which might interfere in any way with the monopoly of the six companies. They were designed to be feeders. However, after the war of 1871, the prohibition to combine was successfully evaded, and these local lines by a series of combinations began to be serious competitors in many places to the main systems. This made it necessary for the government to take the matter again in hand, and the problem was ultimately solved by having the great companies take over the local lines within their territories severally, upon terms. In 1879, by a decree of July of that year in the Chamber of Deputies, De Freycinet undertook to raise a loan of 3,000,000,000 francs for the construction of about 10,000 miles of additional line. This plan has been slowly carried out since that time. There was at first some delay, but by the beginning of 1884 this last comprehensive scheme of railway development was settled upon, the leading points of which were these: first, that the state hereafter should confine its own railway operations to the small district in the southwest occupied by what is known as the state line; that isolated lines which the state owned in various parts of the country should be taken over by the one of the six great companies in whose territory it lay; second, that additional lines as needed should in future be constructed only by the companies in whose district they belong; third, that the state should guarantee each company a minimum dividend, and that when the amount available for dividends exceeded a certain percentage — the rate differing for each line — two-thirds of the excess should go to the state. The limit, however, was placed so high that this provision has been practically inoperative. Thus, for example, on the Northern line, the guarantee minimum dividend is 13.5 per cent, while the point beyond which the state shares the excess is 22.1 per cent. In the case of the Paris, Lyons and Mediterranean, the guarantee minimum is 11 per cent, the state sharing in anything beyond 15 per cent, and so on, with slightly lower percentages for the other companies.

All of the lines in France except the old state line in the southwest and the western line taken over by the state a few years ago to placate the Socialists, are owned and operated by private companies. They are

concedés and become state property upon the expiration of the concessions. Meantime they are subject to a strict governmental supervision and control. The length open for traffic by the latest figures obtainable (1911) was 25,194 miles, which fully meets all the requirements of the country. Of this total mileage 5,559 miles are state railways. The original scheme was for the government to contribute about 250,000 francs per mile; and private enterprise to find about 200,000 francs per mile, thus dividing the expense and the ownership. The concessions generally were to fall in, first in about 40 and later on in 99 years. When this occurs—about the middle of the present century—the government will, it is claimed, become possessed of an asset in the shape of railway property sufficient in realizable value to pay off in full the national debt. In 1892 the French railways were conservatively valued at 16,000,000,000 francs. The original plans of construction and joint ownership were somewhat modified as time ran on. In the construction of the French lines there has been less waste of capital and better results for capital than elsewhere in the world. French railways have cost less and come to more than any others on earth. It need not be argued that the French scheme put in practice would inevitably reduce the cost of construction to a minimum and would secure the best results for the least money. Passing by the matter of the state guarantee of interest and dividends, it may be said that the net earnings of the five private companies have been upon an average far beyond anything accomplished elsewhere in the world in that respect from railway operation. Furthermore, in face of the strong position of the French railways as monopolies, the government notwithstanding exercises a sufficient control—one which is in many respects admirable and reasonable. The French plan, as is seen, forces the numerous independent companies to work in harmony with one another, while giving each of them an absolute monopoly in their own territory. It renders, therefore, the process of consolidation within that territory easy and inevitable. Whatever slight attempts have been made in the Chamber to check or prevent combination or monopoly have been promptly overruled as contrary to the general scheme. This was particularly the case in 1875, when Phillippart, a Belgium capitalist, undertook to consolidate the local lines as against the six companies; and even the state itself in the operation of its own lines in the southwest has never succeeded in breaking into the monopoly of the Orleans Company in that territory. While France prohibits effectively competition between her railway lines, she is constantly spending large sums in improving internal water communication; and private carriers using these waterways without paying any toll carry off more or less traffic from the railways, and are allowed to do so. To make a summary statement, we find the facts to be that in France the railway system was intelligently planned as a unit from the outset; that the lines were laid down by competent government engineers and constructed without paralleling; that in consequence very little money was wasted in construction; that competition did not enter into the scheme as originally devised, and that when it arose—notably through the consolidations of

the network of local lines built between 1865 and 1870—it was suppressed by the government; that railway investments have been almost uniformly profitable, and upon the whole much more profitable than in other countries; that freight rates are not excessive and that passenger rates are very low; that the public is well served, the passenger service especially being of the very best; that governmental regulation is not hampered or thwarted by the strength of the railways as monopolies; that no mischief and much good seems to have come from the elimination of competition between lines, and that upon the whole the French scheme secures a maximum of adequate, efficient and satisfactory service at a minimum of cost and friction.

Belgium.—The policy of government ownership is perhaps best typified by the Belgian system. Of all countries in the world Belgium probably offered the best field for a state railroad. The country is small, compact and rich, the population crowded, active and intelligent, and the industries varied, all which insured a large volume of local traffic. Moreover, Belgium is on the highway between England and Germany, so that, in addition to a dense local traffic, the Belgian lines were certain to secure considerable through traffic on commodities moving between England and Germany. There was in consequence of all this little room for mistake in locating the main lines, and they were, as in France, for the most part laid down intelligently and built economically. Railway construction began as early as 1833. Private companies were allowed to build lines wherever the state did not choose to build, but competition between the lines owned by private companies and the state lines was not at any time part of the original scheme. Like the French, the Belgians saw from the start that competition would be uneconomic and wasteful. The private railways increased rapidly from 200 miles in 1850 to 700 miles in 1860, and 1,400 miles in 1870. This rapid growth of the private lines was accompanied by their inevitable consolidation into systems, and in spite of the fact that competition had not been contemplated, there began in Belgium about 1856 a period of railway war between the state and the private lines and among the private lines themselves. Theoretically, the state had and exercised the power to forbid the private companies from entering into any competition with the state lines, but, in spite of that, competition in Belgium after about 1856-57 was keen. The state had the better routes and in some sort the inside track, but some other advantages possessed by the private companies practically offset this advantage. This competition working the usual mischief finally drove the government to the expedient of buying out the private companies. This began about 1870. By 1874, the government owned more than half the mileage of the country. By 1880, it owned two-thirds, and in 1902, there were 2,516 miles of railway in the country, all or practically all of which is controlled by the state, either through ownership or lease, and competition is in consequence wholly eliminated. The total mileage in 1912 was 2,913, of which but 217 miles were private lines. The state now owns more than 90 per cent of the total mileage and operates almost all of the remaining by lease. This is in brief the history of

the development of railways in Belgium. It appears that competition was not part of the original scheme; that it nevertheless arose and ran its course; that when the state realized the disadvantage of it, steps were taken to eliminate it entirely, and that this was done by the purchase of the competitive lines. There was at first the inevitable consolidation of the private lines, eliminating competition between those lines themselves, but intensifying it as between them and the government lines. Then came the consolidation of these lines with the state-owned lines by government purchase, and competition was at an end. It is another case of the universal tendency to combine, and of the powerlessness of government to prevent it.

Italy.—In 1878, a Parliamentary commission in Italy undertook an investigation of the railway situation in that country. Testimony was taken throughout the kingdom and an enormous mass of material collected. In 1881 this commission made its report to the government, which was subsequently published in seven quarto volumes. It was the most thorough railway investigation ever undertaken in the world and the report is probably the most valuable in existence. The material parts of it have been translated into French and are thus available. From the work of this commission it appears that, prior to the wars which resulted in the union of the Italian states in 1870, the principal railway lines of Italy not only were disconnected and independent of each other, but also constituted isolated or strictly local systems for each of the chief independent states. Thus the lines in Tuscany, in Lombardy and in Piedmont were wholly distinct both from one another and also from those centring in Venice, Rome and Naples. Some of the early charters had come from the emperor of Austria and one from the Pope; the lines were inadequate to the demands of the business of the country, the service was very poor and the companies substantially bankrupt and irresponsible, but there was plenty of competition. The problem after 1870 was to unite and consolidate these scattered and local lines into systems fit for united Italy, to construct new lines, to reconstruct old ones, to re-equip and to reconstitute; and then to operate the reconstructed lines as a whole. The range of mountains from north to south which constitutes the back-bone of the Italian Peninsula dictated a natural division of territory for the amalgamated lines. There was as of course much local jealousy to overcome. Although Italy was too poor to spend much money in experiments, there was thought to be danger to the autonomy of the new state in permitting foreign capital to come into the railways, and it was prevented by the government, so that, in consequence of all these matters and hindrances, things at first moved slowly. Connecting links were first built, which served to unite the isolated local systems, the plan being to consolidate the local parallel and competing lines rather than the connecting lines. Finally the roads fell into four systems—that of Upper Italy, that of Rome, that of the east coast and that of Sicily and the south. Here, as elsewhere in Europe, competition between parallel lines did not enter into the scheme of construction and reconstruction, and consequently consolidation was not only inevitable,

but easy, and it was facilitated wherever there was duplication. Upon the division of territory between the four systems and with the consolidation of lines within those four territories respectively and the building of the connecting links, the problem of construction was in a way to be solved; or, in other words, the lines were laid down and ready for operation. Next came the problem of ultimate ownership and present maintenance and operation. Soon after 1870 the state had begun to buy up the lines, especially in the north, where there was danger from Austrian influence, and by about 1875 a considerable part of the mileage of the kingdom was owned and operated by the state. So that by that time Italy seemed committed to what may be called the Belgian system of state ownership and operation. But Belgium was rich and Italy was poor, and it was soon found that the state was neither managing the lines well nor making any money out of it; there was, therefore, general dissatisfaction throughout the country with the railway system; neither the poorly served public nor the depleted treasury of King Victor Emmanuel was satisfied. It was in that state of affairs that the investigation of 1878 was undertaken, the result of which was that the Italian statesmen who had the matter in hand came to the conclusion that it was not the proper function of the Italian state to run its railways: that state management in Italy had proved more costly and less satisfactory than private management, and that the carrying on of so vast an undertaking by the new state involved political risks and dangers of a serious nature. The outcome was the chartering in 1885 of three private companies, one, the Adriatic, for the territory on the east of the Apennines, a second, the Mediterranean, for the territory on the west, and a third, the Sicilian, for Sicily, the two systems in the peninsula being about equal consequence, while the one in Sicily was, of course, smaller. A fourth company has since been chartered to operate the lines in Sardinia. These companies were to take over the rolling stock of the lines within their respective territories at a valuation, and thus become the owners of it, and to maintain and operate the lines, dividing the gross receipts with the state on an agreed basis. So that the ultimate solution was that the state was to own the lines, where private companies were to operate them. Practically the railway business of Italy proper is in the hands of two companies, one on either side of the Apennines, the lines meeting at Naples, Rome, Florence, Milan and elsewhere. Between 1881 and 1897 the length of the Italian railway system almost doubled itself, and in 1898 there were 9,813 miles of line open for traffic. Since which time there has been practically no increase in the mileage. In 1912 there were reported 8,387 miles of state railways. The service is satisfactory and the railway system is making rapid progress throughout the kingdom. Thus we see that in Italy competition preceded combination; that it was found to work mischief and that attempts at combination were the inevitable result; that when the matter was taken seriously and intelligently in hand by the state competition was eliminated by law and the territory divided; and that then, and then only, were satisfactory results secured in railway

operation. It appears, therefore, that whether we choose state operation as in Belgium or reject it as in Italy, it is the same as far as competition and combination are concerned; that the same economic laws govern in each case, and that in the long run competition is eliminated.

Germany.—Railways in Germany grew up very much as they did in England, at first without any general plan and without any real comprehension or appreciation of the problems involved. The Germans, however, like the English, seem to have started right on the question of competition. Their earliest statutes explicitly recognized the right to a monopoly in their first lines. The country then consisted, aside from the central kingdom of Prussia, in large part of a number of semi-feudal principalities, and local railway system sprang up in each of the states, which in 1914 constituted the German Empire, so-called. Prussia followed Belgium in a general way in her early legislation and initial construction. The first state railway in Germany was built in Prussia about 1848-50, from Berlin toward the Russian frontier. Other state lines followed, but *pari passu*, many private lines were laid down, some of them securing some state aid, by way of guarantees or subsidies or stock subscriptions from the principal states. Some, however, even of the smallest principalities, at first owned their lines outright and operated them too. So there was at the start every sort of a railway in Germany. This haphazard and piecemeal work begot the inevitable result—fierce competition everywhere among the private companies and between them and the state roads. The results were extremely dissatisfactory; the service was poor and the rates high. About 1861 Bismarck came into power, and from that time dates the influence of militarism upon the railway system of Germany. It has since shaped and colored the whole development and operation of the German lines. He saw clearly enough that the mixed and competitive system was a bad one, not only from a military point of view, but also from the point of view of the country at large. Steps were, therefore, gradually taken, in Prussia especially, to acquire the private lines and to consolidate competing and conflicting interests. The matter moved slowly because the country was poor, but the mileage nearly doubled between 1865 and 1875. After the war with France in 1871, more rapid progress was made in unifying the railway system of the country. By 1878, there were about 3,000 miles of state-owned and operated lines, 2,000 miles of privately-owned and state-operated lines, and about 6,000 miles of privately-owned and privately-operated lines. In 1881, the government owned more than 7,000 miles of line, only about 3,000 miles remaining in the hands of private companies. In 1885, the government owned 13,000 miles of line in Prussia alone while only 1,000 miles remained in private hands. In 1900, there were 30,597 miles of railway in the German Empire, more than 93 per cent of which were owned and operated by the state. In 1913 the total mileage was 37,894, of which 2,205 miles were private lines. The increase since 1900 consists almost exclusively of lines constructed for military reasons mostly on the western fron-

tier facing France. Under the law the government was required to manage the railways "in the interest of general traffic as a single system," and in 1886 the government issued a Code of Railway Regulation, applicable to the whole railway system of the country. Competition practically ceased in Germany by about 1875, and for the past quarter of a century the railways of the country have been operated on non-competitive lines. Pooling arrangements with the canals and other competing waterways are sanctioned, in order fully to eliminate wasteful competition and unjust discrimination.

Austria.—In 1912 Austria had 14,185 miles of railways, of which 863 miles were narrow gauge and 2,501 were private lines; Hungary has at the same time 13,303 miles of lines, of which 2,098 were private lines. In 1901, Austria-Hungary had only 39,014 kilometers of line open for traffic. The first Austrian charter was granted in 1836, and construction went on actively thereafter until the revolution of 1848. The original idea was to follow the French system, and have the lines built and operated by private companies. Their statute of 1838, it may be noted, was the first general railway law enacted in any country in the world. It provided for undertakings by private companies, and for guarantees by the state of interest upon the cost of construction; it limited dividends on shares to 15 per cent, and absolutely prohibited the construction of paralled lines. It was discovered, however, as time ran on, that the French system was not well suited to the condition of things in Austria; and in spite of statutory prohibition, as the lines were constructed and put into operation, competition ran riot. There was also the usual iniquity growing out of constructing lines for a chance to speculate in the securities; and the competition of the waterways—of the Danube and the canals—although pooling between them and the railways was allowed and encouraged, added to the confusion and disorder of private management. So in 1873, Austria fell into line with the other countries of Europe, and started off in the direction of state ownership and control. In 1885, about three-quarters of the mileage in Austria was, however, still in the hands of private companies, but all the lines in Hungary were at that time owned and operated by the state. By 1898, more than half of the Austrian lines were under state management, and the tendency sets more and more in that direction.

Russia.—In 1910 Russia (including Russia-in-Asia) had 41,622 miles of completed railway, not including Finland with 2,039 miles of line, and 8,000 miles under construction, including the great Trans-Siberian line, which is the greatest railway enterprise yet undertaken anywhere. Work began on this line in March 1891, and it is now open for traffic. The estimated cost is about \$500,000,000. The distance all rail from Paris to Port Arthur or Vladivostok is about 7,000 miles, with a through-car service from *la Gare du Nord* to Port Arthur and Peking. The government furnished a large part of the capital required for construction, and owns and operates about two-thirds of the total mileage in European Russia; it has in addition subsidized and thus controls and dominates the policy of the lines owned and operated by private companies.

The Minor Countries of Europe.—Elsewhere in Europe we find the same variety in railway operation and control as in other things; but the tendency everywhere is to government ownership or to such a strict government regulation as effectually eliminates anything like competition between the lines. Thus in Norway, in 1915, there were reported 1,948 miles of line, all now owned and operated by the government; whereas in Sweden, at the same time, there were 8,984 miles of line in operation, of which only 2,392 were government lines. But although in 1893 there were reported to be not less than 108 different owners of private lines in Sweden the law strictly and successfully prohibits competition between them, or between them and the state lines. The last available figures for the Spanish lines show 9,517 miles open for traffic in that country, all, as in Portugal, owned by private companies, but supported and controlled by the state. In Switzerland, where in 1915 there were 3,148 miles of line in working order, the governmental supervision has until recently been much the same as in Spain. In 1898, by popular vote, it was determined (in view of the evils of over-construction and some hurtful competition in spite of legislative prohibition) to purchase for the government the five chief lines, thus putting Switzerland in the Belgium class of countries owning and operating their railway lines. This scheme was gradually financed and carried out by the Swiss government. The railway history of these relatively unimportant European countries is of much less interest and value to us than that of the greater states. The Italian system has been followed substantially in Holland, and in Denmark, and by some of the other minor Scandinavian countries.

India.—The construction of railways in India, which commenced in 1853, has been conducted on three different systems: first, the employment of companies under a system of guarantee; secondly, by the state through its own officials; and thirdly, by assisted companies either with or without guarantee or subsidy from the state, and working with capital wholly raised by themselves or partly with capital provided by the state. Out of eight lines constructed on the first system, five have been purchased by the state. Two of these are worked by companies. The more important, the East Indian line, is carried on by the same company that constructed it in the first instance, on special terms as to the sharing of profits. The second, the South India line, is in the hands of a new company, whose capital was subscribed by the shareholders of the old one. The three remaining lines are worked by the state, and all five come into the category of state lines in the accounts of the government of India. The total number of miles of Indian railway open for traffic in 1915 was 34,572. Although construction began about the middle of the last century, the system has been developed almost entirely since what English writers on railway problems speak of as "the rise and fall in England of the great fever known as the railway mania," to which detailed reference has hereinbefore been made. The Indian railways were, therefore, planned and constructed in the light of the experience afforded by the home

construction and development, and many of the cruder home blunders were thus avoided. They now fall into one or other of four classes: (a) State-owned lines, worked by companies; (b) state-owned and state-operated lines; (c) lines constructed by guaranteed companies and (d) lines constructed by assisted companies. The English government, following the French lead in that respect, provided for a system of guarantees, by which the necessary funds were cheaply found; in laying down the lines paralleling was avoided, and competition effectively prevented. Where there is no competition there is the less incentive for combination, and there seems, therefore, not to have been any great tendency in the Indian lines to combine. These Indian railways seem to be rather poor affairs; there is much complaint of indifferent service and high rates. How far these things may be chargeable to the inefficiency of the government or may be due to the system itself does not appear. They have up to the end of 1899 involved a yearly loss to the Indian revenues, but the working of the year 1900 resulted for the first time in history of the Indian railway system in a net gain to the state of Rs. 87,239, and in 1901 Rs. 1,154,119. From the commencement of railways in India, about half a century ago, to the end of the year 1899, the loss to the Indian revenues amounted to Rs. 57,811,487. Whatever else may be true of the Indian lines, they have been constructed and are operated entirely on the principle of non-competition and division of territory, and there being no competition there has been little tendency to combine; in other words, the evil of competition not existing or not being allowed to exist, there is no call for combination. This is, as has been said, negative evidence in support of the contention that wherever competition is possible combination is inevitable.

Mexico.—The railway situation in Mexico is fully disclosed in an exceedingly valuable report made some years ago to the government by Senor Limantour, Secretary of Finance. It purports to have been based upon a careful investigation of the facts, and is on the face of it as intelligent and comprehensive a state paper as any that has emanated in recent years from any government office anywhere in the world upon the subject. The fact that Senor Limantour, who was then virtually prime minister of Mexico, and had been nominated by President Diaz as his successor in the presidential office suggests his high standing at home and gives weight abroad to his views on these questions. This report, which seems largely to speak the voice of the secretary himself, deals at length with the problems of competition and combination, and discloses the fact that the policy of the Diaz administration, as now settled and determined, is to meet and solve these problems by absolute government ownership, rather than by any further futile attempts at legislative control. The government, finding that the general railway law of 1898 (from which, when it was passed—as in the case of our original Interstate Commerce Law—great things seem to have been expected) was proving inadequate to the due regulation and administration of the lines, and realizing the necessity of stronger and surer governmental control, has lately come to the policy of going into the open market and of

adopting the same tactics as private individuals or companies in purchasing the shares of such lines as it desires to control. Mexico is, therefore, now fully committed to the theory of governmental ownership, if not to that of governmental operation. Those portions of Señor Limantour's report which disclose the processes by which the government has acquired and is acquiring such a proportion of the shares of the leading lines as will give it due preponderance in their control are very interesting. The explanations of the causes which have moved the government to this step, as contained in the report, are of an even wider interest and significance to students of the railway problem. In brief, Señor Limantour's explanation is this: The government has until recently been in the usual elementary attitude of encouraging by concessions, subsidies and otherwise all the railways which either citizens or foreigners would undertake to build and operate as private enterprises, in the supposed interest of the most rapid possible development of the country. It was only in 1898 that a general railway law was passed, which, however, soon proved entirely inadequate. It was, therefore, in addition found necessary to prescribe new rules relative to granting concessions for competing lines between points already connected, and to establish a tariff commission—something like our Interstate Commerce Commission—which was an attempt, through the agency of a governmental bureau, to prevent combinations in freight rates, and to regulate them in the public interest. In the light of the experience of other countries—and, as it appears, especially in the light of the experience in the United States—competition between the lines is by this report pronounced harmful, "except where traffic is large enough to support it"—whatever that means. Government ownership and regulation is declared to be the only real preventive or remedy against such disastrous competition—with its inevitable result of the consolidation of competing interests. It is further suggested that the fact that groups of foreign capitalists had undertaken to consolidate several of the principal lines, obliged the government to take a definite attitude lest their great railway properties should thus be taken over and controlled by alien capital. It was clearly seen that these contests for territory between the hitherto conflicting interests would eventually and inevitably result in either the forced or the voluntary consolidation of the competing systems. The law as it stood was inadequate to prevent the acquisition in the open market by any private interest of a control of the shares of any company sought to be acquired, and there was no way to prevent the consolidation of interests through voting trusts or otherwise. Specifically, the situation in the early part of 1902, which seemed to drive the government strongly in the direction of state ownership and control, was this: The railways of the country were found already to be in the hands of no more than four groups of capitalists, namely, the Central, the National (having lately absorbed the International), the Interoceanic and the Mexican—all but the last showing great expansive activity. The Central especially, by the recent purchase of exclusive port concessions and the building of new lines in and out of the City of Mexico, was threatening to cripple the National line. Plainly, therefore, consolidation

between it and the Central would inevitably follow in the ordinary course. Meanwhile, through Messrs. Speyer and Company, the National was trying to acquire the control of the Interoceanic route, but this was frustrated by the government. Various circumstances favored the government as against the foreign bankers in its secret move to secure control of the Interoceanic's debentures. "The ability and high financial standing," says the report, "of the firm representing the interests of the Mexican National constituted a serious obstacle to the attainment of our aims, and it was necessary to act as we did with decision, rapidity and absolute secrecy." A proposition for a common exploitation by the government in association with the National, the International and the Interoceanic companies followed: "but it was soon recognized that such an arrangement could not have the necessary durability nor afford the indispensable conditions whereby the companies might secure themselves definitely against the hostility of other corporations to which they might be exposed in time." The government thereupon, wisely declining to be drawn into any partnership arrangement with the companies, reverted to its original plan, namely, an arrangement such as would give the state primary and absolute control of the three systems, and in such a way as to protect each of them against such future competition as would be sure to arise under the existing state of things. The report declares that the government has now determined to grant no concessions hereafter for competing parallel lines, except in territories where dividends can be earned by each such line. Several voting trusts, in some of which the government has had an interest, have existed in Mexico, but some of these have lately been dissolved upon the advice of American counsel.

It was at first proposed that the government should exercise control of the new consolidated system through the voting trust of the National, already in existence. But, "according to the valued opinion of American attorneys, who are specialists in affairs of this nature, it would have been attended with many objections of a legal character, and have proved a fruitful source of litigation." Accordingly, the consent of its three members was obtained, and the voting trust dissolved, an agreement being entered into with Messrs. Speyer and Company whereby they were to secure for the government 40 per cent or more of the voting shares. The report then enters into a detailed account of the steps by which this was successfully accomplished, 47¼ per cent of the shares being thus secured. It also goes fully into the question of the probable earnings of the consolidated railways and of the issuance of treasury notes for \$12,500,000, American gold, to pay for them. The advantages to the government, growing out of the control of the new consolidated system, is summarized in the report as follows:

1. The having obtained by one stroke the control of the lines belonging to the National and International without losing control of the Interoceanic.
2. Having secured a considerable reduction in the total cost of the operation; and
3. The ability to effect payments in such manner as in no wise to disturb the equilibrium of the budget, and out of funds which in the long run will be recovered by the state.

Repeated reference is made throughout the report to the railway situation in the United

States, and it is obvious that American experience has influenced the Mexican government in its new departure in the direction of state ownership. From a return prepared by the French Ministry of Public Works, it appears that there were in Mexico in 1870 no more than 349 kilometers of line; that in 1880 there were only 1,120 kilometers, while in 1890 there were 9,713 kilometers, in 1900 a total of 15,454 kilometers and in 1917 15,805 miles of railway in operation—now, as we have seen, all substantially under government control or presently to pass thereunder, as the result of the investigation and comparison of the advantages of private versus government ownership and operation set forth in Señor Limantour's report.

Australia, etc.—In Australia, state ownership and control has since about 1860 been absolute and universal. The latest available statistics show 21,959 miles of line open. This includes about 2,500 miles of line in New Zealand. While there was at first some construction by private companies, every mile is now state railway. The figures intimate that there is no serious competition there.

South America and Africa.—In South America the governments generally own the lines. In Brazil, in 1915, there were 15,491 miles of line open. Of this mileage the state actually owns but a small part, but it subsidizes the rest and thus exercises an efficient control over all, which effectually prevents duplication and competition. In the Argentine there were reported in 1915 20,593 miles of road, mostly government lines. Chile in 1915 reported 3,949 miles open, of which 1,458 belong to the state. The French possessions and dependencies in North Africa reported, in 1900, a railway system amounting to 4,628 kilometers in length, as against 3,595 in 1890 and 517 in 1870; British South Africa seems to have had, in 1900, nearly 6,000 kilometers of lines in operation. There were about 2,000 kilometers of line open in the Transvaal at the commencement of the Boer war and about 400 kilometers in the Kongo in 1900. The total length of all operated lines in Africa, including the foregoing, the Egyptian lines (2,063 miles), and some little development in Portuguese East Africa, amounted in 1915 to about 23,472 miles, substantially all of which is government line. Competition and combination are, therefore, not open questions in Africa. The several European countries that have built the lines there either operate them directly or see to their operation on a strictly non-competitive basis.

Conclusion.—From the foregoing general view of railway history and development throughout the world, it appears that there is a universal and irresistible tendency in competitive railways in the same territory to combine and to divide the territory between them; that attempts by legislation or litigation to prevent it have uniformly failed; that states which at first recognized and sought to enforce the principle of competition between railways have one after another ultimately abandoned the attempt; that nowhere, except in the United States, is the principle of competition now recognized or still sought to be enforced; that railways in new countries or colonies of old countries, constructed during the last quarter of a century in

the light of the experience of the older countries as to competition, have been constructed and operated from the start on non-competitive lines; that the amalgamation of parallel and competing lines is entirely consistent with good service, reasonable rates and adequate governmental supervision and control; that where railways compete there is always an enormous waste of capital and effort and frequently poor service and high rates; that the tendency everywhere is to eliminate competition where any measure of it still exists; that government ownership is good or bad according to the point of view; that there is a strong tendency in Europe and elsewhere except in the United States and in England, toward government ownership and operation; that the governments of Europe, with 10 times the police power of our own, have long since abandoned all attempts to hinder and thwart the laws of trade and commerce by restrictive legislation, or to prevent the inevitable in railway development; that, instead of opposing this economic evolution, the most enlightened European governments have on the contrary legalized it and seek to enforce and regulate it in the public interest; that the best and cheapest service is secured where competition is impossible and where the state puts the emphasis of its effort, not on interference with railway finance, but on securing good service at fair rates.

RAILWAY CONSTRUCTION. See RAILWAY ENGINEERING AND CONSTRUCTION.

RAILWAY CONSTRUCTION, Street. See STREET RAILWAY CONSTRUCTION.

RAILWAY ENGINEERING AND CONSTRUCTION. In railway engineering the railway track more than any other part of the railway machine had a crude beginning and has reached its present condition of excellence by a continuous series of improvements. In the first stages of construction, tracks of numerous designs were built, the chief thought of the builders being to secure a solid structure that would not allow the rails to spread. The track was of necessity relatively heavy and expensive in relation to the weight of the rolling stock and volume of traffic. Three kinds of rails were used, the one most generally employed consisting of strong wooden beams, surfaced with strap iron. The iron rails first used were cast and their length did not exceed three and one-half feet. Rolled rails were soon substituted for those of cast-iron and the length was increased to 15 feet, with a weight of about 40 pounds to the yard. Up to 1844 all rolled iron rails used in the United States were 15 feet in length. The T-rail now universally employed was not much used during the first 20 years of railroad construction. Since 1870 rolled steel has been used instead of iron and the weight of the rail has been steadily increased to 110 pounds to the yard. One hundred pounds to the yard has become the standard upon tracks where traffic is heaviest. The standard length of rail has been maintained at 30 feet, but at the present time some track is being laid with rails 60 feet in length. Along with the improvements in the track, bridges and other structures have been strengthened to meet the necessities of the modern transportation methods.

The whole trend of modern engineering is toward constant increase in the search after and adoption of labor-saving appliances, on the one hand, and constant increase in the development and elaboration of systems on the other. This is especially true in railway engineering, and an examination of recent subway, tunnel and bridge constructions and other engineering operations serve to point out the wonderful progress in engineering methods and the present

easy accomplishment of former undertakings either abandoned or considered impossible.

Construction.—A perfect and safe track is complete in all respects when full bolted, full spiked, well ballasted, surfaced, lined and gauged. The best dirt ballasted track is made when laying it, by bedding the ties to a level surface on top before putting on the rails. If it is intended to ballast track with cinders, gravel or stone, as fast as it is laid, the tie bedding is omitted in order to have the full width of the grade upon which to deposit the ballast, but at the same time the ballasting should be kept well finished up to obviate the danger of spoiling the rails. When laying the rails care is taken to give the proper space at the joints for expansion. Too much space at the joints must be avoided in order to prevent the car wheels from battering the ends of the

The Standard Terms and Points for Gage of Wheels and Track.

rails. The coefficient of expansion for steel is .0000065 of its length for each degree. For a rail 30 feet long and a difference of 100 degrees, or from 10° below zero to 90°, the amount to allow would be one-quarter inch. To take up the flow of the rail one-eighth inch must be added, making a total allowance of three-eighths inch. A steel rail expands or contracts 1-100,000 of a length under a load of one ton (2,240 pounds) per square inch. This is also its expansion under a rise of 15° of temperature; consequently, if a 30-foot rail is subjected to a rise or fall of 15°, it exerts a force of one ton per square inch if resisted. Where angle bar splices are used on joints the best method to hold steel and to keep it from creeping down

Quantities of material per mile of single track.

grades or from running ahead enough to throw the track out of line or kink the rails, is to use the slot spikes in the splices. Short rails (less than 10 feet in length) should never be used in making connections except in cases where it is absolutely necessary to use short pieces of rail as at the ends of frogs, in the round house tracks, etc.

Spiking and Gauging.—All track should always be kept full spiked and in perfect gauge. Bad gauging detracts from the appearance of an otherwise good track, makes track easier to knock out of line and down below surface, and is the direct cause of wrecks. The spikes should be driven about two and one-half inches from the edge of a track tie. Both inside spikes should be driven on one edge of a tie and both outside spikes on the other edge in order to prevent the tie slewing and also to assist in holding the rail from creeping. The standard gauge on American railroads is four feet eight and one-half inches; according to conditions, broad gauge is greater and narrow gauge lesser than standard width.

Drainage.—In order to ditch a cut properly it is necessary to take measurements from the rail to the bottom of the face of the cut, at different points along the cut, and ascertain at what average distance from the track the back of the ditch should be located. The width of a cut and the slope of its face on each side of the track will govern, to a certain extent, how far from the track rails to place the back of the ditch. The ditch should be deep enough to thoroughly drain the track and the distance from the rail to the back of it should be in proportion to the depth of the ditch, giving the water an easy fall from the track and free passage through the ditch, avoiding all danger of its washing the shoulder of the grade or undermining the track. As a general rule the bottom of the ditch should be eight to 10 feet from the rails where the grade width will allow it, and about two feet below the bottom of the ties. When the track is ballasted with dirt the slope should commence in the centre of the track two and one-half inches above the ties, falling at the rate of one and one-half inches to the foot. From this point, which is three feet outside the ties, and two inches lower, the incline should be greater, about in the proportion of four inches to the horizontal foot. If the track is ballasted with gravel the slope toward the back of the ditch should commence about two feet outside the track rails, the ballast at this point being level with the base of the rails. To insure a thoroughly good drainage all the water which falls upon the track or adjacent land should be conducted through ditches, culverts, bridges or other channels to the nearest running stream that will take it away beyond all possibility of injuring the track. Where muskrats or minks are plentiful and cause damage to the track by burrowing under it, a heavy coating of cinders and slag along the sides of the embankment is an effectual protection against their depredations. The cinders form an acid in the water and at the same time are too sharp for the animals to burrow through.

Vitrified Pipe Culverts.—The use of vitrified pipe for culverts under railroads has continued in constantly increasing volume since

1878; its advantages are now fully appreciated and experience has pointed out such treatment as will ensure the best results in efficiency and permanency. In northern latitudes especially, where severe cold prevails, the culvert should have a good fall, and be so constructed that no standing water be allowed to remain in the pipes and freeze. When drainage capacity greater than that afforded by one pipe is desired, two or more lines of pipe may be laid side by side. This practice is quite common, and gives an important advantage in that the full capacity of pipes is utilized at a lower depth of water,

Fig. 1. Lines and Surface of an Arch Culvert.

but the separate lines for pipe should be laid far enough apart to secure a solid bed for each one. No arbitrary rules can be made for work of this character. Varying physical conditions must be met and each particular work treated separately on its merits. Under especially favorable conditions of good soil, light embankment and good drainage, there is no doubt that the pipe culvert may be put in without cement and without end abutments, ensuring complete construction at minimum cost; but the durability of vitrified pipe being conceded, the permanency of the work is a prime consideration, and the wisest economy would seem in all cases to suggest the use of concrete as a foundation for the pipe, and that each end of the pipe culvert be protected by parapet walls of substantial stone or brick masonry.

Ballasting.—If stone is difficult to obtain a good track can be made with gravel and stone combined for ballast. The foundation for the track is laid with broken stone and above it placed a quantity of coarse gravel sufficient to bed the ties, surface the track and dress it. Cinders are equally effective as a ballast, except in wet cuts, where stone should be used, and are cheaper than either stone or gravel. Six inches of cinders will absorb about one inch of rainfall, and will thus keep the foundation beneath the ballast dry. They make a superior ballast on clay fills or gumbo bottoms, and are a positive exterminator of weeds. Where the subgrade is well drained and solid, an excellent track can be made by ballasting with two cars of gravel in a place, and to accomplish the work in this way, estimates may be taken at the rate of 325 cars of gravel to the mile of track. The embankment should not be less than 14 feet wide on top before putting on the gravel. Although locomotive cinders, furnace slag, burned clay and gravel make excellent ballasts, within the past few years the best results have been obtained from stone ballast where the stones are sufficiently small to pass through a one and one-half inch ring. The first cost of stone ballast is large; but once in place and thoroughly tamped it is extremely solid, will arrest the

springing action of the track and will ensure a nearly perfect drainage.

Laying Rails.—Owing to the difference in quality and in the amount of traffic over the rails, it is quite difficult to form a correct estimate of the average life of the same. Good iron rails have been known to last, in service on the main track of a railroad doing a fair business, nine or 10 years, and steel rails 15 to 20 years. There is much discussion on the subject of broken or even joints. The majority of track has heretofore been laid with even joints; but at the present time all rails are being laid with broken joints, which consists in placing the rail joint on one side of the track opposite to the centre of the rail on the other side of the track. Outside of the general line and surface the principal defects in steel rails are pipes, gag marks and cinders, which result in flaws. (See IRON AND STEEL, METALLOGRAPHY OF). Owing to heavy engines and cars of great weight now employed, heavy rails are demanded to be used and as the height gives vertical strength, in such heavy rails used, height should be the main consideration and should not be less than six inches. To give good wearing heads, the proportion of metal in the head should be kept down to the minimum, as owing to the present process of rolling steel rails at a great heat from a large ingot, a thick head will not give as good results as a thin head rail. The web should be thicker at the base than under the head, which in the high rail ensures greater strength, as the tendency is to break at this point, if too weak.

Wave Motion.—As all movements are on the principle of the lever, there is of necessity an undulatory motion on the passage of each train, the amount of which being dependent on the condition of the sub-grade, ballast, ties, rail and weight of the rolling stock. The less substantial the superstructure the greater ballast compression there will be, and, of necessity, a rough-riding track. The foundation of all ties being loosely compacted material, any movement or "churning" of the tie necessarily throws unequal loading on the ballast at different times, causes its compression and movement, and destruction of the tie foundation. The wider the ties and the lighter the rail and heavier the loads, the greater such movement must be. Rails take a permanent set, as regards wear motion, in one of three forms: (a) joint low and centre high; (b) joint and centre low, quarter high; (c) entire rail level. As the vibratory motion of the rail takes place something has to give way. If the fastening to the tie is by push bolt or lag screw, the tie will be raised with the vibration and "pump" the ballast, and in time the fastenings will become loose.

Elevation of Curves.—The elevation of curves has been a subject of much discussion. Thirty years ago one-half inch elevation per degree of curve was considered proper; but, now with faster and heavier trains a greater elevation is required. Engineers claim that one inch per degree for a speed of 60 miles per hour is proper for curves of three degrees or less, but for each additional degree the elevation should not exceed three-fourths inch. While practice teaches the amount of elevation needed in any given case it is a safer plan to

follow the ensuing formula deduced from mechanics in following the theory of elevation:

$$E = \frac{V^2 G}{32.16 R}, \text{ in which } E \text{ represents the elevation in feet, } V^2 \text{ the square of the velocity in feet per second, } G \text{ the gauge or the distance between the points supporting the wheel, or from the centre of one rail to the centre of the other, and } R \text{ the radius of the curve in feet.}$$

This rule, though scientifically correct, cannot always be applied in actual practice, because all trains do not travel at the same rate of speed. Practical provision must be made for the average speed of trains and the number in each class of service. For example, if a road have two trains whose speed is 50 miles per hour, four with a speed of 40, and six or eight with a speed of 25 miles per hour, one inch per degree of curve will be found suitable. The pressure by the fast train against the outer rail of a curve will not be sufficient to spread the rail or throw the track out of line. The elevation will be about right for the 40-mile trains, and while it may be excessive for the slow trains, yet they will do no particular damage to the track and will have a tendency to prevent the track being moved permanently outward by the fast trains. The liability of derailment of locomotives or cars is much greater on a curve track and a large percentage of such accidents is chargeable to the defects in the rolling stock as well as to the defects in the track itself. Heavily loaded cars often leave the track owing to the failure of a track to adjust itself to the curve of the track, caused, perhaps, by a defective curve roller, and the greater part of the load resting upon one side of the track.

Frogs and Switches.—The turnout, by which a car may pass from one track to another, consists of a frog, a rail leading to the

Frog.

frog, a corresponding opposite rail and a device connecting these rails with the main track known as the switch. If the switch is made to serve two turnouts, it is called a three-throw switch; a trailing switch is one where a train on the main track passes from frog to switch; while a facing switch is one that approaches in the opposite direction. The common or stub switch consists of a pair of connected rails so arranged that one end is fixed; the other can be moved so as to be a part of either the main track or turnout. This switch has two serious defects—the want of safety, and the necessary space at the end of the moving rail, which jars the rolling stock, batters the switch rails and causes discomfort to passengers. The first cost of a point switch is more than a stub, but the split, which is more economical to maintain and safer, is cheaper in the end. In laying switches the general rule is to cut the least number of rails. When putting frogs into a track care should be taken to have them in a true line and level with the track rails which are con-

nected to them. The gauge rail, opposite the frog, should be put to a perfect gauge for the full length of the frog.

Safety Appliances.—The greatest care must be exercised in the instalment of safety devices, as far as practicable automatic, without discouraging watchfulness on the part of engineers and others. The plan of sealing the stopping mechanism and imposing a severe penalty for breaking the seal is an excellent one. The most carefully planned automatic devices should be provided, and no railroad train, traveling at terrific speed, and representing enormous energy, should be allowed to run without any safeguard between itself and disaster beyond the watchfulness of one man, who may be taken ill, or suffer from a temporary mental aberration, or may even die suddenly and unnoticed.

Curving Rails.—Before any rail is spiked to its place in a curve it must be evenly bent from end to end, so that it will assure the proper curvature when lying free. This curving may be done by hammers, but that method is slow and the rail-curving machine is generally employed. This machine is made with either screw or hydraulic power, and is used for bending rails rather than for curving them. For many curves no rail-curving is necessary, the friction between the rail and the ties being

Rail Curving Machine.

sufficient to hold the rail in position. The extent of this flexibility depends on the weight and length of the rail, and can be found by trial. Three degrees and sharper curves usually require a curving of rails. Knowing the radius of the curve and the length of the rail, the *middle ordinate* of the rail can be taken from prepared tables. Each half of the rail, from the middle point to the ends, should also be tested for its middle ordinate to ensure uniform curvature. The middle ordinate of these half sections is one-fourth of the middle ordinate of the entire rail.

Grade Crossings.—The crossing of one railroad with another at grade is a common condition. This offers a dangerous condition which may be fully protected by a system of signals, derails, etc., which enables trains to proceed over the crossing at speed and with safety. The installation requires for a single line crossing eight signals, four of which are erected about 500 feet each way from the crossing. These four signals are called home signals. Beyond these, a distance of 1,500 feet or more, are located the distant signals. If we were certain that signals would be obeyed at

all times we would need no further protection; but we have not yet arrived at a degree of efficiency in discipline which ensures that trains will never run by a danger signal. It is the general practice in the United States to provide a derail at the home signal which is opened after all signals on the route are placed at stop. This derail is an ordinary switch point and if a train attempts to proceed to the crossing against a stop signal it is derailed. This seems a brutal method of compelling the observance of a signal. Experience has demonstrated, however, that the derail is a moral agent and is effective in its presence and is seldom called upon to perform its office. A clear signal cannot be given for the crossing until the derails on the opposite route are open, and the signals on that route are in the stop position and the signals cannot be pulled to the safe position on opposing routes.

The opening of a switch under a train is guarded against by the detector bar. A thin bar 55 or 60 feet long is hung in a vertical position on the outside of the rail at the switch point fixed on links clamped to the rail, and so arranged in the general scheme as to make it necessary for the operator to move this bar vertically above the rail before the switch can be unlocked or moved. If a car or train is standing on or passing over the points the bar cannot be moved because the wheels of the car prevent its rising above the rail, consequently the switch cannot be opened under the train. These bars are also provided on each side of the crossing so as to ensure against changing signals where a short or light locomotive may have passed the home signal toward the crossing but has not passed the crossing. This condition may be better protected by employing a track circuit between derails controlling an electric lock which ensures against change of signals until the train has passed entirely out of the limits of the derails. Where signals and switches are operated by lines of inch pipe carried on rollers and are compensated for change in temperature by what is known as a "lazy jack" these carriers, compensators and cranks are now usually fixed on concrete foundations.

Draw Bridges.—The protection of draw bridges is perhaps more important than grade crossings and for this work the interlocking machine is employed with the home and distant signals, and where practicable derails are used. The signal cabin may be located either over the pivot pier or on the shore. To ensure safety we must ensure that before a clear signal is given the rails at each end of the draw are down in place and locked, the draw itself locked to the abutment and the turning mechanism locked and that none of these conditions can be changed so long as the signal shows clear, and in reversing the order of movement the draw cannot be opened until the signals are at danger and the signals cannot be cleared until the draw is again closed, etc. The important device in this combination is the bridge coupler for pipe lines which must be uncoupled by the operator from the cabin before the draw is opened.

Surveys.—Surveys are location surveys and construction or final surveys. The instrumental location of a railroad does not differ materially from that described for a new wagon road, but greater accuracy is desirable, and a much

more careful adjustment of curves and grades is indispensable. As with common roads, the grade will mainly follow the natural surface, but the line must be so located as to keep these grades within the adopted limit, which will usually be 2 per cent, though in exceptional cases and for short grades 4 per cent is allowable.

Natural drainage lines present the most regular and easiest gradients, and in a broad sense it may be said that every railroad location follows lines of drainage. When the head or source of one drainage line is reached, the location crosses the divide to the next. With few exceptions, drainage lines have slopes not exceeding those permissible for railroad location. The first requisite in considering a railroad location is to get the lines of drainage clearly in the mind. This done, start the exploration from the initial point on a straight line for the objective.

Before the survey is started, the maximum grade and degree of curvature should be decided upon, and in surveying the line the instrument men will know what their limitations are and will locate the line accordingly. This maximum grade should be the compensated grade. This is, when the grade occurs on a curve, an allowance of .04 per cent of grade should be added to the actual grade for each degree of curvature to give the compensated grade. When the level man finds the grade running steeper than the limiting grade, he will take a sufficient amount of side notes to determine the amount of excavation or filling that will be necessary to keep the grade within the prescribed limits; and if he finds the amount of excavation excessive, he may have to call back the transit man and have the line relocated. This should not happen frequently as the transit man should know the maximum allowable angle of slope and should locate his line accordingly.

The virtual grade is the actual grade corrected to take advantage of the velocity head due to the speed of the train when the various grades are encountered. Its principal application is for economical construction, but even at moderate speeds it might occasionally permit the use of grades steeper than the so-called maximum. A pusher grade is an isolated case that cannot be kept down to the ruling grade nor compensated for by the velocity head. Here it is best to pass at once to nearly double the ruling grade and provide for a regular engine for that special grade. They should not occur oftener than once or twice in a division.

Roadbed.—The roadbed or the support for the track generally consists of the foundation and the ballast. The latter should be a material the consistency of which is not affected by water, and especially which does not become slippery when wet. Sand will do if nothing else can be had; gravel is better, and broken stone is the best of all. Cinders, shells, burnt clay and other materials are also used. The surface of the foundation on which the ballast rests is called the subgrade. Unless the natural ground is very unfavorable, it will not be necessary to use a separate material for ballast and the subgrade really disappears. Even then, the earth between and immediately under the ties which is dug into in surfacing the track is called

ballast. Such roads are usually called mud roads. The cross section of the roadbed must be decided upon before the level party starts on its work, in order that they may know the dimensions of the roadbed for which the stakes are to be set. The dimensions of the roadbed of a two foot six inch track would be, approximately, 11 feet from shoulder to shoulder on a fill and 10 feet from shoulder to shoulder in a cut. The dimensions for a track of three-foot gauge will be about 12 feet from shoulder to shoulder on an embankment and about 11 feet in a cut. In excavations, plenty of depth should be allowed for ditches in order to ensure a dry roadbed.

Wherever the grades permit, the track is laid directly on the surface of the ground, and the necessary leveling is done after the track has been laid.

Bridges.—The engineer in the field during wartime on coming to an opening where a bridge is required plans the bridge so that the openings between the abutments, or between bents of piles or trestles, shall be from the lengths previously agreed upon and for which the chief engineer is prepared to send material without delay. This classification can only apply to *single openings*, because with several spans it will be impossible to include anything general about the necessary piers. Only in exceptional cases will openings over 50 feet be provided for. Larger spans will be subdivided into spans of less than 50 feet by temporary piers wherever possible. In any stream the rate of the current and the amount of drift are important factors in determining the span to be used. The length of time a bridge will be in use is also important, as the river may be at such a stage that one length of span can be used, when if it were at a higher or lower stage an entirely different one would be necessary. On arriving at a bridge that has been destroyed, the first consideration is to get some sort of a line across to connect with the road on the other side. This can frequently be done by making a *deviation* which will carry the roadbed into the river bottom and up the other bank, necessitating only a very short, low bridge. This work is done by the advance party, and a second party follows and constructs the permanent bridge at the grade of the permanent track. Sharp curves on this diversion line should be avoided, since steep grades will be inevitable, and the combination may cause frequent derailments. Before the beams or trusses for the necessary spans can be decided upon, it is necessary to decide upon the location of the piers and abutments. The local conditions as to the banks and the bottom of the stream will, in general, determine the location and kind of abutments and piers that are to be used. In general terms, they will be either of piles, cribs or trestles.

Cableways.—In some places an overhead cableway can be used to great advantage in erecting or building a bridge or in transporting supplies across a stream that vehicles cannot cross. There are two classes, the *ordinary cableway* and the *balanced cable crane*. The first form can be quickly rigged if large trees are close to the bank and is very convenient when the load does not have to come in to the very foot of the supports. If towers must be

used to support the cable they are difficult to erect and the material is too heavy to carry in a field equipment. A considerably longer span is always necessary than the actual width of the stream and the load must be pulled up hill over one-half of its journey and is only stable at the lowest point in the catenary. The balanced cable crane, on the other hand, can carry loads farther inshore than its points of support; the stress in the cable is constant whatever the position of the load and only sufficient force to overcome friction is required to move the load along the cable. The key to the construction of this cableway is that the length of the cable must be such that *both* counterweights cannot rest on the ground at the same time. The automatic rising and falling of the counterweights as the position of the load on the cableway changes keeps the angles of the cable at the load symmetrical with the action line of gravity and hence the load at any point on the cable.

Turnouts and Crossovers.—A turnout is a curved track by means of which cars are moved from one track to another. The special parts of a turnout are the frog and the switch and the guard rails. The term "switch" is frequently applied to the part of a turnout from the point of switch to include the frog. The *switch proper* may be either a stub or a split switch. The latter is the form now generally used. Stub switches are only used on unimportant lines or in yards. A *double turnout* is one

Stub Switch.

where two tracks diverge from the main line, either on the same side or on opposite sides. In a turnout from a curve, the curvature of the turnout for a given frog is different from the curve of turnout from a tangent, and is equal to the curve of the main line plus the curve of the turnout from a tangent for a corresponding frog. The lengths of rail would not be exactly the same on the turnout from

Split Switch for Light Rails.

a curve as they would be on a turnout from a tangent. On account of this and because of the desirability of having a number of turnouts ready for use at any time, it is best to lo-

cate all turnouts on tangents, where practicable. These ready-made turnouts should include all material for the turnout, as shown in bill of material, so that by leaving out an exact number of 30-foot rails the track-laying can be continued; and when the turnout is put in place the opening left will be exactly filled. *Frogs* and *switches* can either be bought outright from equipment companies or can be made in the shops.

The curves used in laying out turnouts and crossovers are ordinarily arcs of circles and are usually simple curves. It may happen that no frog is at hand, in laying out a double turnout, that will permit a simple curve to be run from the heel of the switch to beyond the farthest frog. In this case, use the frog that will require the sharpest curve as the crotch frog, allowing the flatter curve to lie between the two frogs.

Facing and Trailing Points.—These terms apply particularly to the switches of crossovers on a double-track line. A trailing point is one

Facing and Trailing Points.

which the trains move over from the point of frog to the point of switch; and a facing point is one which the trains move over from the point of switch to the point of frog. A consideration of the drawing will show the advantage of trailing points, in that if the switch is set wrong the train will run through it, forcing the switch points aside. This will break the switch, but the train will not be damaged. On some roads the policy is to have all main-line switches trailing points and although this requires a little more time in switching cars or going into a siding, it is safer.

Switch Stands.—A switch stand is a mechanism by means of which the switch points are moved. The largest kind is more readily seen than the smallest one and would be used in cases where the engineman must be able to note a mis-setting of the switch. The smallest kind is the kind used in the interlocking plant, where it is next to impossible for a switch to be set wrong and the engineman not be notified of it long before he reaches the switch. The middle type is one that is commonly used in yards. Economy of space and weight might dictate the use of the smaller switch in all cases on a supply road. For *stub switches* these stands should be on the engineman's side approaching in a facing direction. For *split switches* they should be on the side of the turnout.

Storage Tracks.—The number and length of these tracks depend upon the importance of the station, the number of depot storehouses that may be located at that point, etc. A study of these items shows that each must be dealt with as it arises and as it is impossible to tell how important a station may become at any future time, available track room will be left

for additional loading platforms and storage tracks. In locating the storage tracks, room should be left between the various tracks so that

Classification of Locomotives by the number and disposition of their wheels: the larger circles represent drivers and the smaller ones truck wheels, the direction of forward motion being indicated by the cowcatcher.

at least one and preferably two lines of wagons can drive in and receive freight from cars on the storage tracks.

Tunnels.—Few serious difficulties are met in tunneling operations except in subaqueous work, where the nature of the soil is largely unknown, and the work may have to encounter faults in rocks or springs or quicksands in the earth; or the roof formed by a river bed may give way and tons of water may be precipitated into the workings below. Under these conditions work beneath the water has become a new science which has its own special class of workmen, tools and devices adapted practically for its own purposes as described elsewhere in this work under TUNNELS AND TUNNELING (q.v.). EDWARD S. FARROW,
Consulting Military and Civil Engineer.

RAILWAY LABOR ORGANIZATIONS, or RAILWAY BROTHERHOODS, labor unions formed by the employees of railways to advance their interests and promote their social, moral and intellectual

welfare. The larger and more typical railway labor organizations are distinguished for their generally conservative attitude, their large mutual benefit and insurance funds and their organization of grievance committees for arranging differences between their members and employers and avoiding strikes. As a rule they maintain pleasant relations with employers and have been instrumental in obtaining increased wages and general improvement in the condition of railway labor. The five most prominent organizations are the Grand International Brotherhood of Locomotive Engineers, the Order of Railroad Conductors, the Brotherhood of Locomotive Firemen, the Brotherhood of Railway Trainmen and the Brotherhood of Railroad Telegraphers. These five have the same general form of organization, with the supreme power in the central representative body called the Grand Lodge or Grand Division, meeting in convention every two years, and the executive power vested in a chief executive (grand master or grand president) and an executive board. Their subordinate divisions include locals and section divisions, the latter made up of the employees of one railway line or system. Their provisions for dealing with grievances against employers are as follows: Any member or members having a grievance against an employer are to report the same to their local organization, which, in case the majority vote to sustain the grievance, shall refer it to a local grievance committee. This committee is to deal with the local management, and should no satisfactory settlement be made, refer the grievance to the general grievance committee of the section, who shall confer with the general manager of the railway system. Then, if no adjustment be made, the matter is to be referred to the chief executive of the union who shall make another attempt to adjust the matter with the employers, and, if he fail, he and the general committee shall have power to sanction a strike, provided a strike is agreed upon by two-thirds of the members involved. In some cases a board of adjustment is formed by the chairmen of three or more general committees, in which case the matter is to be referred to this board before going to the chief executive. It will be seen that this arrangement makes a strike difficult to bring about and prevents strikes for trivial causes, yet all of these unions have established large protective or strike funds for the benefit of members when on strike. Another feature of these organizations is the legislative board, organized in each State by representatives from each local for the consideration of questions of legislation affecting their unions; and these boards have power to appoint one or two members to remain at the State capital for securing desired legislation. A ladies' auxiliary is affiliated with each brotherhood. A home is maintained at Highland, Ill., for aged and disabled railroad employees.

The Five Larger Brotherhoods.—(1) The Brotherhood of Locomotive Engineers was organized in 1863. The locals have sick and death benefit funds and the Brotherhood has a fund for pensioning widows and children of the deceased. The insurance is under the management of an affiliated organization known as the Locomotive Engineers Mutual Life and Accident Insurance Association. The Brotherhood

number 73,800 members in over 600 locals. The official journal is the *Journal of the Brotherhood of Locomotive Engineers*, published monthly. It ranks among the most important and influential labor organizations of the United States and is noted for its conservatism. (2) The Order of Railway Conductors was organized in 1868 as the Conductors' Brotherhood, was threatened with serious difficulty on account of its prohibition of strikes and a rival union started which had a "protective" policy, the Order adopted the same policy, established its "protective" fund, and the two organizations were united under the present name. It has a mutual benefit fund and the strike fund provides for payment to strikers for not over three months. The official journal is the *Railway Conductor*, published monthly. The membership is 49,100 in about 500 locals. (3) The Brotherhood of Locomotive Firemen was organized in 1873, was involved in the great strike of 1877 and seriously crippled; for a time it adopted the policy of "ignoring" strikes, but in 1885 returned to its original policy and methods in dealing with strikes; and a few years later conducted a large strike on the Chicago, Burlington and Quincy Railroad. Strikers are paid for three months or less. The official journal is the *Locomotive Firemen's Magazine*. The membership is 86,800. (4) The Brotherhood of Railroad Trainmen was organized in September 1883 and admits to membership conductors, baggagemen, yardmasters and switchmen besides trainmen. They have a sick and death benefit fund and a strike fund, providing for a payment to strikers for three months or less. It has 126,100 members; its official organ is the *Railroad Trainmen's Journal*. (5) The Order of Railroad Telegraphers was organized in 1886; its membership includes telegraphers, line repairers, levermen and interlockers. Its mutual benefit fund was established in 1898; it has never held quite the same position of importance as the other four brotherhoods, as at the first it grew more slowly because the telegraphers are scattered and it is difficult to get any number together, but since 1900 has grown rapidly. It numbers about 30,000; its official journal is the *Railroad Telegrapher*.

The Union of All Railway Employees.—Though these brotherhoods have much in common in organization and purpose there has been rivalry and discord among them, which has proved decidedly detrimental to their best interests. In 1895 an alliance between the five brotherhoods was formed, providing for the formation of a federated board of adjustment for the consideration of grievances and management of strikes. A more centralized federation was organized in 1898, but dissolved in 1900, leaving the agreement of 1895 in force. The first attempt to form a union which should unite in one organization all classes of railway employees was the American Railway Union, organized in the early part of 1893 by Eugene Victor Debs. This union lacked the complicated organization of the older brotherhoods, was radical and aggressive and met with bitter opposition from the older unions. It drew away some of their membership and grew rapidly; before the close of the year it conducted successfully a strike against the Great Northern Railroad.

In 1894 it inaugurated a sympathetic strike in behalf of the Pullman Car Company employees, was defeated and shortly afterward the organization dissolved. A later attempt to unite all railway employees is the United Brotherhood of Railway Employees, organized in January 1901, which also resulted in failure.

Lesser Organizations.—Of the smaller organizations those which closely resemble the five larger brotherhoods in organization are: (1) The International Brotherhood of Maintenance-of-Way Employees, organized in 1887 as the Brotherhood of Railway Trackmen; its membership includes those employed in track, bridge and building, water supply and fuel departments and signal and interlocking service; it has a mutual benefit department and the same provisions for preventing strikes and dealing with grievances as the other brotherhoods; the official journal is the *Advance Advocate*; the membership is about 10,000. (2) The Switchmen's Union of North America, organized in 1894, admits to membership those engaged in making up and disposing of trains. It has a beneficiary department, membership in which is compulsory for those physically sound. The organization is the same as in other brotherhoods. The membership in 1914 was 9,800; this is less than it would otherwise be because of the fact that the Brotherhood of Railroad Trainmen, an older and more powerful organization, also admits switchmen. The official organ is the *Journal of the Switchmen's Union*. (3) The Brotherhood of Railway Carmen, organized in 1900 by a consolidation of the Brotherhood Car Repairers of North America and the Carmen's Mutual Aid Association. Its membership consists of those who are employed in oiling, repairing, inspecting and cleaning cars; it is a comparatively unimportant organization. (4) The National Railways Clerks' Association, organized in 1901, had in 1914 a membership of 5,000 in about 50 locals; it publishes the *Official Journal of the N. R. C. A.* (5) The International Association of Car Workers, organized in 1901, includes in its membership those employed in the construction and maintenance of all cars; it has no benefit department, but the arrangement for dealing with grievances and strikes by local and general grievance committees; its declaration of principles is conservative, including opposition to prison contract labor and a declaration in favor of reduction of hours of work and compulsory education. Its official journal is the *Car Worker*; its membership is over 20,000.

Other railway organizations are the Mechanical Trackmen, with 4,000 members; the Railroad Freight Handlers, with 3,000 members; Railroad Signalmen, with 11,000 members; Railroad Station Agents, with 11,000 members; Railroad Station Employees, with 4,300 members; Railway Express Messengers, and Railway Expressmen, and the Street and Electric Railway Employees, with 54,500. According to the *Quarterly Journal of Economics* there are about 600,000 members enrolled in the several railroad labor organizations. Consult *Review of Reviews* (May 1917); *Quarterly Journal of Economics* (passim) and publications of the Bureau of Labor Statistics of the United States Department of Labor. Consult also files of the official brotherhood journals mentioned above.

RAILWAY SHOPS AND MACHINERY. Railway buildings and machinery are required for the maintenance and repair of locomotives and cars and for their cleaning, inspection and storage. Few railways build locomotives on a large scale, although their engineers design them. Many railways build freight cars and sometimes passenger cars, but both cars and locomotives are built mainly by private firms. See RAILWAY CARS; LOCOMOTIVE.

Repair work, however, must be done by every railway. Usually there is one main shop plant where engines are sent for extensive repair or rebuilding. There may be more than one, but the tendency is to concentrate the heaviest work, this being economical in time and cost and in machinery investment. Important division plants will have shops for general repairs, and at the ends of all operating divisions there will be facilities for such light repairs as are needed to keep the equipment in service. Economic use of engines and cars requires that they be kept in good condition, so that they may give the greatest mileage and service before they need be sent to the shops for extensive overhauling and repair. The plan and facilities at any shop plant will vary with its capacity, its site, its special purposes and the ideas of the designers. Provision must be made for future enlargement.

A large repair plant for locomotives will include a machine shop, erecting shop, boiler shop, tank—or tender—and sheet iron shop, iron foundry, pattern store and supply storehouse. The first five of these may be separate or grouped in two or more large buildings. The erecting shop, where the engines stand while being dismantled, repaired and assembled, may have several short transverse tracks for one or two engines each, or a few widely-spaced longitudinal tracks. To avoid blocking these latter, the engines may be lifted from their wheels and placed on the floor between or outside of the tracks. Pits in the tracks enable workmen to get under the engines.

Overhead traveling cranes shift the locomotives. With the longitudinal plan, two cranes of 100 to 150 tons capacity must be used, one at each end of the engine. With the transverse plan one 200 to 250-ton crane can do the work. Similar but lighter cranes at a lower elevation may handle the various parts and materials. Less expensive arrangements for division shops, to permit of removing the wheels, are power-operated screw jacks which lift the engine by beams under its ends, or drop pits beneath the tracks for small carrying hydraulic jacks which take the wheels from under the engines.

Longitudinal tracks extend through the building to yard connections, but the short transverse tracks extend usually through one side to the pit of a power-operated transfer table which has one track and travels laterally so as to connect this with any one of the tracks leading to the pit. Usually two buildings are on opposite sides of the transfer table, each with room for an engine to stand between it and the pit.

A large repair plant for car equipment will include a coach or passenger-car repair and erecting shop, coach paint shop, coach truck shop, freight-car repair shop, cabinet shop, woodworking shop and outdoor repair tracks.

Also a lumber yard and dry kiln. A blacksmith shop and machine shop are required, but in a combination plant these—and the foundry—may serve both the locomotive and car shops. Brass and steel castings are generally purchased.

Passenger car shops generally have short transverse tracks served by an outside transfer table, running between two buildings. Freight car repair work of the heavier class may be done in a building equipped with overhead cranes, but much ordinary repair is done on open tracks. These are arranged in pairs, the alternate wide spaces admitting intermediate tracks for trucks carrying materials. The repair yard has pipes supplying water for refrigerator cars and compressed air for testing brakes and operating tools.

Shop buildings are usually one-story structures, except that in the machine shop the lighter work may be done on a mezzanine floor at the side. Storehouses and pattern stores are usually several stories high. Modern buildings are largely of steel frame or reinforced-concrete, with large window areas of steel sash, and with monitor or saw-tooth roofs for light and ventilation. A power-house furnishes steam heat, water, compressed air and electric current for light and power, although electric supply is often obtained from an outside source. Machine tools and other appliances are operated largely by electric motors. Auxiliary to the plant will be its water supply and sewerage, heat, light and power, sanitation and locker and wash-rooms for the workmen. Handling material between the several shops and departments may be effected by motor trucks, narrow gauge railways or small tractors hauling trailers on paved roadways.

Locomotives operate over fixed divisions, between certain points, the distance averaging 100 miles. At each end must be an engine terminal with facilities for cleaning the fire, supplying coal and water, inspecting and cleaning the engine and making light repairs, and turning it for the return trip. Coal and water supply must be provided also at points along the division.

An engine which has just brought in a train and finished its trip goes to the engine terminal where it takes water and coal if necessary and then has its fire cleaned or dropped at an ashpit. If not at once sent to an outbound track it is moved to the engine-house to be inspected and cleaned and given light repairs, especially those reported by the enginemen. Inspection is done sometimes at a pit in advance of the ashpit. The engine is held in the house until assigned for the return trip, when a new fire is lighted. Where no repairs are necessary, engines ready for service may be stored on outdoor parking tracks arranged radially or parallel. An engine going out to its train usually takes coal, water and sand just before leaving, so that facilities must be accessible to both inbound and outbound engines. Other facilities include machine shop, storehouse, sand drier and oil house. Also a rest room for the men, with quarters for engine crews whose homes are elsewhere.

Engine-houses on American railways are usually of the "roundhouse" type, being segmental in plan, with radial tracks converging upon a turntable by which an engine can be

transferred from any radial track to the approach track connecting the turntable with the yard tracks. Rectangular houses are used in some cases, with parallel tracks connected directly to an approach track or served by a transfer table traveling at right angles to them. A special design has short diagonal tracks opening from a track extending along one side of the building. A turntable is like a revolving bridge and serves both to shift and turn locomotives. If this is not provided there must be a Y-track, forming a triangle, for turning engines and cars. In Europe, engine-houses are generally rectangular with tracks parallel or radiating from a turntable inside the building. To provide against blockades there should be more than one track leading to the turntable.

Roundhouses rarely form a complete circle. They are of brick or concrete, with low roof, and have either double swinging doors or flexible steel doors that roll up at the top. To carry off the smoke, especially when new fires are being started, each engine stands with its smokestack under a smokejack or hood, which extends through the roof. To avoid a nuisance, the smokejacks may be connected to a flue served by an exhaust fan and led to a tall chimney or to a series of water-filled trays through which the gases rise and are discharged to the chimney while soot and dirt are retained. In such cases the smokestacks are lowered into contact with the engine smokestacks. A pit between the rails of each track permits men to go under the engines to inspect and repair them. Frequently a drop pit is provided for a truck with jack to take an axle and pair of wheels from under the engine. The machine shop is usually an annex to the engine-house and sometimes one of the radial tracks extends into this shop.

Water stations comprise mainly a pumping plant with elevated tank which may supply the engines directly by spouts or may distribute a gravity supply to water columns. These are tall stands having a horizontal pipe at the top, the latter capable of being swung across the tender of an engine and discharging into the tank. When not in use this pipe lies parallel with the tracks. Water that is hard or of scale-producing quality may be treated in a chemical plant before going to the elevated tank, this being far preferable to the practice of putting chemicals in the tender or boiler. Track tanks for supplying water to moving locomotives were invented by John Ramsbottom, of England, in 1861 and are used on a number of main lines in the United States. The tank is a shallow pan about 20 to 24 inches wide and seven inches deep, laid upon the ties for a distance of 1,200 to 1,500 feet and provided with steam and circulating pipes to prevent freezing. A hinged pipe on the tender is lowered so that its mouth or scoop dips below the surface. The speed of the train causes the water to be driven up this pipe, which ends in an elbow discharging the water downward into the tender tank.

Coal is delivered to the engine tenders in various ways. Buggies or cars loaded by hand may be wheeled over a platform alongside the coaling track and above the level of the top of the tender, or they may be wheeled on a bridge spanning the tracks and having hinged spouts to be lowered to the tenders. Locomotive cranes with grab buckets may deliver coal from

the stock pile to the tender. The most general method is to place the coal in elevated bins fitted with hinged spouts, the bin being either parallel with or across the tracks. For loading the bins, coal cars may be pushed up an incline by a locomotive or pulled up a steeper incline by a cable hoist. In many cases the cars dump the coal into a hopper beneath the track, whence it is fed to an intermittent vertical bucket elevator or a continuous conveyor which delivers it into the bin.

Where oil fuel is used, special tanks, pipes and oil columns are required to supply the tender tanks. Economy demands that fuel delivered to each engine should be weighed or measured and recorded, and special automatic apparatus for this purpose is in use.

Ashpits where locomotives have their fires cleaned consist frequently of two parallel shallow pits—under the engine tracks—with a deeper pit between them for a car into which the ashes are shoveled or sluiced. The ashes may be dropped directly into small steel cars standing in deeper pits under the engine tracks, these being pulled out on an incline at the end or side of the pit; or with a pit transverse to the tracks the engines may drop the ashes into fixed steel hoppers from which they are discharged at convenient times into a small car running on the floor of the pit. This car is hoisted out and emptied by a crane at one end of the pit. Another plan is to put the engine tracks over the sides of a Y-shaped pit, the ashes sliding down into the deep part, which is full of water. The pit is cleaned by a grab bucket handled by a gantry or locomotive crane.

Cleaning passenger cars is provided for at terminals on groups of tracks usually connected at one end only, but sometimes at both ends. Wide spacing affords room for operations, and permanent staging may support the cleaners' platforms. The yard is paved and drained. Pipes with hose connections at intervals supply water for washing, steam for heating, compressed air for charging brakes; and sometimes there are pipes for vacuum cleaners, as well as electric connections for lighting cars and charging batteries.

RAILWAYS, American Street. See AMERICAN STREET RAILWAYS.

RAILWAYS, Elevated. Elevated railways presented one of the first potent factors for the solution of the problem of adequate transportation for passengers between points in great cities. The street railway was an earlier factor, but it met the growing inconvenience of congested streets in only a partial degree, affording but temporary relief. In New York, which city possesses the most extensive system of elevated railways in the world, without taking account of the large system in Brooklyn,

now a part of the greater city, two means of relieving the streets of some of the burden of passenger traffic began to be considered as long ago as 1860. Two possible solutions presented themselves, one being to carry it underground through tunnels, and the other to carry it over elevated structures. The former met with more favor at the outset, but the first underground project undertaken was speedily abandoned. Considerable ridicule was expended upon the other idea, but in spite of it an elevated railway, with a single track, was built from Battery place through Greenwich street and Ninth avenue to 30th street in 1866 and 1867, and opened to travel on 2 July 1867. It was operated by means of a cable for a short time, when steam locomotives were substituted as motive power. It did not gain popularity as an aid to local travel, and its lack of success caused it to pass into the hands of the sheriff in foreclosure proceedings, and it was sold for the benefit of creditors in 1871.

The West Side Elevated Railroad Company, as the corporation which built and operated this pioneer elevated line was named, was succeeded by the New York Elevated Railroad Company, organized 3 Jan. 1872, under a charter granted by the State legislature the year before. A few months later, on 17 June, the Gilbert Elevated Railroad Company, which obtained a charter earlier in that year, was organized to build a line projected by Dr. Rufus H. Gilbert, and which was planned to be a pneumatic tube railway, suspended from lofty arches. For some reason the pneumatic tube idea was abandoned, sustaining at first a modification which, by cutting off the upper half of the tube, made it a mere trough wherein the cars were to run, and it was decided to build a simple elevated railway. Meanwhile there had been not only lack of encouragement for this sort of enterprise, the West Side experiment not having succeeded yet in overcoming popular prejudice, but there was antagonism on the part of property owners who would be affected by the construction of such railways, and there was friction also between the two existing companies. Litigation assisted to complicate and delay matters.

This was the condition of affairs when, in 1875, the State legislature passed what is known as the Husted Act, which provided for a commission to decide as to the necessity for an elevated railway system in New York City, and to determine proper routes. Under this act a commission was appointed by the mayor of the city on 1 July 1875, and after a number of hearings given to all who favored or opposed such a system the decision arrived at was a favorable one. The commissioners announced on 11 December that their work was ended, the routes which they selected being four in number and including respectively Ninth, Sixth, Third and Second avenues. The work of building the lines was assigned to the two companies then existing, and both companies entered at once upon active construction and into equally active litigation, while each was under the necessity of defending the constitutionality of its charter against the attack of citizens, who were determinedly opposed to both. The New York Elevated had extended its line from the South Ferry to 61st street and Ninth avenue in 1876, and had opened it for travel to 59th street.

About this time the enterprise enlisted the interest of Cyrus W. Field, who secured a controlling interest in the company in the spring of 1877. The same vigor and determination that marked his connection with the first Atlantic Telegraph Cable was displayed here, and much of the credit for the eventual success which attended the new departure in urban passenger traffic was accorded to him.

Rivalry between the two existing companies had created much business for the courts in the meantime; the constitutionality of their charters was questioned; and there were injunctions and counter-injunctions. The Court of Appeals finally was asked to pass upon the constitutionality of the charters, and it sustained them both by a decision which was unanimous. All injunctions were dissolved and work was pushed forward, not only on the pioneer West Side line, but also upon the Sixth avenue line, which had passed from Dr. Gilbert's control and was known now as the Metropolitan Elevated Road. This line, extending from Rector street to 59th street, was opened 5 June 1878. During 1879 the New York Elevated opened its West Side line to 83d street and constructed its Third avenue line which was opened to 129th street the same year. By this time the new means of travel within the city had commended itself to popular favor to such a degree that the permanency of the enterprise was assured. The Manhattan Elevated Railway Company, organized under a Rapid Transit Act, passed in 1875, and chartered on 29 December of that year, took a lease of the roads owned by both the New York Elevated and the Metropolitan, the lease dating from 1 Feb. 1879. From that time the entire elevated system of New York City, of course not including the Brooklyn system, was known as the Manhattan Elevated Railway. In 1880 the Ninth avenue line was opened to 155th street; a spur from Chatham square created an additional terminus for the Third avenue line at city hall; a branch of the same line at 34th street afforded connection with the Second avenue line, which it crosses below grade, and gave access to the Long Island City Ferry from both lines; and a branch from the Third avenue line at 42d street connected with the Grand Central Railway Station.

Financial difficulties which had repeatedly beset the companies which had undertaken the development of this already gigantic project were of such magnitude in 1881 that the Manhattan went into the hands of receivers on 14 July. After the difficulties had been straightened out and a reorganization of the company had been effected, each year was marked by extension and improvement of the service until the system became, in 1904, an elevated railway consisting of four main lines with branches, its total trackage being 117.14 miles, divided as follows: Main lines and branches, two tracks (each 37.68 miles), 75.36 miles; third track, used for express trains, 15.19 miles; sidings, 26.59 miles. The southern terminus of all the lines was at South Ferry. The Sixth and Ninth avenue lines ran through Battery Park to Greenwich street, diverging at Morris street, whence the Sixth avenue line extended through Church street to Murray street, through which it reached West Broadway; it traversed this thoroughfare to 3d street, passed through 3d

street to Sixth avenue, which it followed to its terminus at 59th street, the station being at 58th. A branch running westward through 53d street connected it with the Ninth avenue line. From Morris street the Ninth avenue line ran through Greenwich street to Ninth avenue and through that avenue to 110th street, where a double curve on a very high structure carried it into Eighth avenue, which it followed to the terminus at 155th street. The Second and Third avenue lines were one from South Ferry to Chatham square. After leaving the ferry they made a sharp turn into Front street; thence through Coenties slip and Hanover square they entered Pearl street, which they followed to and through the New Bowery to Chatham square. They diverged here, the Third avenue line continuing through the Bowery and Third avenue to the Harlem River. At 34th street passengers desiring to reach the Long Island Ferry transferred to a "shuttle" train; and at 42d street another "shuttle" train conveyed transfer passengers to the Grand Central station. Trains from city hall followed the same line, and passengers were transferred at Chatham square to the Second avenue line if they desired it, as well as at the two other transfer stations mentioned. From 129th street at the Harlem River the Third avenue line continued northward, crossing the river by a fine bridge, open also to foot passengers. North of the river the line ran over a private right of way to Third avenue at East 148th street, whence it followed the avenue to Pelham avenue in Fordham, opposite the entrance to Saint John's College. Pelham avenue was practically the end of the line, but from this point there was an extension to the Botanical Gardens in Bronx Park, about a half mile farther north. The Second avenue line, after leaving Chatham square, passed through Division, Allen and East 23d streets to Second avenue, through which it continued to the terminus at 129th street and the Harlem River, where passengers going further north transferred to the Third avenue line. Transfers were made at 34th street to either the Long Island Ferry or the Third avenue line via the branch operated on that street. Down-town passengers on either the East or West Side were transferred at South Ferry to up-town trains on the other side. There was also a system of transfers to the surface lines at various points, the transfer costing the passenger three cents extra.

Until 1901 steam locomotives were relied upon entirely for motive power. The matter of substituting electricity began to be agitated in 1885. The first experiments were made with a motor invented by Leo Daft which was kept in service intermittently on the Ninth avenue line, between 14th and 50th streets, from 27 Aug. 1885, until 19 October, when a series of carefully recorded daily runs was made, continuing, except on Sundays and election day, until 22 December. The object of this series of runs was to ascertain measurement of coal consumed, etc. The Daft motor derived its power from an insulated third rail. It did not commend itself to the management of the road, and the inventor was unable to make such improvement in it as to secure its adoption. During the latter part of 1886 F. J. Springer operated an electric car successfully on the 34th street branch; and in 1893 an electric locomotive

designed by J. B. Enty which was operated by current derived from storage battery, or from a third rail, as might be found necessary, was tried on the same branch with excellent results, but neither of these inventions was regarded as wholly satisfactory. While New York led in adopting elevated railways, it permitted Liverpool to be the first in adopting electricity as motive power, the Liverpool Overhead Railway, completed in 1893, adopting it at the outset. In the same year the Intermural Railway, a feature of the Columbian Exposition at Chicago, made successful use of electricity in the operation of its cars. It was not until the spring of 1899 that the Manhattan Railway decided to use electricity, and the change from steam as motive power was made gradually, the first trains operated by electricity being run over the Third avenue line in 1901. It had already come into use on the elevated railways in Brooklyn. The number of passengers carried over the system in 1904 averaged 700,000 daily. The system went under lease to a corporation named the Interborough Railway Company, chartered 6 May 1902.

Brooklyn, one of the boroughs of New York City, had in 1904 an extensive elevated railway system which, like that in Manhattan and the Bronx, grew out of independent enterprises which finally consolidated. The first company was chartered 26 May 1874, under the somewhat peculiar name of the Brooklyn Elevated Silent-Safety Railway, afterward changed to the Brooklyn Elevated Railway. It encountered vicissitudes, chiefly financial, and was reorganized 29 May 1884. Other companies were chartered prior to the date last mentioned, and several later. The Brooklyn Union Elevated Railroad was chartered 30 Jan. 1899, to take over the properties of the Brooklyn Elevated, the Union Elevated and the Seaside and Brooklyn Bridge Elevated railroads. On 7 July, in the same year, the Kings County Elevated Railroad was chartered to succeed an earlier company of similar name. This company was reorganized in July 1899, absorbing the Fulton Elevated Railway. Early in May 1900 this company acquired the Sea View Railroad, and subsequently it and its acquisitions were merged in the Brooklyn Union Railroad, which was a part of the entire system of elevated and surface lines operated by the Brooklyn Rapid Transit Corporation. The first elevated line in Brooklyn was opened in May 1885. The various lines comprised in the system had termini at Fulton Ferry, the New York and Brooklyn Bridge, the Broadway Ferry, the Williamsburgh Bridge, Ridgewood, East New York, Woodhaven (where trains followed the New York and Rockaway Beach Railroad to Rockaway), and at 65th street, Bay Ridge. All trains to and from the bridge either traversed the full length of the bridge to New York, or transferred there to the bridge trains, which were operated formerly by the bridge authorities. The same conditions exist in regard to trains arriving at or leaving the Williamsburgh bridge. The total length of all the elevated lines in 1904 in Brooklyn was 28.70 miles, with a total trackage of 67.82 miles. Electricity was introduced as motive power in July 1900.

Chicago opened its first elevated railway in October 1893, the pioneer company being the Lake Street Elevated Railway, chartered 24

Aug. 1892. Other companies were subsequently organized, and there was, as in New York and Brooklyn, a series of reorganizations and consolidations which gave to the city a large and convenient system, operated by electricity.

Boston also had a fine system, which from its opening was operated by electricity. The building of an elevated railway system was discussed in Boston as early as 1876, but popular opposition and business interests combined successfully for years to defeat any action by the State legislature, which alone was competent to give the necessary authority. The Boston Elevated Railway Company obtained a charter, finally, in 1894, and the road, which was opened 10 June 1901, was constructed in a little over two years. Its total length was about six and two-thirds miles, and the total trackage, including sidings, was something over 16 miles.

The total of 308.94 miles of elevated track in 1902 has gradually increased to 429.67 miles in 1918, electricity being the motive power, with the exception of about 16 miles operated by gasoline motors. The present car equipment of the elevated roads in operation is relatively large, averaging about 12 cars per mile of track, and has kept pace in all general improvements with the surface and subway equipment. As a rule the car body is built throughout with structural steel and pressed steel shapes, and is designed with continuous structural steel centre sills and plate side girders. The floor and side framing is designed to in-

The recent introduction of field control with the interpole motors has become a most positive power saver. This is simply a revival of the old control system used in some of the earliest railway motors. The early double-reduction motor made the most extensive use of this, since the control was entirely by commutating the field and employed no external resistance at all. It was used to a greater or less degree in these motors and in some of the single-reduction motors as well. This system worked with marked success in its application on the locomotives of the New York, New Haven and Hartford Railroad. These had single-phase motors of the series-compensated type, which permitted a wide range of variation in the field strength without impairment of the commutation.

In elevated and subway construction the great advantage of heavier rails lies in their increased conductance which tends to render unnecessary a paralleling feeder system. The length of rail used affects the labor of handling and the number of bonds necessary to a large extent. The present practice of bonding presents no particular difficulty where third rails are properly supported and anchored. There has been much experimental work conducted with new and original sections for use as third rail. The chief considerations which led to these were (1) to produce a section which had a greater contact surface in proportion to its weight than the ordinary T-rail, thus giving a greater wearing surface and longer

Different Third-rail Sections.

clude cross-bearers which transfer the floor load to the side trusses. The entire car body, exterior and interior, is made fireproof and is thoroughly insulated against extremes of heat and cold, noise and the effect of vibration. In the latest pattern, an important feature of the underframing is contained in the body bolsters. These are made of two soft-steel plates with a cast steel separator in the centre. The steel casting, in addition to serving as a separator for the top and bottom plates, is designed to form a housing for the draft springs by extending it beyond the bolsters toward the end of the car body. Each bolster is equipped with a roller side bearing.

life, and (2) to obtain a section which could be more easily supported and which would provide greater facility for bonding, anchoring, insulating, etc., than the ordinary T-rail. The drawing shows a number of third-rail sections. The section shown at A is the 80-pound standard T-rail section commonly used. B is a special section used by the Long Island Railroad. C is a similar section used by the New York Municipal Railway. All of these are used for over-running contact. The section shown at D is that used by the New York Central Railroad on rails with under-running contact. It was designed to provide a better support for this type of construction than was available

with the standard T-section. Section E is that of the Philadelphia and Western Railway, which was originally designed as an under-running rail, but has since been inverted, a change which was found necessary to meet local conditions. The remaining sections shown, F, G, H, K, L, M, O, are special types for over-running third rail, and special shapes brought out to provide a more satisfactory means for supporting these sections and also for supporting a protective covering.

Consulting Military and Civil Engineer.

RAILWAYS, Government Control of. The government's obligation to maintain an equitable relationship between the public and carriers is a continuing one, although the problem has assumed a different form from time to time and is merged to some extent with the problems of the public control of corporations. In enacting the Sherman Anti-trust Law, Congress had only industrial combinations in view; but the rulings of the Supreme Court have made the law an important part of the legislation for the regulation of railroads. As a measure for the control of inter-railway relations the law is faulty in that it makes practically all co-operative action on the part of rival carriers illegal. While the Sherman Act and subsequent legislation have fixed the general scope of the governmental regulation of transportation, the efficiency of governmental control has been determined by the actions of the courts in interpreting the law and in exercising their equity powers.

To understand the fine distinction between *government control of railroads* and *government ownership of railroads*, a study or examination of the *Railroad Control Law* will greatly assist. This law, enacted in March 1918, authorized the President to contract with the companies for the payment of an annual sum not exceeding a specified maximum, to be determined for each road by the average annual railway operating income during the three years ending 30 June 1917. The government agreed to pay all taxes, State or Federal, assessed during the period of Federal control, except the excess profits tax and the corporate income tax. These latter were to be paid by the company out of the payments made to it by the government. With respect to the effect of government control on State taxation of the railroads, the act expressly provided that it should not affect "existing laws or powers of the States in relation to taxation." The President was authorized to initiate rates, but they were required, to be "reasonable and just" and they were subject to review by the Interstate Commerce Commission. The act directed the commission to consider when reviewing the President's rates the circumstances caused by war conditions and the need for additional railroad revenues. Federal control was to continue during the war and not exceeding one year and nine months after the ratification of the treaty of peace. Congress authorized the government to take control of street and interurban railroads necessary for the transportation of ship yard employees.

Among the most important of the needs of the situation is the compulsory Federal incorporation of railroad carriers. So long as Con-

gress confined itself to restrictive legislation of railroads as *common carriers*, it was not material whether they were Federal or State corporations, or indeed corporations at all. The working and operation of the physical properties and their relations as carriers to the public were the only matters of concern, and their corporate functions were not substantially affected. If only restrictive and oppressive legislation were intended now, Federal incorporation would not be necessary. But the time seems to have arrived for a comprehensive legislative plan for developing and sustaining necessary railroad transportation, or, in other words, for *constructive legislation*. The present system of regulation now imposes on the Interstate Commerce Commission, executive, judicial and legislative functions of great difficulty and importance, and all plans thus far suggested contemplate enormous additions to such functions. This commission should be relieved of its executive duties, for which such a body is least suited.

It is obvious that executive and administrative functions cannot be efficiently exercised by boards, commissions or committees. This was demonstrated during the European War. The larger the board or commission, the more cumbersome or difficult becomes the task. Experience has demonstrated the necessity for a national government officer to meet emergencies resulting from exceptional congestion in traffic or through blockades of transportation, by quickly mobilizing the transportation resources, and by the arbitrary diversion, if need be, of traffic from lines which cannot handle it to lines which can, and by other instant and heroic methods. It is generally conceded that there should be a *Transportation Department* of the government with a Cabinet member at its head in order that railroad business might be properly represented and have a "friend at court." In the matter of service, a Cabinet officer by calling in railroad executives and through informal discussions could bring about changes in train service, schedules and other things desired by the public, which if taken up with the elaborate formality and procedure inevitable in cases of a commission or similar body would not be accomplished for weeks or months. A single executive representing the government in all these important matters of service could get into instant touch with the railroad executives and secure action with respect to these matters of such vital importance to the public very much quicker than would be possible by the slow-moving procedure of any board or commission. The secretary would not be hemmed about by any judicial conceptions and matters of importance could be promptly brought before the Interstate Commerce Commission by formal complaint. The largest single industry in the United States, next to agriculture, and certainly there is none more vital to the very life of the nation, has, it will be seen, no department, bureau, agency or officer of any kind or description whose duty it is to look after its interests, to defend it or to say a word for justice in its behalf. The Interstate Commerce Commission was conceived in hostility to it and the Interstate Commerce Act was designed to repress, regulate and punish it. The figures given out by the United States Railroad Administration, giving the results of government

control during the European War, show that 5,377,468 soldiers were transported in 14 months on American railroads, 7,173 special trains, carrying 95,246 cars, being operated. The Overman Act, approved 21 March 1918, provided that the Interstate Commerce Commission should ascertain and certify to the President the average annual railway operating income to be used by the President in making agreements for compensation for the use of the transportation systems of the country. In case the amount of compensation was not adjusted, claims could be submitted to boards of referees appointed by the commission, and the finding of such boards would be a maximum of compensation which would be paid to the carriers. See RAILWAYS, GOVERNMENT OWNERSHIP OF.

EDWARD S. FARROW,

Consulting Military and Civil Engineer.

RAILWAYS, Government Ownership of.

Since the World War began in Europe, conditions have made it impossible to compile complete statistics regarding the railroads of the world. However, with the knowledge we have regarding the extent of government ownership before the war, and regarding the changes in the relations between the railways and the state which we know have occurred since the war began, it is possible to give an approximately correct idea of the present extent of government ownership of railroads. For several years before the war the *Archiv für Eisenbahnwesen*, the official publication of the Prussian Ministry of Public Works, issued annually a compilation showing the mileage of railways in the various countries which was owned by the governments and by companies. In the year 1913, according to this authority, the total railway mileage of the globe was 690,133 miles. Of this, 464,421 miles, or 67 per cent, was owned by companies, while 225,712 miles, or 33 per cent, was owned by governments. Most—or to be specific, 256,823 miles—of the mileage owned by companies was in the United States. Even outside of America, however, the mileage owned by companies was 207,598 miles, or only about 18,000 miles less than the total mileage owned by governments.

It is often asserted in the United States that government ownership of railroads has become the policy of almost all the world except the United States. The foregoing statistics indicate that this is not the case, nor does a further analysis of the statistics of the world's railways lend support to this view. Before the war out of 75 countries which had railways, 40 had more mileage that was owned by companies than by the state, while 35 had more mileage that was owned by the state than by companies. In only seven of these countries were there no privately owned railways, while in 26 there were no government-owned railways. In some of the leading countries of the world private ownership preponderated while in other leading countries government ownership preponderated. In the United States and Great Britain all the railways were privately owned, and in France, Belgium, Spain, Sweden, Canada and Argentina private ownership preponderated. In Germany, Austria-Hungary, Russia, Italy, Mexico, British India, Japan and Australia government ownership preponderated.

Since 1914, when the war began in Europe,

there probably has been a greater increase in the mileage owned by governments than in that owned by companies. For example, in 1913 Canada had 27,687 miles of railway, of which only 1,781 miles was owned by the government. Some railways whose bonds the Canadian government had guaranteed, fell into financial difficulties, however, and the government took them over, with the result that of the now existing 40,000 miles in Canada about 13,500 miles are owned by the government. The extension of government operation has been even greater than the extension of government ownership. All the private railways of France, Great Britain and the United States were taken over by the governments during the war, and, therefore, during the war about five-sixths of all the railway mileage of the globe was state-operated. When, on their entrance into the World War, the governments of France, Great Britain and the United States took control of the railways it was freely predicted that in none of these countries would they ever be returned to private operation. This prediction probably will be shown to have been incorrect. The French seem disposed to return to private operation the railways owned by companies as soon as practicable. The experience of the French public with state operation of the Western Railway, which was taken over in 1908, has created sentiment against government management. The British Parliament has passed a bill providing for a continuance of government operation for two years. At one time nationalization of the British railways seemed inevitable, but after the signing of the armistice strong opposition to it sprang up. The experiment of government operation in the United States resulted in the development of an overwhelming sentiment against that policy, and President Wilson announced that the railroads would be returned to operation by the companies at the end of the year 1919.

Therefore, in spite of the extent to which government operation was adopted during the war, it appears probable that the war will not result in greatly changing the proportion of the railways of the world owned by governments, and that the question of government versus private ownership and management will continue to attract much public attention and be widely discussed for many years. Recently there was started in the United States a movement to have the government acquire the railroads, but, instead of managing them itself, turn them over to the management of a board of directors of 15 members, five to be appointed by the President of the United States, five by the railway officers and five by the railway employees. Under this plan any surplus over fixed charges earned by the railroads would be divided equally between the employees and the government, while any deficit incurred would be paid by the public. While much energy has been put into the propaganda for this plan, and it has been endorsed by most of the organizations of railroad employees, it has not met with much public favor. It seems probable that if the railroads of the United States are ever acquired by the public they will be managed by the government. One of the principal arguments which have been ad-

vanced in favor of government ownership in the United States as well as elsewhere is that an economy would be effected by reducing the return on capital which would have to be paid. The spokesmen of the railroad companies claim that they must be allowed to earn approximately 6 per cent upon the value of their properties in order to pay a return upon the existing investment and raise sufficient new capital to provide needed additional facilities. As a matter of fact, the return paid by the companies upon their outstanding capitalization never has exceeded $5\frac{1}{2}$ per cent in any year, but they have at times earned more, when most of their surplus earnings have been invested in the properties. It has been claimed that whereas the companies insist upon being allowed to earn 6 per cent the government would not have to pay more than $3\frac{1}{2}$ or 4 per cent upon its bonds. It is pointed out in reply, however, that in order to raise money to play its part in the Great War the government finally was obliged to pay interest at the rate of 4 $\frac{3}{4}$ per cent; that in order to acquire the railroads it would have to issue at least \$15,000,000,000 to \$20,000,000,000 in bonds, and that it could not market such a vast amount of bonds unless it paid 5 per cent or more interest on them. Therefore, it is contended, the saving in the capital charge under government ownership would be small.

Another argument which has been made for government ownership is that under that policy large economies would be effected by consolidating the railways, eliminating all competition, together with the officers and the employees kept on the pay rolls to carry on competitive activities, and operating the railways as a single system. Before government operation was adopted the operating economies which advocates of government ownership claimed could be made in the United States in these and other ways were estimated at from \$400,000,000 to \$1,000,000,000 a year. The opponents of government ownership claimed that the wastes of competition and the economies which could be effected by government management of the railroads as a single system were enormously exaggerated. They also claimed that while some economies undoubtedly could and would be effected under government operation, the destruction of individual initiative and enterprise, and the introduction of political influences, would result in increases of expenses which would much more than offset any economies that might be made. They contended that comparisons between the state managed and the privately managed railways of the world showed that the latter were usually more economically managed than the former. The actual experience of different countries with government management of railroads before the war yielded widely differing results. The evidence indicated that the state railways of Prussia, of Japan and of British India were quite efficiently operated. Comparisons between their operating results and those of the most efficiently operated private railways of the world, such as those of France, Canada and the United States, indicated that the most efficiently managed state railways probably were not quite as economically run as, and did not give any better service than, the most efficiently managed private railways; but when, as nearly

as was practicable, allowance was made for differences of condition, the impartial student was obliged to admit that the difference in efficiency indicated was not very great. An outstanding feature of the results of government operation was that all the state railways, the results of whose operation indicated an efficiency in management approaching the efficiency of management indicated by the results of the leading privately owned railways of the world, were owned and managed by autocratic governments. The opponents of government ownership in such countries as the United States and Great Britain pointed out that under the autocratic governments of Prussia, Japan and British India, the railroad employees were practically without political influence and were not even allowed to form labor organizations. They claimed that in countries having democratic governments, where railroad employees constitute a large part of the voters and where they are allowed to form powerful labor unions, government management almost invariably has been relatively inefficient and uneconomical. They made the inference that while state management may be successful when conducted by an autocratic government it cannot be made successful in a country having democratic institutions. They also cited statistics to show that in countries such as France and Canada, where there are both government managed and privately managed railways, the former are less economically operated than the latter, and that usually when railways have been transferred from private to government management, as in the cases of the Western Railway of France, the Northern Railway of Austria and the railways of Italy and Switzerland, there usually has followed a marked increase of operating expenses.

Probably the most striking example of an increase in railroad expenses following a transfer from private to government management is that which occurred in the United States during the World War. In 1918 the operating expenses of the railways of the United States were \$1,150,000,000, or 40 per cent more than they were under private operation in 1917. In the first six months of 1919, under continued government operation, they were 51 per cent greater than they were in the first six months of 1917, although much less business was handled. The defenders of government management claim that this great increase of expenses was not due to government operation but to advances in wages and increases in the prices of fuel and materials which were unavoidable. The defenders of private operation concede that most of the increase in expenses was not due to government operation, but call attention to the fact that the huge savings it was claimed would be made under that policy have not been effected, and claim that a very large part of the increase of expenses was due to government operation and would not have occurred under private operation. It has been urged that the increase in expenses was largely due to abnormal conditions created by the war. The advocates of private management, however, call attention to the fact that during the year following the signing of the armistice operating expenses continued to increase. Another argument which has been made in favor of government ownership is that under private

ownership the railroads make large profits which are received by private capitalists, while under government ownership the profits earned go into the public treasury, or, if no profits are earned, it is because relatively low passenger and freight rates are made under state management. In support of the contention that under government ownership the public may derive large profits from the railways the advocates of government ownership may cite the examples of Prussia and Japan. Before the war the state railways of Prussia usually earned from 5 to 8 per cent upon the investment and the earnings in excess of interest charges were used for public purposes. In the years 1910 to 1917 inclusive the state railways of Japan earned from 5 to 7 per cent upon the government's investment in them, which substantially exceeded the interest on the investment.

The opponents of government ownership point out, however, that in a large majority of the countries that have tried state management, and especially in those having democratic governments, state railways usually have incurred deficits. Deficits incurred by state railways must be paid by the taxpayers while railways which are owned by companies, always, whether profitable or not, must pay large amounts in taxes. Among the state railways which have incurred large deficits are those of Italy, France, Canada, most of the Australian colonies, Austria, Russia and so on. Even the railways of the German states except Prussia usually have incurred losses. During the first year of government operation in the United States (1918) a deficit of approximately \$250,000,000 was incurred, and in the first half of 1919 a deficit of approximately \$300,000,000 was incurred in spite of the fact that in June 1918 the government advanced freight rates 25 per cent and passenger rates 50 per cent. The losses incurred by most state railways cannot be fairly attributed to the lowness of their rates. In some cases they make relatively lower rates than private railways, as, for instance, has been the case on the Intercolonial Railway of Canada, but this railway usually has not even earned its operating expenses. In France the passenger and freight rates of the state railways have been about the same as those of the private railways, and before the World War the rates of the French private railways were slightly lower than those of the Prussian state railways. Generally speaking the tendency has been for private railways to make their freight rates lower than those of state railways, and for state railways to make their passenger rates lower than those of private railways. The opponents of government ownership contend, and apparently the facts favor their contention, that the deficits incurred by most state railways are not due to the lowness of their rates but to the relative lack of economy in their operation. One of the arguments against government ownership and management which have been pressed the hardest, and especially in the United States and other democratic countries, is that under that policy railroad management is thrown into politics, with the result of both undermining the efficiency of management and demoralizing politics. The advocates of government ownership claim, on the other hand, that under private ownership the railroad com-

panies are always a demoralizing influence in politics and that the only way to remove them from, and keep them out of, politics is to have the government acquire and operate them.

Evidence can be cited in support of both these contentions. For many years the railway companies of the United States hired lobbyists, kept politicians on their pay rolls, distributed free passes and used other means which gave them a great, and sometimes even dominant, influence in the politics of many States and even of the nation. But since effective regulation of railways was adopted in the United States, beginning about the year 1906, the companies have been deprived of the opportunity to exert any considerable influence in politics.

The railroads and politics have not had much, if any, effect upon each other under state ownership in countries with autocratic governments such as those of Prussia and Japan before the World War. On the other hand, the evidence demonstrates that "the railroads have corrupted politics and politics has corrupted the railroads" under the policy of state ownership in France, Canada, South Africa and numerous other countries. To keep the state railroads out of politics and politics out of the state railroad managements the governments of several countries, including those of the Australian colonies and of the Union of South Africa, have turned the management of the state railways over to railway commissioners who have been given by law a large amount of independent authority regarding railroad operation. In Canada the state railways recently have been turned over for operation to a company called the Canadian National Railways Company. While the government is practically the sole stockholder in this company, complete authority for the management of the railroads is given to the directors and officers of the company. It is generally agreed, however, by those who have studied state management in democratic countries, that there is a constant tendency for politics to break down all the barriers which are set up to prevent it from influencing railroad management, and for railroad employees to resort to political action for the promotion of their special interests.

The theoretical argument which may be made in favor of government ownership is very attractive and persuasive. The evidence indicates, however, that in all cases where state management of railroads has been measurably successful, it has been carried on under highly centralized and practically autocratic governments. In no democratic country has there been attained anything approaching the success in the state management of railroads which has been attained in Prussia and Japan. The real explanation of this seems to be that the management of railroads is chiefly a matter of administration. In governments such as Japan and Prussia had before the war, the administrative branch is strong and highly developed and dominates the legislative branch to such an extent that there is little chance for interference by the legislative branch with the management of the railroads. On the other hand, in democratic countries the legislative branch usually, under normal conditions, dominates the administrative branch, which results, where railways are owned by the state, in constant

interference by the legislative branch with railroad management. But the management of railroads is an undertaking to the efficient supervision of which a legislative body is badly adapted. It would appear from past experience that if democratic governments are to make a success of government ownership and management of railroads, they will have to follow the example set by autocratic governments before the war, in giving the railroad management almost complete freedom from control and interference by the law-making body. Whether this would be consistent with democratic principles, or, in fact, with the permanent maintenance of democratic institutions, may be questionable.

RAILWAYS, Street. This designation is inclusive of what is commonly known as *trolley* line development and includes not only city and suburban but interurban electric roads. Electric railways are by far the most important class of roads. Of the 986 companies included in this group, four use animal power, eight cable and two use gasoline motors as the motive power for a portion of the track. The electric railway companies operate about 99 per cent of the total trackage. Only nine companies in the United States use animal power exclusively, although this was practically the only kind of power used 35 years ago. The number of revenue passengers carried per mile of track indicates a steady increase in density of traffic from 212,259 in 1902 to 216,522 in 1907; 232,556 in 1912 and 251,684 at the present time (1919). The recent relatively large increase in cars, other than passenger cars, is due to the develop-

ment of freight business on interurban lines. Since 1890 electricity has practically superseded all other kinds of power.

The percentage of trackage operated by electric current increased from 15.5 per cent in 1890 to 99.6 per cent in 1919. Cable and steam power were never extensively used in the operation of street railways, but they reached their maximum about 1890.

The track operated by all street and electric railways includes not only the first, second and other main tracks, but also sidings, turnouts, track in car barns, storage yards, etc. The length of these various kinds of track, in single-track miles, amounted to 41,064 miles in 1912, as compared with 48,638 miles in 1919. Electricity is used on 40,601 miles of the foregoing 41,064 miles of street and electric railway track. All classes of non-electric power are continuously decreasing. The *overhead trolley* is rapidly decreasing although it was practically in universal use a few years ago, 38,958 miles being thus operated in 1912. The *third rail* system, being limited to elevated structures, subways, tunnels and tracks on private right of way, is still of minor importance. The conduit system, sometimes referred to as *conduit trolleys* is the most expensive type of electric traction construction and is in use only where municipal regulations prohibit the use of overhead trolleys. The greater proportion of street and electric railway track is on streets or public thoroughfares, but the suburban companies often own their rights of way or have obtained the privilege of operating tracks on private ways and in districts where interurban lines are extensively developed a large portion of the track is on private rights of way.

It is probable that more interest centres around the number of passengers carried than around any other feature of the railway service. While the increases in capital, miles of track, rolling stock, etc., show the development of the industry, no other fact is so impressive as the great number of people carried annually on the street and electric railways and the constant increase in passenger traffic. The total number of passengers in 1912 aggregated 12,135,341,716, as compared with 13,876,214,662 in 1918. The maximum density of passenger traffic centres in Manhattan and the Bronx boroughs of New York City.

No more startling changes in the street railway industry have been shown in years than

SUMMARY FOR STREET RAILWAYS OF ALL CLASSES IN 1918.

Showing operating companies, lessor companies, railways operated by electric power, cable roads exclusively, railways operated by gasoline motor power and railways operated by animal power.

	Total	Operating companies	Lessor electric companies	Operated trackage, classified by kind of power			
				Electricity (wholly or in part)	Power other than electric exclusively		
					Cable	Gasoline motor	Animal
Number of companies.....	1,276	983	293	986	9	6	7
Miles of line.....	31,105.35	26,234.18	4,971.17	31,021.56	13.84	58.64	11.31

Number of revenue passengers.....	10,164,514,304	10,164,514,304		8,445,951,141	14,187,331	964,214	213,416

those in its cars. In the effort to deal with problems of congestion, low rates of fare, public convenience in entering and leaving cars, the full collection of fares and safety in operation, an extraordinary number of new types have been evolved, each with its special merits. The past decade was particularly marked by an outburst of originality in this respect and probably no previous period in street railway history showed so many innovations. The modern stimulus in car design for city service may be said to have begun with the successful demonstration of the pay-as-you-enter car, which originated in Montreal and was shown first in the United States at the Columbus convention of the American Electric Railway Association in 1906. The later developments were in the extension of this principle to centre entrances, with an increase in accessibility to the car, in greater attention to safety features and in renewed use of one-man cars. Early in 1912 came first the New York *stepless* car with a body hanging near the ground between the trucks and then the low centre-entrance cars of Brooklyn and Washington and the centre-entrance, end-exit car of San Diego. These were accompanied by the *low-floor* car of Pittsburgh, in which 24-inch wheels and small motors eliminated one step and reduced the weight to an unprecedented figure. Double-deck cars based on these designs became almost obvious and came into use in 1913. In the meantime, the *near-side* principle, developed during 1911, had been applied to one-man cars, thus supplying a need for light-traffic service which had existed, but had been neglected, since the bobtail horse car disappeared. One of the most extraordinary developments was the *articulated* car of Boston, consisting of two old single-truck cars set end to end and flexibly connected by a low-hanging vestibule with centre side doors. Last among the radical designs came the storage battery *stepless* type, a four-wheeled car without a truck frame and of extremely light weight. The articulated car is primarily adapted to the rebuilding of old equipment and provides an answer to the question as to what disposition can be made of old rolling stock rendered obsolete by the introduction of new types. The new types of cars for interurban service and for heavy electric traction are less numerous and less divergent from previous types. The steel cars of the Cambridge Subway probably show a greater departure from generally accepted standards than any of the other large cars. They are equipped with three side doors and the usual platforms, bulkheads and platform doors are eliminated. In general the use of steel for car bodies has shown a marked increase. Most of the new types of city cars depend upon the girder effect of the side sheathing between belt rail and sills to support the load, the strains being carried around the doorway by heavy reinforcement. In 1913 the Chicago Elevated Railways brought out the all-steel arched-roof cars. This design was considered more economical from a maintenance standpoint as it was believed that this type of car would have a much longer life than those of composite construction. (See RAILWAYS, ELEVATED). Storage-battery cars have recently come into notable use again and various types have been adopted during the last few years in different cities and for various classes of

service. Batteries of the steel-nickel or lead-lead plates are employed and the cars themselves exhibit a great variety of style and feature.

Maintenance of track is one of the large and serious problems of the street railway industry. A few years ago there were no fewer than 200 different types of rail in use. The girder rail development had reduced the number to four standard types, the nine-inch grooved rails and T-rails being most satisfactory. A very large amount of T-rail construction is in use throughout the country and there is abundant evidence as to its persistence as a type. In any track construction in paved streets the pavement is perhaps the most important feature, in relation both to total cost of the track construction and to the use of the street by the public and practically all of the objection which has been raised to the T-rail construction should more properly have been brought against the type of pavement used in connection with that rail.

A very marked improvement has been seen in the illumination of street cars during the last decade. By reason of the universal use of electricity in car propulsion, the lighting has also become electrical in like degree, but it has had to pass through considerable change and evolution from carbon-filament, tantalum-filament and graphitized-carbon lamps up to the modern tungsten. Although the incandescent filament lamp has been used for the lighting of street railway cars practically ever since the electric motor cars superseded the horse or cable cars, it was not until very recently that any attempts were made to utilize the generated light to best advantage by means of scientifically manufactured shades or reflectors; and it was not until 1912 that the tungsten-filament lamp of an efficiency of 1.4 watts per horizontal candle or better was perfected to the extent of making it sufficiently rugged for street railway service. Lighting energy, being but a small fraction of the total energy used by motors and being relatively cheap to generate, has not been considered as a field for economy.

An increased amount of attention has been recently paid to the subjects of signaling and dispatching on electric railways, including the use of automatic stops, or such devices as the dictaphone; while even the telegraphone, with its fine running wire to receive magnetically the record of vocal orders, has been under serious consideration in large electric railway systems in cities for "load dispatching" purposes, where it is desirable to know just what instructions have been given from one power plant to another. The main thing, of course, is the control of train movement or the automatic stopping of trains otherwise out of control. The rapid and noteworthy development in block and light signaling led to the standardization of apparatus of the different methods of control for signals; the continuous track circuit has maintained its leading position among installations on high-speed lines. This may be due partly to conservatism in following a method so universally used by the steam railroads, although one of the advantages claimed for it, namely, that it indicates broken rails, can hardly be said to apply with much force to electric railways. It has, however, a similar advantage in that it indicates defective bonding by the

failure of the signals to clear. Various forms of the trolley-contact system have been installed on a number of railways. Their greatly reduced cost offers a strong incentive to installation. In addition, the possibility of introducing a car-counting device by giving the contactor a directional sense makes this system of unusual advantage where permissive signals, allowing cars to follow one another in the same block, are desired. Permissive blocking, however, except for very low speeds, is regarded with decreasing favor. The use of the telephone in train or car dispatching has become so general a thing as to excite no comment.

It is difficult to enumerate all the improvements which, step by step, have brought the electric railway motor up to its present condition of efficiency and durability. Its evolution began in the early eighties and is practically all confined to a period of about 35 years. The enclosed type of motor resulted from the large amount of trouble experienced from mud and water splashing into the early types and causing their insulation to break down. The use of the four radial poles followed the attempt to get the most compact as well as the lightest design for street-car motors. Laminated pole pieces were introduced to decrease the loss from eddy currents in the pole faces which, with the high inductions introduced with the slotted armature and small air gaps, increased greatly the total loss in the motor. Later the generator practice of saturating the pole tips by cutting off alternate pole tips from the punchings was introduced. The use of mummified strapwound field coils with asbestos insulation has become practically universal and the use of round wire is permitted only on the smallest sizes of motors, where no gain is secured by the use of the flat copper ribbon. No improvement has been marked or has done more to keep the motor cars out of the repair shop than the introduction of the standard type of bearing housing and method of lubrication. The life of the bearing on the motor may now be quite up to 400,000 miles. The modern armatures and brush holders are great improvements over the earlier forms not only in accuracy of adjustment but in simplicity of insulation, substantialness of design and the use of adjustable frictionless springs. Undoubtedly the most positive power saver which has been introduced with the interpole motors is field control. This, as is well-known, is simply a revival of the old control system, used in some of the earliest railway motors. The early double-reduction motor made the most extensive use of this, since the control was entirely by commutating the field and employed no external resistance at all.

The subject of fares is one of vital importance to every street and electric railway, as upon the income derived from transportation depend, the welfare and prosperity of the line, the ability to give good service, the proper upkeep of the system in all its physical details, the payment of wages acceptable to the employees, the increase of facilities for the public and the introduction of improvements. In practically all instances the fares now in existence are fixed by franchise, by agreement with the municipality or by valuation of the property, but the elements and bases, in fact the very principles referred to in determining rates and fares, re-

main a subject of constant discussion and experiment. The question of free transportation is governed quite largely either by franchises or by State laws and these have recognized to a large extent local conditions in cities and in States.

Modern street car development includes that of the elevated railways, restricted in this country to a few of the largest cities, such as New York, Philadelphia, Chicago, Boston and Kansas City, in most of which they have become an integral part of the surface street car systems, operating under the same management and providing for exchange of traffic. The use of steam on the elevated roads continued for many years without complaint and the service rendered was remarkable for its efficiency, safety and regularity. Because of a rapid increasing travel, necessitating more frequent trains, and because of the inability of steam locomotives of the necessary size to haul heavier trains at higher speeds over the structures, as early as 1885 a plan was formed for equipping sections of the elevated railways in New York City with electricity. In considering the design of a steel rail to act as a conductor and at the same time to give a good contact surface for the collection of current by a moving train several important features must be considered. Third-rail installations are generally divided into three classifications as to their point of contact with the collecting device, namely, over-running contact, under-running contact and side contact. The earliest installations were over-running or top contact in which the collecting device passed over and made contact with the open top of the third-rail. The first installation used a form of collector which depended on its own weight for contact with the third-rail and the installation was exceedingly simple. These first installations were on elevated systems where there was little or no danger of the public coming in contact with the rail. Later, when the use of the third-rail contact system was taken up by interurban roads and for steam road electrification where there were possibilities of accident to the public from coming in contact with a bare conductor, it became necessary to devise some better means for protecting the rail. This led to several types of protected third-rail, and later to the under-running and side-contact construction. See *AMERICAN STREET RAILWAYS* and *RAILWAYS, ELEVATED*.

RAILWAYS OF THE UNITED STATES. The aggregate length of the railways of the United States on 31 Dec. 1917 was approximately 265,000 miles, or about 50,000 miles more than the total mileage of European railways and about two-fifths of the total in the entire world. Excluding switching and terminal railways and a few minor lines performing strictly local services, as distinguished from interstate services, the total length of line, at the close of 1917, was 254,734 miles.

The development of the American railway system during successive decades is suggested by the following:

YEAR	Miles of line	Increase in miles	Increase per cent	Miles per 100 square miles of area	Population per mile of railway
1830.....	40				321,517
1840.....	2,755	2,715	6,788	0.13	6,194
1850.....	8,571	5,816	211	.29	2,706
1860.....	28,920	20,348	237	.97	1,087
1870.....	49,168	20,249	70	1.66	784
1880.....	87,724	38,556	78	2.95	572
1890.....	159,272	71,548	82	5.51	384
1900.....	192,941	33,669	21	6.51	393
1910.....	240,438	47,497	25	8.08	382
1917.....	254,734	14,296	6	8.57	412

The unequal distribution of American railway mileage, with respect to population and area, is indicated by the following table:

STATE	Miles of line 30, June 1916	Miles per 100 square miles of area, 30, June 1916	Population per mile of line, 31, Dec. 1917
Alabama.....	5,495	10.72	427
Arizona.....	2,410	2.12	108
Arkansas.....	5,294	10.08	331
California.....	8,441	5.42	354

Prior to 1890, the increase in railway mileage was much more rapid than the growth in population but since that year the railway construction has lagged until a comparison between 1890 and 1917 shows an increase of 28, or 7.29 per cent, in the average number of inhabitants served by each mile of railway. It may or may

not be considered significant that Federal regulation of interstate rates, as embodied in the Interstate Commerce Law, began on 4 April 1887, or at about the same time as the retardation of railway building. From 1877 to 1887, the mileage added to the American railway system was 110,164, or an average of 5,508 miles per year; from 1907 to 1917, the added mileage was 76,156, or at the rate of 3,808 miles per year. Unless it is conceived that the whole area of the United States is adequately supplied with railway facilities it must be concluded that in some way the relative incentive to the investment of capital in the railway industry has been diminished.

It is interesting, in its implications as to future development, to note that if the 11 States, California, Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Oklahoma, Texas and Wisconsin, contained railway facilities as liberally proportioned to their area as those of the Commonwealth of Massachusetts, their combined mileage would substantially equal the present mileage of the whole United States. This is shown by the following table:

STATE	Railway mileage in 1916	To establish relation to area equalling Massachusetts		
		Total miles	New construction	Per cent of new construction to present mileage
California.....	8,441	41,333	32,892	389.67

Considering the relative scarcity of capital, the rapidity with which new mileage was added from 1835 to almost the end of the 19th century is remarkable. Baltimore and Philadelphia were connected by railway in 1837 and Boston and Albany in 1842. During 1842, also, the last link in the chain of short lines connecting Albany and Buffalo was completed and the Baltimore and Ohio was extended to Cumberland. In 1851 the Hudson River Railroad, following the eastern bank of the Hudson from New York to Albany, and the New York and Lake Erie, connecting the west bank of the Hudson, opposite New York City, with Lake Erie, were placed in operation. The Baltimore and Ohio was extended to the Ohio River, at Wheeling, in 1853, and the Pennsylvania Railroad to Pittsburgh in 1854. Buffalo and Toledo were connected by rail in 1853 and the year previous witnessed the completion of the third line between Ohio and Lake Erie, the first having been finished in 1848. Chicago was reached by rail in 1852 and the Chicago and Rock Island was extended to the Mississippi River in 1854. Two years subsequently, a second and a third line from Chicago westward to the

MILES OF RAILROADS, BY STATES, JANUARY 1, 1918

Mississippi were added and the Illinois Central was built to the junction of the Ohio and Mississippi. The Hannibal and Saint Joseph, now a part of the Burlington system of railways, was the first line to reach the Missouri River, in 1859; in 1866 the Galena and Chicago was built to Council Bluffs, opposite Buffalo, and on 10 May 1869 the opening of the Central Pacific, with the Union Pacific and the railways already indicated, made it possible to travel by rail the whole distance from the Atlantic to the Pacific. Thus the outline of the American railway system was broadly sketched, the whole process being comprised within the years 1831 to 1866, or just half the "three score years and ten," supposed to constitute the allotment of a normal lifetime. Subsequent construction has filled in this outline, adding numerous railway routes which parallel those first laid down and supplying old and new railways with "feeders," extending their services to all important sources of supplies of raw materials and manufactured products and to all considerable centres of population.

At present six great systems, not including Canadian lines which compete with them even for a substantial volume of traffic having both its origin and destination in the United States, connect the north Atlantic seaboard with Lake Erie, four of them reaching onward to Chicago and three of these operating to the eastern bank of the Mississippi over their own rails. In a railway sense, New England remains an independent province, but its railways connect with the trunk lines and serve as collecting and distributing systems for interchanged traffic. Two railways, terminating upon Chesapeake Bay, at Norfolk and at New-

independent line now in alliance with one of the northern transcontinental systems. One of these "granger" railways has been extended to Puget Sound and four have built or acquired lines into Kansas City. Seven lines connect the Gulf of Mexico with Saint Louis or Chicago, while seven "transcontinental" systems link the Pacific Coast with the Mississippi Valley. Seven railways serve the anthracite region of Pennsylvania and, in the East, five are especially characterized by heavy traffic in bituminous coal. Within this system certain railways have been developed along narrower lines and performing functions still more closely specialized, like the Virginian Railway, which is distinctively a carrier of soft coal; the Florida East Coast Railway, which handles the winter resort traffic of Florida; the Pere Marquette Railway, which is largely occupied in the service of the special agricultural production of the lower peninsula of Michigan, and the Bessemer and Lake Erie Railroad, which holds distinctive relations with the traffic in ore and coal between the Great Lakes and the Pittsburgh district. In addition there are many systems of minor extent which have industrial relations of less general significance but having relatively no smaller share in the economic existence of the nation.

There have been great changes in the geographical distribution of railway mileage. In 1860 the whole region west of the Great Lakes and Mississippi River contained but 2,745 miles of line or 9 per cent of the country's mileage; in 1917 this region contained 128,733 miles or nearly 52 per cent of the total. The following table shows the changes in distribution in greater detail:

GROUP	Miles				Miles per 1,000 miles in whole country			
	1860	1880	1900	1917	1860	1880	1900	1917
Connecticut, Delaware, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, Vermont, District of Columbia	10,013	21,129	29,983	32,095	327	227	155	129

Total	30,626	93,267	193,346	249,947	1,000	1,000	1,000	1,000

port News, compete for traffic between the north Atlantic seaboard and the Mississippi Valley, their services being supplemented by those of coastwise steamships with which they have traffic arrangements enabling the acceptance of freight at through rates named for the combined water and rail service. Three systems connect the eastern cotton States with the Potomac River or the Chesapeake. The spring wheat States and those of the corn belt, west and northwest of Chicago, are served by six independent systems, and by a formerly

The relations of this railway skeleton to the economic resources of the country and their organization are apparent. The north Atlantic ports are the centres of export and import trade and, with the adjacent territory, are fields of great manufacturing activity. The lines which radiate from these ports distribute manufactured and imported goods and bring to them raw materials and products for export. Chicago and the Mississippi and Missouri river cities are gathering centres for the food products of an area which now comprises nearly all of the

valley of the Mississippi and Missouri and stretches from the Canadian boundary to the Gulf of Mexico. Forest products formerly moved from the West eastward but are now brought mainly from the South or the Southwest or from the Pacific Coast. The distinctive products of the Pacific Coast and trade to and from the Orient and Alaska seek the transcontinental lines in order to gain access to the centres of population in the East or Middle West.

The important place of the railways as a part of the economic organism of the United States may be statistically indicated. The following table compares the number of employees with the total population, showing the steady increase in the proportion of the available labor of the country engaged in railway transportation:

YEAR	Population	Railway employees	
		Number	Per 10,000 of population
1880.....	50,155,783	418,957	84
1890.....	62,947,714	749,301	119
1900.....	76,085,794	1,017,653	134
1910.....	92,174,515	*1,699,420	184
1917.....	103,500,473	†1,780,235	172

* Not including employees of switching and terminal companies.

† For 458 companies operating 252,029 miles of line.

The foregoing data make no allowance for the large numbers employed in industries, such as locomotive and car-building and coal production, which serve the railway industry.

All measures of national wealth are subject to wide margins of error and in a smaller degree the same is true of the effort to assign money values to the properties that constitute railway capital, but the following comparisons at least indicate approximate relations at successive periods:

YEAR	National wealth	Railway capital	
		Amount	Per cent of national wealth
1890.....	\$65,037,091,000	\$8,040,707,804	12.36
1900.....	88,517,307,000	9,035,732,000	10.21
1904.....	107,104,211,917	11,244,752,000	10.50
1912.....	187,739,071,090	16,148,532,502	8.60

Since 1893 there has been a heavy marking-up of certain elements of national wealth, particularly real estate. For example, between 1900 and 1910 the reported value of farm lands increased from \$13,058,007,995 to \$28,475,674,169, or 118.1 per cent, although the total area in

farms increased less than 5 per cent, from 838,591,774 acres to 878,798,325 acres. The average value per acre indicated by these figures for 1900 is \$15.57 and for 1910 \$32.40, an increase of 108.1 per cent. There was no marking up of railway assets. The marking up of farm lands was made possible by the fact, among others, that while in 1900 there were 14.72 miles of excellent and highly efficient railway per 100 square miles of farm lands there were in 1910 17.51 miles of better and more efficient railway for each equal farm area.

The utilization of railway service has increased much more rapidly than population. The following table compares the total transportation of passengers, measured in passenger miles, with the population at successive periods.

YEAR	Population	Passengers carried one mile	
		Number	Per capita of population
1880.....	50,155,783	5,740,112,502	114
1890.....	62,947,714	11,847,785,617	188
1900.....	76,085,794	16,039,007,217	211
1910.....	92,174,515	32,338,496,329	351
1917.....	103,500,473	39,739,682,000	384

Although, as appears from the foregoing, the increase in railway passenger travel has been more than three times as rapid as that in population, the railway movement of freight has increased even more rapidly. This will appear from the following:

YEAR	Population	Tons of freight carried one mile	
		Number	Per capita of population
1880.....	50,155,783	32,348,846,693	645
1890.....	62,947,714	76,207,047,298	1,211
1900.....	76,085,794	141,599,157,270	1,861
1910.....	92,174,515	235,016,910,451	2,767
1917.....	103,500,473	394,040,446,000	3,807

Thus in 37 years during which population doubled, the movement of railway freight increased 12-fold; in the last 17 years, while population increased 36.03 per cent, freight movement increased 178.28 per cent.

This augmented service has been performed at rates that, measured in purchasing power over railway labor and railway supplies, have rapidly decreased and that did not fail to decrease steadily, even when measured in money, until the recent rapid decrease in the value of the circulating medium rendered some adjustment unavoidable. The following table shows the facts:

YEAR	Passenger service			Freight service			
	Passenger miles, per capita	Average rate per passenger mile, in cents	Average payment per capita	Ton-miles per capita	Average rate per ton-mile in cents	Average payment per capita	Total payment per capita
1880.....	114	2.442	\$2.78	645	1.232	\$7.95	\$10.73
1890.....	188	2.167	4.07	1,211	.941	11.40	15.47
1900.....	211	2.003	4.23	1,861	.729	13.57	17.80
1910.....	351	1.928	6.77	2,767	.763	21.11	27.88
1917.....	384	2.103	8.08	3,807	.728	27.71	35.79

RAILROADS

Copyright, Underwood & Underwood, New York

A completed modern 1200 volt electric locomotive for the South Manchurian Railroad. The Manchurian road is electrified for a considerable distance. This locomotive is used mainly for yard work and transporting coal in mining districts

RAILROADS

Copyright International & General, New York

1 A modern 3000 volt locomotive built for the Chicago, Milwaukee and Saint Paul Railway, which has 600 miles of electrified track in the Rocky Mountains

2 A modern 2400 volt locomotive for Chile, to be used on the railroad of the Bethlehem Chile Iron Mines Company. This is a very large locomotive — the same general type as used on the 400 miles of electrified road of the Chicago, Milwaukee and Saint Paul in the Rockies

Analysis of the foregoing shows that the average American paid about three and one-third times (333.55 per cent) as much for railway service in 1917 as in 1880 but obtained, in 1917, about six times (590.23 per cent) as much freight service and about three and one-third times (336.84 per cent) as much passenger service. Since 1900 the total payment, in money, has about kept pace with the increase in travel and traffic movement, but the value of the monetary unit has so decreased that railway service is almost the only commodity which has not increased in price. The wages of a day's labor in any industry and the product of a day's labor or of a dollar of capital or of an acre of land in almost any industry would buy vastly more railway service in 1917 than in 1900. For example, the following values of American wheat, stated by the Secretary of Agriculture, are compared with railway rates:

	1900	1917	Increase per cent
Wheat —			
Average farm price, per bushel.....	\$0.619	\$2.009	224.56
Average value of yield, per acre....	7.61	28.46	273.98
Railway Services —			
Average rate per passenger mile....	.02003	.02103	4.99
Average rate per ton-mile.....	.00729	.00728	Decrease
Wheat and Railway Service —			
Passenger miles per bushel of wheat...	30.90	95.53	209.16
Passenger miles per acre of wheat....	379.93	1,353.30	256.20
Ton miles per bushel of wheat.....	84.91	275.96	225.00
Ton miles per acre of wheat.....	1,043.90	3,909.34	274.49

The foregoing are not exceptional, they are typical; there is no commodity of commercial importance which will not show substantially similar results.

The results illustrated above have been rendered possible only by the enormous improvements in the science and art of railway transportation which the managers of American railways have achieved. Nowhere else in the world have comparable results been accomplished. American railway men have been pioneers in fields exclusively their own and have so far succeeded that the American railway system was able, at the end of 1917, to handle far greater tonnage with relatively lower expenditure of power, including labor and fuel, at a lower capital cost per unit of traffic, and to carry both passengers and freight at the lowest rates in the world while paying the highest rates of wages anywhere received by men similarly qualified. The summary of this evolution is in the average train load of freight carried during successive years for there are few exceptions to the rule that every improvement possessing genuine economic value ultimately resolves itself into higher train capacity. The data of the following table are, therefore, of the utmost significance.

The last increase, from 1915 to 1917, must astonish anyone not fully conversant with the railway conditions of 1917. The last contribution of private railway management to American efficiency in war was an increase in transportation of commodities per average train-mile of 145.55 tons in two years, or more than 50 per cent greater increase than that of any previous period of five years, with a per-

AVERAGE FREIGHT-TRAIN LOAD.

YEAR	Tons	Increase, five-years period	
		Tons	Per cent
1890.....	177.42		
1895.....	189.69	12.27	6.92
1900.....	270.86	81.17	42.79
1905.....	322.26	51.40	18.98
1910.....	380.38	58.12	18.04
1915.....	474.45	94.07	24.73
1916.....	534.95	*60.50	*12.75
1917.....	620.00	†145.55	†30.68

* One year, only.

† Two years, only.

centage increase for the two years greater than the percentage increase of any five years' period since the year 1900. Of this increase of 145.55 tons, no less than 85.05 tons increase, or 58.43 per cent of the total, was obtained during 1917.

The more salient features of the evolution by which such results have been attained are the addition of multiple tracks, including yard and terminal tracks, in order to secure more rapid handling of trains and cars and cargoes; strengthening of road-beds, bridges and other structures to enable the use of heavier locomotives having increased tractive power; increasing the power of locomotives and the capacity of cars in order to concentrate greater tonnage in fewer trains, requiring less power and smaller track and terminal space; reducing grades and lengthening the radii of curves in order to augment the efficiency of locomotives of given tractive power.

Some of these improvements are susceptible of statistical admeasurement. The proportionate mileage of additional tracks is shown below:

Additional tracks per 100 miles of line, in miles —				
	1894	1904	1914	1917
Second track.....	5.87	7.46	10.76	11.96
Third track.....	.53	.69	1.05	1.11
Fourth track.....	.40	.49	.81	.89
Yard track and sidings..	23.88	31.34	38.32	41.72
Total, all extra tracks.....	30.68	39.98	50.94	55.68

Increase in the power of locomotives began with the increase in the boiler pressure from 185 pounds to 220 pounds. With this accomplished, progress theretofore considered impracticable became a matter of developments in design and augmented size. The following shows what has been accomplished since 1902:

YEAR	Number of loco- motives	Average weight in tons	Average Tractive power, in pounds	
			Average	Total
1902.....	41,225	56.3	20,354	839,073,779
1907.....	55,368	69.1	25,811	1,429,636,658
1912.....	*61,010	77.0	28,634	1,746,964,128
1917.....	63,828	89.5	33,617	2,145,698,000

* Excludes locomotives owned by switching and terminal companies, 534 Mallet locomotives and 718 unclassified locomotives.

Derived from the foregoing, the following percentages establish rates of development which show no slackening during the period of private management.

	Increase, per cent			
	1902 to 1907	1907 to 1912	1912 to 1917	1902 to 1917
Number of locomotives..	34.36	10.15	4.62	54.83
Average weight.....	22.74	11.43	16.23	58.97
Average tractive power..	26.81	10.94	17.40	65.16
Total tractive power...	70.38	22.20	22.82	155.72

During the same period the number and capacity of freight cars have increased as follows:

YEAR	Number of cars	Capacity, in tons	
		Average	Total
1902.....	1,546,101	28	43,416,029
1907.....	1,991,557	34	67,216,144
1912 ^a	2,215,549	37	82,976,893
1917.....	2,384,765	40	94,590,333

^a Does not include cars owned by switching and terminal companies.

The foregoing shows an increase, for the 15 years' period, of 117.87 per cent in total freight car capacity, achieved by an increase of 54.24 per cent in the number of cars and an increase in average capacity per car of 42.86 per cent. The great value in the large car lies in the smaller proportion of the weight of the car to the paying load and the reduced effort required to move a load concentrated upon a relatively short aggregate wheelbase due to lessening of frictional resistance and air pressure.

Improvements in track and structures, signaling apparatus and methods of operation have kept pace with the more easily measured development of motive power and cars. Freight as well as passenger cars are now equipped with automatic couplers and air brakes. Safety appliances have been developed and standardized as to type and position.

The aggregate amount of work performed per mile of line has increased with the development described and suggested, with the following results:

YEAR	Per mile of railway line	
	Passengers carried one mile	Tons freight carried one mile
1880.....	65,434	368,757
1890.....	72,421	465,822
1900.....	82,935	732,362
1910.....	134,498	1,060,635
1917.....	157,678	1,563,472

The operating and financial results obtained may be further summarized as follows:

YEAR	Per \$100 of capital	Per \$1 available for return upon investment	
	Passengers carried one mile	Tons carried one mile	Passengers carried one mile
1890.....	156	1,006	36
1900.....	168	1,483	34
1910.....	226	1,779	39
1917.....	236	2,342	41

The period of inflation that accompanied and followed the Civil War had its natural reaction in the financial panic of 1873 and the years of business depression that ensued. The difficulties of this period produced the customary crop of politico-economic fallacies, including "Greenbackism," the precursor of the free-silver movement of 1896 and "Grangerism." The latter, in its inception an agrarian movement, assumed many phases most of them ephemeral, but left its permanent impress upon American legislation in the form of laws controlling railway charges and services. As the proponents of these laws proclaimed them as curatives for nearly all social and economic discomforts, they inevitably proved disappointing and were successively amended until by the

end of 1917 it was generally true that prompt adjustments of rates to such sudden and urgent conditions as those arising from the rapid rise in the cost of the labor, materials and supplies required in railway operation had become impossible.

Private management of American railways was temporarily suspended at the end of 1917 by a proclamation of President Wilson, exercising an emergency power conferred to provide for the great exigencies of war, issued on 26 Dec. 1917. By this exercise of supreme authority all the railway properties, save a very few of the least importance, were taken into the possession of the Federal government which now operates them through a director-general whose legal status is that of a direct representative of the President and whose responsibility is only to and through the President. The conditions which sanctioned this temporary expropriation are much misunderstood although they are not difficult of discovery or comprehension. By the end of 1917 every American industry had experienced enormous advances in its operating expenses by reason of advances in wages and in the prices of articles required as raw materials or for use in operation. All industries except the railways, and a few others subjected to similar public regulation, had made compensatory advances in prices and were enjoying an unprecedented degree of prosperity. The wages of railway labor and the prices of railway supplies had advanced with everything else but control of railway rates had been vested in the Interstate Commerce Commission and in the several State railroad commissions and without their express consent the necessary rate adjustments could not be made. The processes of these bodies were slow and their temper reluctant. While the railways waited for relief through official action the threat of financial disaster impended with increasing imminence, their credit faltered and it became evident that the fiscal condition of the railways might become an impediment to the financing of the war. The President recognized the situation, and having emergency power to take possession of the railways, as a war measure, although he had none to expedite or control the various commissions whose methods made the more radical step expedient, exercised his authority by taking the properties from their owners and vesting their management in a Federal officer, responsible only to himself. By this means he was able to provide for an almost immediate adjustment of rates of fare and freight, by increases regarded as adequate to compensate for increases in necessary costs of operation, and in the meantime to provide that the deficits should be borne out of the public funds. It cannot be too often or too strongly stated that the financial conditions resulting from public regulation were the sole cause and must forever constitute the sole justification for this step. The railways had never functioned as efficiently as throughout the 12 months which ended with 31 Dec. 1917; they did not, all things considered, function with in any degree superior efficiency during 1918.

By an Act of Congress, approved by the President on 21 March 1918, the conditions of this Federal possession were fixed and its duration limited to the duration of the war with the Central Powers and 21 months thereafter,

subject to the discretionary power of the President to relinquish possession at an earlier date. The constitutional right of the owners of the properties to "just compensation" was protected, in the same act, by a grant of jurisdiction to the Court of Claims to entertain and determine suits to fix damages for such taking and use of corporate property, but provision was also made for contracts guaranteeing remuneration equivalent to the average earnings of the three years' period that ended with 30 June 1917. By the end of the first quarter of 1919, such contracts had been negotiated between the Federal authorities and a considerable number of the more important railway corporations, but there were still many which had not accepted the terms offered or as to which negotiations had not been pressed to completion.

The sudden transformation from private management, subject to public regulation, to public management, thus effected has produced an entirely novel series of problems the character and dimensions of which are only beginning to become capable of recognition. They involve fundamental questions of public policy, of political and economic institutions and will require decisions which must be made within a brief period, that are certain to affect the moral and material welfare of the people for many generations. The American people have not been committed to and certainly do not desire government ownership or operation of their railway system. In proclaiming the assumption of possession by the Federal government, the President declared his purpose to preserve the operating organizations and their personnel and to do nothing to impair the rights of ownership. Congress supplemented this by an explicit legislative disclaimer of any purpose even to lay a foundation for a permanent change of ownership or of immediate control. Moreover, as the experiment continues it becomes increasingly evident that it offers nothing of attraction adequate to replace the advantages experienced during the long period of progress under regulated private management.

RAIMONDI, rî-môn'dê, Marc Antonio (MARCANTONIO), Italian copper-plate engraver: b. Bologna, about 1480; d. there, about 1534. He acquired the goldsmith's art in France and

was especially successful in niello, but finally gave all his attention to engraving on copper. In 1505 he went to Venice and attracted attention by his copy on metal plate of Dürer's 'Life of the Virgin.' He was later attracted to Rome, where Raphael soon selected him as the engraver of his pictures. After Raphael's death Giulio Romano commissioned him to make plates from 20 of his best paintings, but having reproduced some licentious designs of that artist, Pope Clement VII ordered the plates to be destroyed by the public executioner and Raimondi was cast into prison. He was released through the intercession of the sculptor Bandinelli, and to show his gratitude Raimondi made a copy in line engraving of Bandinelli's 'Martyrdom of Saint Lawrence.' Losing his property in the sack of Rome (1527) he returned to Bologna, where he died a few years later. The value of his engravings after Raphael lies in the fact that they were executed under that artist's eye, and were many of them copies, not of completed pictures, but of rough draughts and tentative designs, which but for these copper-plate reproductions would have been lost to the world. Being thus brought in intimate relation with the painter's methods, he became the best interpreter of Raphael in black and white, and no engraver has so completely entered into the spirit and power of expression which breathe in the canvas of the greatest Italian painter. His best engravings after Raphael include 'Adam and Eve'; 'God Commands Noah to Build the Ark'; 'The Massacre of the Innocents'; 'Mary with the Dead Christ'; 'The Judgment of Paris'; 'The Three Doctors of the Church.' Consult Delaborde, 'Marc-Antoine Raimondi' (1887).

RAIMUND DE SABUNDE, rî'moond də sā-boon'dă, scholastic philosopher: b. Barcelona. In 1436 he appears at Toulouse as a teacher of medicine, philosophy and theology, and he labored especially to reconcile the apparent contradictions between nature or reason and the Bible, an undertaking which led him into the realm of mysticism. In his 'Liber Creaturarum seu Theologiæ Naturalis' he applied this principle so as practically to reconstruct the whole system of Church doctrine. He and his system have been discussed by Matzke (1846), Huttler (1851) and F. Nitzsch in the 'Zeitschrift für historische Theologie' (1859).

RAIN (Lat. *rigare*; Gk. *βρέχειν*, to wet), water dropping through the atmosphere. A mass of air in the atmosphere always contains some aqueous vapor, and if this air is cooled below a certain temperature, called the dew-point (which depends on the amount of vapor present), the vapor will condense into drops of water. The cooling may be due to radiation of heat to colder regions or to mixture with colder masses of air. When air rises in the atmosphere to colder regions, or comes in contact with a cold part of the earth, or passes from equatorial to polar parts of the earth, its moisture tends to condense into rain. In considering the probable rainfall of a place we are concerned with its latitude, its elevation above the sea, its proximity to the sea, the laws affecting its seasonable variations, the prevailing winds and the configuration of the surrounding surface. Low latitudes have in general a heavy rainfall, because of the greater evaporation in

tropical regions, and the consequent formation of rain when the clouds due to evaporation get colder in the higher regions of the atmosphere. Hence also winds blowing from the equator are generally moist and winds blowing to the equator are generally dry. The presence of forests tends to increase the rainfall (see METEOROLOGY), and the rain further encourages vegetation. Over the ocean the skies are clear where the trade-winds are blowing steadily, and heavy rain falls by day in the zone of calms; on land there is a regular alternation of dry and wet seasons. Toward the equator, where there is a considerable interval between the two passages of the sun across the zenith, there are two rainy seasons. In monsoon regions, however, the alternation of dry and wet seasons depends on the winds. Beyond the tropics we have variable winds and variable rainfall. The following table gives recent figures for the mean annual rainfall of a number of stations in various parts of the world:

	Inches		Inches
Greytown (Nicaragua)	260	Perth (Australia)	32
Freetown (Sierra Leone)	125.8	Saint John (New Brunswick)	31.75
Rangoon	99	Ottawa	31.4

It has been proven that rain has a most cleansing effect on the atmosphere, a five days' rainfall in London, England, having carried off not less than 3,738 tons of solid impurities, including 267 tons of sulphate of ammonia, and 2,000 tons of soot and suspended matters.

Rain water would be a chemically pure water but for the variety of impurities which it collects from the atmosphere in its descent. These include dust, soot, fungi spores, pollen, etc. Rain water also carries a small amount of nitrogen, ammonia, oxygen and carbonic acid gas, and in certain areas, usually over large cities, there are also present minute quantities of nitric acid and sulphuric acid. Rain water thus carries several of the necessities of plant and

animal life to the earth's surface. It becomes safely potable for man only after filtration through the earth's strata, whence it emerges in springs, artesian wells, etc. Until about 1850 scientists supposed rain to be due to the mixture of cold and warm bodies of moisture-laden air. Espy first propounded the theory that it was due to the cooling of the atmosphere under the expansion of the more heated portions of air. Lord Kelvin and others soon proved this theory correct. When air expands on the withdrawal of pressure the work done in expansion is evidenced by a lowered temperature of the expanding air. By convection the warm moisture-laden air ascends and in the course of its ascent is gradually cooled until it reaches the point at which its temperature is the dew-point of the original air. Cloud is then formed and if the moisture is abundant the smaller particles coalesce into drops and fall rapidly as rain. If they do not coalesce they may continue to reach higher areas until they become ice particles. The seasonal distribution of rainfall is of greater moment to the agriculturist and stock-raiser than the total annual amount. The ideal, seldom attained, would be an equable division of temperature, rain and sunshine throughout the year. For details of the distribution of rainfall throughout continental United States consult Henry, A. J., 'Rainfall in the United States' (in 'Weather Bureau Bulletin D,' Washington, D. C., 1879); 'Rainfall and Charts of Rainfall' (in *Monthly Weather Review*, ib., April 1902); and Wallis, B. C. (in *Monthly Weather Review*, ib., January, April, June issues 1915).

RAIN-BIRDS, various birds so called because of their observed or supposed connection with rains or the foretelling of wet weather. The cuckoos seem to be most widely credited with foreknowledge of storms, as they are in the habit of calling most noisily at such times. Thus the yellow-billed cuckoo (see Cuckoo) is called "rain-crow" in the Southern and Western States. Further southwest and in Mexico and Central America the name is given to the anis; while in the West Indies two or three other cuckoos are so termed. These are familiar species of the genera *Saurorhina*, *Heterornis* and *Piaya*, the last named extending over most of the Andean region. The rain-bird of India is a quail (*Coturnix Coromandelica*), which recalls one of the names, "wet-my-hip" of the American eastern quail; and that of the Malay region is one of the broadbills (*Cymborynchus*). In England the green woodpecker is called "rain-bird"; and in the Orkney Islands one, the loons, especially the red-necked, is known as "rain-goose." The prophetic power of the birds is exaggerated in popular estimation; but probably they do somewhat perceive a coming change of weather, especially of increased moisture, and those, like the above mentioned, which are naturally noisy, do then call more loudly and frequently than usual.

RAIN-GAUGE, or **PLUVIOMETER**, an instrument which measures the depth of the rainfall. In its commonest form it consists of a cylindric vessel closed at the top by a funnel-shaped lid, through a hole in the centre of which the rain falls. A narrow glass tube, rising outside the vessel from near the bottom,

shows by the height of the water in it the height of the water in the vessel itself. A very simple rain-gauge consists of a copper funnel, the area of whose opening is exactly 10 square inches. This funnel allows the rain to pass into a bottle, and the quantity of rain caught is ascertained by multiplying the weight in ounces by 0.173, which gives the depth in inches. The Weather Bureau at Washington has perfected several forms of rain-gauge for more accurate observation. One of these weighs the water as it accumulates in the receiver and records regularly the gain in weight on a moving strip of paper. In regions where the rainfall is very slight there is a demand for gauges that will record the entire fall for a month or three months, and such have been made to meet these special demands. As a rain-gauge is nearer the ground it is found to indicate a greater rainfall. This is partly due to the cold rain-drops getting larger in falling through the very moist air near the ground and partly to the greater occurrence of eddies about the gauge at greater heights. Hence, when the rainfall at two places is to be compared, the gauges ought to be similarly situated. A rain-gauge must be placed in as open a position as possible, out of the way of houses, trees and similar objects that may deflect the falling drops.

RAIN-MAKING. The problem of rain-making, or bringing rain from the clouds in a season of drought, has in all ages been of the greatest interest to humanity, as lack of expected rain has assisted in producing many famines and the loss of many millions of lives. Attempts have been made to bring rain by appeals to Divine Providence in prayer in Christian countries, while the ignorant heathen practise various forms of fetishism, and even offer up human sacrifices with the same object. Owing to the large extent of arid lands in the United States the question of bringing about rain by scientific processes has often engaged attention. It was noted that forest fires have often been followed by rain, and in 1834 James P. Espy of Pennsylvania proposed the building of enormous fires in the regions where rain was desired to bring about the needed showers. This was regarded as impracticable both in America and in Australia, where it was also suggested. That great battles, and sometimes lesser ones, attended by cannonading, were occasionally followed by heavy rainfalls has long been a popular belief, and this gave origin to the opinion that explosions similar to those of artillery might bring about rain in a season of drought. This belief did not apparently take into account the circumstances that important battles are usually fought in temperate regions, with normal rainfall, and where a disturbance of the atmosphere might easily bring a downpour from the skies. It is also averred by the opponents of this theory that the number of battles followed by rain has been comparatively small; and we now know that the tremendous quantities of explosives used in the World War had no appreciable effect on rainfall. In 1891, however, Congress made an appropriation for a series of experiments in Texas, which were conducted by General Dyrenforth for the Department of Agriculture. There has been much

controversy as to the effect of these experiments which were conducted on the theory of provoking rainfall by concussion caused by explosions, giant powder being the explosive used. General Dyrenforth claimed that the experiments were entirely successful, that the drops sometimes commenced to fall within 12 seconds after the initial explosion, and that "the concussions from explosions exert a marked and practical effect upon the atmospheric conditions, in producing or occasioning rainfall, probably by disturbing the upper currents." On the other hand, Prof. A. H. Hazen, basing his views on the newspaper reports of the experiments, argued that there was no evidence whatever that any rainfall had been produced by the explosions, while W. K. Curtis, M.D., who was with the Dyrenforth party, substantially confirmed Professor Hazen's view, and declared that rain fell before the experiments had begun. The weight of evidence was generally accepted by the public as supporting the views of Hazen and Curtis, and while the theory that rain frequently follows aerial explosions has not been wholly abandoned, no serious efforts have been made to follow up the experiments of General Dyrenforth. See METEOROLOGY.

RAIN PRINTS, slight depressions made in mud surfaces by falling rain drops. They are usually formed only during showers in which but few very large drops of rain fall. If they are buried beneath drifting sand or clay they may be preserved as little pits on the surface of a rock layer, or as protuberances on the under surface of the layer above. They cannot occur in rocks laid down in the sea. They may sometimes be used to tell top and bottom of a rock layer.

RAIN-TREE, a leguminous tree (*Pithecolobium saman*) of tropical America, now largely planted in India for the shade it furnishes, and because it flourishes in barren salt-impregnated soils, as well as for its sweet pulpy twisted pods, which are greedily eaten by cattle. Another species (*P. dulce*) with edible pods is a native of Mexico, but has been introduced into the Philippine Islands and also into India.

RAINBOW. The rainbow is the best known of all optical meteorological phenomena, consisting of a colored arch formed opposite the sun on falling raindrops, and visible whenever the necessary conditions of a passing shower on one side and a clear and not too high sun on the other occur. Two bows are frequently seen, each exhibiting the full spectrum of colors from red to violet; but in the inner or primary bow the red is the outer edge and violet the inner, while in the outer or secondary bow the order is reversed, the red being inside and the violet on the exterior. The colors are always arranged in a definite order, that of the solar spectrum—namely, red, orange, yellow, green, blue, indigo and violet, but shade imperceptibly into each other. The cause of this breaking up of the sunlight into its constituent colors is explained in most physical and meteorological textbooks, but may be briefly summarized as follows:

For the primary bow (Fig. 1), let PQR represent the section of a raindrop, and SP a ray of light falling on it. The ray enters the drop at

P, meets the surface again at R, is reflected to Q, where it leaves the drop in the direction of QE. The ray is refracted or bent on entering the drop at P and again on emerging at Q—the amount of this refraction depending on the acuteness of the angle at which the ray meets the surface. Now it may be shown that there is a particular point P, such that any ray from S striking the surface below P emerges again above Q, and any ray above P also emerges above Q—the former owing to the more acute angle of the reflection, and the latter to the greater refraction on entering and leaving the drop. The course of two such rays is shown by the dotted lines in Fig. 1. Q is thus a turning-point in the emerging rays, and near it a

FIG. 1.

very large number of rays pass out, and an observer at E sees a bright image of S in the direction EQ. This statement applies to any one color of sunlight; but, as the refrangibility increases from red to violet, the latter is bent more at P and Q, and the line EQ lies at a flatter angle. The observer, therefore, sees the violet rays reflected on drops at a less altitude than those that reflect the red, the other colors being intermediate. The raindrop being spherical, this reflection takes place in all directions, the fixed condition being the radius of the bow, that is the angle between the line from the observer to the bow and that passing from the sun to the observer, or, in other words, the observer's shadow. For red light this angle is $42^{\circ} 39'$, and for violet $40^{\circ} 13'$. If the sun were a luminous point each color would be sharply defined, but as the disc of the sun subtends an angle of about $30'$ each color is broadened to this amount, and they overlap.

Exactly similar reasoning explains the secondary bow (Fig. 2). The light that forms it

FIG. 2.

has been twice reflected, at R and at R'; the point Q lies above P, and rays entering either above or below P all emerge below Q. A glance at the diagram will show that the greater bending of the more refrangible rays makes the line

EQ more nearly vertical, and, therefore, the violet rays form the outer edge and the red the inner of the secondary bow. The radius of the red is $50^{\circ} 5'$, and of the violet $54^{\circ} 0'$. The space between the bows gets no reflected light, but that inside the primary and outside the secondary is faintly illuminated by rays such as are indicated by the dotted lines in Fig. 1 and their equivalents in Fig. 2, which are not shown. These rays "interfere" with each other, and cause alternations of color which appear as spurious bows inside the primary and outside the secondary. They can only be seen with strong sunlight and small drops of rain.

The radius of the primary bow being roughly 40° , it is evident that it cannot be seen when the sun is at a greater elevation than this, as the highest part of the bow would lie below the horizon. See LIGHT.

RAINBOW ARCH, Utah, a superb natural arch of red sandstone spanning Bridge Canyon on the north slope of Navajo Mountain in the southeastern corner of the State, at a point four miles above where that canyon empties into the Colorado River 16 miles below the mouth of the San Juan River. The arch rises 309 feet from the bed of the stream below. The abutments are 278 feet apart and

Rainbow Natural Arch, Southeastern Utah.

its width on top is from 33 to 42 feet. It could easily span the dome of the Capitol at Washington and very nearly overtop the Flatiron building in New York. It has been made a national monument by the United States government. It is in a part of the Navajo country given over to the use of the Piu Indians, who called it Barohoini or rainbow. The Navajoes call it Nonnezoshe or stone

arch. Near one abutment are remains of an Indian altar doubtless built for worship of the arch, for it is held in great reverence by the Indians. The arch is eroded from buff colored fine-grained sandstone, brick red upon its surface but stained darker in vertical streaks, a part of the upper La Plata sandstone of Jurassic Age. It was discovered by W. B. Douglass of the United States Land Office on 14 Aug. 1909. The arch may be reached from Gate, Utah, 37 miles distant in a straight line, by several days of hard riding. Gate is 180 miles north of Gallup on the Santa Fé Railroad or 140 miles from Dolores, Colo. Consult Pogue, J. E. (in *National Geographic Magazine*, Vol. XXII, pp. 1048-56, 1911).

RAINBOW (42d) DIVISION, The. For a number of years before the World War discussions have periodically taken place in our newspapers whether our national guard was sufficiently efficient to be of real use to the nation. The Rainbow (42d) Division seems to be a very decisive answer and emphatically in the positive. For valor and effectiveness in the battlefields of France the ranks of the Rainbow Division take second place to none. Under authority of the Act of 18 May 1917, the 42d Division was organized in compliance with memorandum of the chief of staff for the adjutant-general of the army, dated August 1917. At its inception it contained 887 officers and 26,265 men. The division was made up of national guard troops drawn from all over the United States. It was composed as follows: Division headquarters and headquarters troop; 83d infantry brigade (165th, 166th infantry regiments and 150th machine gun battalion); 84th infantry brigade (167th, 168th infantry regiments and 151st machine gun battalion); 67th artillery brigade (149th, 150th and 151st artillery regiments, 117th trench mortar battery); 149th division machine gun battalion, motorized; 117th engineer regiment; 117th engineer train; 117th field signal battalion; 117th train headquarters and military police; 117th supply train; 117th ammunition train; 117th sanitary train. These newly-created Federal units were made up from the following national guard troops: 4th regiment infantry (Alabama); 1st separate battalion engineers (California); field hospital company No. 1 (Colorado); field hospital No. 1 (District of Columbia); Companies B, C and F, 2d infantry (Georgia); 1st field artillery (Illinois); 1st regiment field artillery (Indiana); 3d infantry (Iowa); 1st ammunition train (Kansas); 1st separate troop (Louisiana); 1st ambulance company (Michigan); 1st field artillery (Minnesota); battalion signal corps (Missouri); field hospital company No. 1 (Nebraska); ambulance company No. 1 (New Jersey); 69th infantry (New York); engineer train (North Carolina); 4th infantry (Ohio); ambulance company No. 1 (Oklahoma); field hospital company (Oregon); 3d battalion of 4th infantry (Pennsylvania); 1st battalion engineers (South Carolina); ambulance company No. 1 (Tennessee); supply train (Texas); 1st and 2d companies, coast artillery (Virginia); Companies A, F and G of 2d infantry (Wisconsin).

The headquarters of the division was organized at Camp Mills, Long Island, where it functioned for a short period. Major-General

Wm. A. Mann was in command till 14 Dec. 1917, when he was succeeded by Gen. Charles T. Menoher.

Considerable doubt was expressed by some experts as to the outcome of such an unprecedented fusion of citizens of such diversity of States into one body of fighting men, the fear of dissensions among them from local jealousies and differences of viewpoints. But the officers tell of the very pride of locality of origin made a rivalry to the Westerners to outshine the Easterners, while the South and far North joined in the determination to uphold the fame of their sections of the States. And the emulation engendered a flame of patriotism on the field of battle that allowed no obstacle to delay the brave division's advance. The insignia of the division, worn during battle, was a rainbow superimposed on a field of black, carried on the left shoulder. Certainly a perfect symbol of the complex makeup of the unit, and the blending of the prismatic many-colored rays was admirably exemplified in the concord displayed by its members. Twenty-six different States and the District of Columbia were represented at first but later replacements brought in members (by voluntary enlistment or by draft) from nearly every other State in the Union.

The first units sailed for France from Hoboken, the first ship being the *Covington*, on 18 Oct. 1917. The last units arrived in France on 7 Dec. 1917. Being already partly trained by their membership in the national guard, the term of their final practice before taking an active part in the fighting line was short. And by 27 March 1918 we are told that after "just completing a month's tour at the front" in the trenches they were assigned to occupy a sector on their own account near Baccarat. Here they maintained their front (about 15 kilometers) for three months in constant contact with the attacking Germans and suffering an average of 14 casualties per day, artillery and patrol activities on both sides being fierce in May. After the first few weeks No Man's Land in front of the combatants had become controlled by the 42d after having been dominated by the Germans till the Americans' arrival, and already Huns were being made prisoners. The division was withdrawn from this sector 21 June, and transferred to a position east of Rheims after having (as Commander Menoher later informed them in a congratulatory speech) "served continuously as a division in the trenches for a longer time than any American division." They were also the first American division to hold a division sector. And all this without previous experience in actual warfare. On their new front in the Champagne sector, under General Gouraud of the 4th French army and as part of the 21st French corps, a fierce attack in force of the Germans on the 15th July was repulsed. On the following day a terrific bombardment was followed by an infantry attack of the enemy which gained no ground but met a loss to the Germans of 27 prisoners and some machine guns, not to mention many dead left behind on their retreat. This brilliant work called for congratulations from the French commander, and, it appears, the Kaiser was present in this sector to see his 25 picked divi-

sions break through here and make their last drive on Paris. It has been estimated that altogether 5,500 cannon had been in action during the engagement. The 167th infantry and the French mortar battery (Tennessee) were conspicuous for bravery in the action. No prisoners and none missing figured in the casualties. The French mortar battery ran out of ammunition, but Captain Gill in command offered his services to the French chief in preference to retiring, for which gallant act he was later decorated by General Gouraud. In the last week of July the Rainbow Division, the German advance being checked, was withdrawn to the Chateau Thierry section to relieve exhausted divisions who had been resisting the drive of the army of the Crown Prince. They first encountered the enemy at Trugny and drove forward toward the river Ourcq, which, on the 27th, they attempted to cross, but were driven back by heavy artillery fire. On the 28th they forced the passage; by 9 o'clock in the morning reaching their objectives of the day from Hill 212, later taking Seringes-et-Nesles, Nesles and Sergy in the face of the most desperate resistance by machine gun fire and machine gun attacks from airplanes extending back as far as Forêt de Fere, as well as accurately directed artillery fire. So obstinate was the enemy's resistance that Sergy, for instance, changed hands no less than nine times before being definitely occupied by the 42d Division. The Rainbows' brave action elicited the compliments of the commander of the French corps for its speedy work that "enabled the French division on the right to advance." From a prisoner it was learned that it was the 4th German Guards Division and the 201st Division that the Rainbows crumpled up so badly. And the day's report to headquarters includes in its recital the words: "The command is in good condition and, having consolidated its lines, is preparing to advance as soon as orders are received." In spite of the fearful machine gun fire maintained by the enemy the 42d Division was moving forward by 1 August, but its advance on the 3d was stopped in line of Mareuil-Endole Coulanges by machine guns, its opposing force being identified as the 1st Guard Division. The communique of the 5th states concerning the action of 2 August: "Shortly after day-break our troops commenced their advance on the right of our line. Our only fresh troops, the 117th engineers, acting as infantry, pushed over Hill 212, which had been the scene of bloody combats during the last few days. As this regiment neared Bois de la Pissotte they were halted by machine gun fire from the southern edge of the woods. The 167th and 168th infantry were also halted by machine gun fire from the southern edge of the same woods and from Les Bonshommes and the woods to the north of it. On our left the 165th infantry and the 166th infantry, the latter in *liaison* with the French divisions to the west of us, pressed through the Forêt de Nesles and up the open field to the west of the Forêt. The 165th infantry on reaching the road Mareuil-en-Dole-les Bonshommes Ferme was halted by the enemy's artillery fire in the woods. Meanwhile, the Bois de la Pissotte and les Bonshommes Ferme had been flanked and the

enemy's machine gunners put to flight so that the troops on our right were able to advance abreast of those on our left. Our artillery followed the infantry advance and to-night all our regiments and one regiment of the 155th have crossed the Ourcq and are advancing slowly. Our most advanced elements, the 117th engineers, occupied Chéry-Chartreuve at dawn on August 3." After this unbroken spell of terrific fighting the 42d obtained a well-earned and necessary rest for a short period. But already by 12 September the gallant division and its replacements were called on for forced night marches to aid in the great effort that was to bring about the reduction of the Saint Mihiel salient. The communiqué for 22 September tells us: "We made two highly successful raids on Haumont and Marinbois farm, capturing 25 prisoners belonging to two enemy divisions. Aviation and artillery activities on both sides, enemy's artillery putting down barrage on our raiding party. Our casualties, four men killed, 15 wounded." Concerning the brilliant action of the Rainbow Division in the Saint Mihiel attack Commander Menoher says it was incorporated in the centre of the 4th army corps and: "Our men were instructed to deliver the main blow in the direction of the heights overlooking the Madine River." General Menoher thus graphically describes the wonderful activities of the Rainbow Division at the battle of Saint Mihiel: "The 42d took every objective in accordance with the plan of the army commander. They advanced 14 kilometers in 28 hours, and forward elements pushed five kilometers further, or 19 kilometers beyond their original starting point. They took more than 1,000 prisoners from nine enemy divisions, seven villages and 42 square kilometers of territory were captured by the division, and large supplies of food, clothing, ammunition, guns and engineering material were seized." The Rainbow Division's prowess was soon again called for after the extinction of the Saint Mihiel salient for it was called on before the middle of October to take its prominent place in the Meuse-Argonne front. Starting active aggression west of Montfaucon its advance was phenomenal and best described by its commander thus: "Some very desperate hand-to-hand fighting took place in the woods of the Argonne. Men even fought with their bare hands, and from tree to tree in Indian fashion, yelling at the top of their voices. Major Ross's battalion of the 168th infantry (Iowa regiment) particularly distinguished itself here. Both he and General MacArthur were cited for extraordinary gallantry in action. The 42d took Hill 288, La Tuilerie Farm and the Côte de Chatillon, and as the result broke squarely across the Kriemhilde Stellung, the last line of defense of the Hindenburg line, clearing the way for the advance beyond Saint Georges and Landres at Saint Georges. Marching and fighting day and night, the men of the Rainbow thrust through the advancing lines of the first army. They drove the enemy across the Meuse. They captured the heights dominating the river before Sedan and reached in the enemy line the furthest point attained by any American troops. The advance of the division to the outskirts of Sedan was probably one of the most rapid

ever made against opposition. The men were pushed day and night to the limit of endurance, but they responded here as they had always when called upon for extreme effort. They made 24 kilometers in 28 hours; this was done through the most difficult country and in about the nastiest weather I ever saw in my life." In his farewell address to his devoted division when, on 7 November, he left them, the general gave some of the remarkable facts concerning the exploits of the Rainbow Division in the following résumé: "Since 12 September you have taken over 1,200 prisoners; you have freed 25 French villages; you have recovered over 150 square kilometers of French territory, and you have captured great supplies of enemy munitions and material. Whatever may come in the future, the men of this division will have the proud consciousness that they have thus far fought wherever the American flag has flown most gloriously in this war. In the determining battle before Chalons, in the bloody drive from Chateau-Thierry to the Vesle, in the blotting out of the Saint Mihiel salient, and in the advance to Sedan you have played a splendid and leading part." General Menoher left his command on 7 November to become director of the air service. He received two French medals, Commander of the Legion of Honor and Croix de Guerre with palm.

The final personnel of the 42d Division consisted of the following officers: Maj.-Gen. C. A. F. Flagler, commander; Col. Wm. N. Hughes, chief of staff; Maj. James E. Thomas, adjutant; Lieut.-Col. E. J. Moran, division inspector; Maj. James C. Crossley, division judge-advocate; Capt. F. B. Verney, assistant provost marshal; Lieut.-Col. George F. Graham, division quartermaster; Col. David S. Fairchild, division surgeon; Col. John M. Johnson, division engineer; Maj. John A. Wheeler, division ordnance officer; Lieut.-Col. Ruby D. Garrett, division signal officer.

The insignia of the division, which was worn on the left shoulder during battle, is a rainbow, superimposed on a field of black. In acknowledgment of its valor and great services during the World War the Rainbow (42d) Division has received no less than 205 distinguished service crosses.

On 20 November (after the armistice) the division was incorporated with the 3d corps and entered Germany with the occupation troops 2 December. It was stationed at Ahrweiler after 18 December. In April 1919 the division started entraining for its home journey and on arrival dispersed to its many home quarters. The entire list of casualties of the 42d Division as published by the War Department to 10 January consisted of 1,702 killed in action; 723 died of wounds; 440 missing in action; 86 prisoners; a total of 2,950, not including field signal battalions and trains.

RAINBOW FALLS. See CHELAN, LAKE

RAINBOW TROUT, a fresh-water fish (*Salmo irideus*) indigenous to the mountain streams and rivers of the Pacific Coast of the United States, but widely introduced into Eastern waters. From the eastern brook-trout (*Salvelinus fontinalis*) it may be easily distinguished by its colors and the presence of teeth on the vomer bone; from the related salmon trouts, with some difficulty, by its small

mouth, and the number of scales, about 135 in typical examples, along the lateral line. The rainbow trout is exceedingly variable and many distinct forms, which are considered by ichthyologists to be modifications of this species but which have received distinct vernacular names, are found occupying particular streams or watersheds. The complex relations of the various species of trout and salmon to their environment is little understood. From fish-culturists the McCloud River trout (*S. irideus shasta*) has received much attention since 1880. This variety is particularly well adapted for stocking streams and ponds in which the brook-trout no longer thrives, owing to the clearing of the forests and the resulting higher temperature and increased muddiness of the water. To supply the great and constant demand for young fish for stocking purposes the Federal Fish Commission maintains several large hatcheries and many States, others. Carefully selected breeding fish are kept in specially constructed ponds designed with reference to cleanliness, good circulation and ease of handling the fish. Spawning occurs during the winter. The ripe females are stripped in the usual way and the eggs mixed with the milt in a pan either with or without water. After a few minutes water is added and they are gently agitated and repeatedly washed to remove the surplus sperm, and, after standing about an hour, are transferred to the hatching trays, which are constructed of galvanized wire. These trays are arranged in troughs with running water in such a way that the young fry fall into the latter as they hatch. As the fry grow and begin to feed they are distributed to other troughs and finally to rearing ponds, constructed in a manner to insure cleanliness and an abundance of flowing water. The young are fed on ground liver and are transplanted when several months old. They grow rapidly, but in the East never attain the large size which they do in their native streams. They feed on insect larvæ, etc., and may be fed artificially on chopped beef or liver mixed with corn meal. For angling purposes the rainbow is inferior to the brook-trout, but is a fair substitute.

RAINES, John, politician: b. Canandaigua, N. Y., 6 May 1840; d. 22 Feb. 1909. He was graduated from the Albany Law School in 1861, and admitted to the bar. He served in the Civil War as captain from 1861 to 1863; then began his law practice. He was a Republican member of the New York assembly in 1881-82 and again in 1885; of Congress in 1889-93; and of the State senate in 1886-89 and 1895-1909. In 1903-04 he was president pro tempore of the senate and chairman of the committee on rules. He is best known as the author of the Raines Liquor Law (q.v.), and he also framed the State Election Law.

RAINES' LAW (so called from State Senator John Raines, who introduced the measure), a law passed in 1896 by the legislature of New York, and since amended in several particulars, but always retaining the essential features of State control of the liquor traffic and high license for cities. The law permitted hotels to sell to guests on Sunday, and this has led to the establishment of numerous places known as "Raines' Law Hotels," which comply with the strict letter of hotel regulations, but do

what is chiefly a liquor saloon business. The law brought large returns in money for city and State, the city receiving two-thirds and the State one-third of the net income from licenses, but it was generally conceded that this was at the expense of good morals. See LICENSE.

RAINEY, Paul J., American explorer and big game hunter. A man of wealth, he traveled and hunted in the Rocky Mountains, the Arctic region and in Africa and India. He became prominent through the motion pictures of wild life in the jungles of Africa and India which he succeeded in taking during his expeditions of 1910 and 1914 and which attracted worldwide interest. He has contributed to *Outing*, the *Scientific American Supplement* and other periodicals.

RAINFALL. Rainfall or precipitation, the generic term applied to the condensation of aqueous vapor into cloud, fog, dew, rain, snow, frost and hail, varies greatly in the several zones and in the successive seasons and at different altitudes. Temperature, by which is meant the temperature of the air at a given place and elevation, is one of the controlling physical factors in determining its annual rainfall or precipitation. The atmosphere, consisting according to Prof. Julius Hann of the University of Vienna of the following elements and proportions, nitrogen 78.03, oxygen 20.99, argon 0.94, carbon dioxide 0.03, hydrogen 0.01, neon, 0.0015 and helium 0.00015 parts and subject to rapid and continual changes in temperature, largely conditions precipitation over the earth, itself, owing to its varying topography, one of the controlling factors in the problem. The vast expanse of oceans, seas, gulfs and inland waters and the uplift and extent of its various mountain ranges and the expanse and location of its continents in their relation to oceans and to the torrid, temperate and frigid zones, together with the rotation of the earth on its axis and its revolution around the sun, produce different atmospheric conditions, conducive to great variation in precipitation. Furthermore the atmosphere rapidly decreases in density upwards from the surface of the earth and solar radiation likewise decreases in its intensity. The sun's rays penetrate the atmosphere at various angles and these are continually changing so that the amount of radiant energy is neither constant nor uniform in the different latitudes and seasons. Owing to these physical conditions and the inclination of the earth's axis to the plane of the ecliptic, producing unequal day and night in the four seasons, there are ceaseless movements in the atmosphere itself, such as currents, winds and storms, that affect its humidity and the amount of rainfall. Both terrestrial and solar disturbances affect the atmosphere and the amount of rainfall. In some localities periodic winds prevail with such constancy that they are denominated by such terms as "trade winds," "monsoons," "land and sea breezes" and some ocean currents are no less constant. All these and other physical phenomena must be considered in accounting for precipitation and its variation in different localities.

Evaporation is the physical transformation of solids and liquids into gases, due to the kinetic energy of their molecules to diffuse themselves through space. Heat increases that

energy of the molecules of water in whatever form it may be, though the coefficient of diffusion for aqueous vapor is greatest at the earth's surface. Professor Cleveland Abbe of the United States Weather Bureau has said that "the vapor constituent of the atmosphere is not distributed according to the law of gaseous diffusion, but like temperature and the ratio between oxygen and nitrogen, is controlled by other laws, prescribed by the winds and currents, namely—convection." That may be either horizontal, due to the winds, or vertical, due to upward or downward currents. Temperature is also one of the most important factors in the problem of evaporation and in the distribution of aqueous vapors. Atmospheric pressure is another important factor in the problem. Atmospheric gases retard the diffusion of aqueous gases and act independently of each other. Professor Adolph F. Meyer of the University of Minnesota states that "water in the gaseous state has a specific gravity of .622, as compared with dry air," and that "the pressure of water vapor at a given temperature is greater than the pressure of an equal amount of dry air at the same temperature," so that when dry air is displaced in part by aqueous vapor, the weight of the cubic content is reduced. Professor Meyer maintains that when water at 212° F. passes into a gaseous state, it increases in volume 1,658 times and stores up 970 British thermal units of heat for each pound of water so transformed. The United States Weather Bureau gives the elastic pressure of saturated vapor at 32° F. as 0.180 of an inch of barometric pressure, at 68° F. as 0.684 of an inch of barometric pressure, at 100° F. as 1.916 inches of barometric pressure and at 110° F. as 2.576 inches of barometric pressure. It thus appears that vapor pressure increases much more rapidly than does temperature. Professor Meyer also states that "at ordinary open air temperatures, the elastic pressure" (also known as "vapor tension" and "gaseous pressure") "of saturated water vapor is substantially doubled for every 20° F. increase in temperature," and "at a given temperature and pressure only a certain definite amount of water can occupy a given space and as soon as the space is saturated with moisture, dew will be deposited." Then heat is liberated, which tends to retard a further fall in the temperature. The higher the temperature at sea-level, the greater may be the amount of aqueous vapor and stored-up heat and the slower will be the condensation and cooling. In the heat of summer, the air rises, expands, cools and as it does so, it loses its capacity to hold vapor and condensation may ensue. Professor Meyer says that "If the temperature of the vapor is 68° F. it will cool 1° in rising 425 feet." The heat so liberated warms the surrounding atmosphere and tends to prevent further condensation, so summer showers are often of short duration.

The atmospheric pressure at the level of the sea is 14.7 pounds per square inch, which is equivalent to a column of pure water at 39.2° F. 34 feet in height. That pressure decreases one pound for the first 1,880 feet, and two pounds for the first 3,900 feet, and three pounds for the first 6,080 feet above the level of the sea, and so on until it becomes negligible. The United States Weather Bureau has compiled

statistics giving the weight of a cubic foot of aqueous vapor of different percentages of saturation and at various temperatures at the level of the sea. At 32° F. a cubic foot of aqueous vapor ranges from 211 grains with 10 per cent saturation to 2.113 grains with 100 per cent saturation. At 68° F. a cubic foot of aqueous vapor ranges from .748 grains with 10 per cent saturation to 7.480 grains with 100 per cent saturation. At 100° F. a cubic foot of aqueous vapor ranges from 1.977 grains with 10 per cent saturation to 19.766 grains with 100 per cent saturation. At 110° F. a cubic foot of aqueous vapor ranges from 2.611 grains with 10 per cent saturation to 26.112 grains with 100 per cent saturation. Vapor is saturated, when it is at the point of condensation and evaporation goes on as long as there is any deficit below 100 per cent of such saturation. From the foregoing meteorological compilation, it will appear that the point of saturation and weight of aqueous vapors per cubic foot vary greatly at different temperatures. The matter under this sub-title is involved in the problems of WATER SUPPLY and will receive further consideration under that title in a succeeding volume of this encyclopedia.

Controlling Factors in Rainfall.—At sea-level in the tropics over such large bodies of water as the Indian Ocean, the amount of aqueous vapor moving vertically upward may exceed the quantity in a column of air over the Arabian and Sahara deserts. Still the vapor contents of the air over Siberian and Libyan deserts average nearly as much as that of the air over Vienna and Paris. The heat prevents its condensation. Were it cooled, it would produce normal rainfall. Humidity is the amount of aqueous vapor in the atmosphere, as compared with the amount of such aqueous vapor in it, when the atmosphere at a given temperature is 100 per cent saturated. Humidity, therefore, is relative and in some zones and localities it varies inversely, as the temperature, especially where there may be a lack of moisture as there is east of the Rocky Mountains and over the desert regions of the earth. When water is vaporized, pressure is exerted on atmospheric gases. Thus both vertical or convective currents may be generated, clouds may be formed and heavy rainfall may ensue, as a result of the cooling of the saturated water vapor in the upper strata of the atmosphere. The heat, liberated in the cooling process, retards the condensation and checks the rainfall. A rising barometer indicates the absence of vapor pressure, the expansion of dry air, slight evaporation and no rainfall. Humidity, temperature, topography and the physical phenomena already mentioned are factors more or less controlling, in the problem of rainfall over a given territory. There are others, such as the contour of the territory, its elevation above the level of the sea, the extent of its forests, the configuration of its mountains, the influence of continents upon humidity and character of its seasons. Notwithstanding the complexity of the phenomena, conditioning rainfall or precipitation, the same has been observed over long periods and reduced to mean annual tabulations. There have also been deduced formulæ to ascertain the presence and amount of evaporation, which, to slight extent only,

indicates the amount of rainfall or precipitation, for the former may be both a contributing cause and one of the results of the latter. Dalton, Bigelow, Russell, Meyer and others have proposed evaporation formulæ to determine evaporation under various conditions of humidity, temperature, wind velocity, vapor tension and barometric pressure. The results obtained from the application of such formulæ are not identical, nor do they always conform to actual measurements, which are difficult to make.

The United States Weather Bureau and the climatological stations of some other nations have compiled statistical tables of evaporation over various land and inland water areas, but not over oceans, seas and gulls, which altogether cover three-fourths of the surface of the earth. From all such bodies of water evaporation is continuous and the greatest. These great fountains of the deep supply the vapor-laden clouds, which are swept landward and release their waters in refreshing rains, wintry snows or in some other form of precipitation. Frequently such vapor-bearing clouds are swept against mountain ranges, as those rising from the Mediterranean Sea are swept against the Alps and those rising from the Pacific Ocean against the Andes Mountains. In some regions precipitation is much greater than it is in others, and over the same region it varies greatly in different years. That is due to the operation and effect of the physical conditions already stated. However, over cycles of years it is quite uniform, as will hereinafter appear. Deforestation decreases and reforestation increases the general average. Forests promote rainfall, retard evaporation and run off and store up precipitation in pools, ponds and lakes, some of which are the sources of streams and rivers. The United States and many other nations have bureaus, or departments devoted to scientific forestry, one of the most important and necessary functions of government, if the habitable areas of the earth are to be preserved. Deforestation and consequent lack of rainfall have rendered many once populous areas now uninhabitable, as indicated in this article. This and other generations ought not to neglect a matter of such vital importance to themselves and to succeeding generations, but ought to enter upon the systematic reforestation of all properly available areas.

Regional Precipitation.—The amount of precipitation, over many portions of the habitable earth, has been observed for long periods substantially as follows: In the polar regions there is no rainfall. Precipitation there is congealed in snow and icy particles. In the tropics there is little snow except on the highest mountains and most precipitation is in the form of rain. In the upper latitudes of the temperate zones there are both rain and snow. Over the Sahara, Arabia and other desert regions and in the desert regions in Australia and South America there is but little precipitation, while along windward coastal regions the annual precipitation is abundant, as found along the Atlantic and other continental coasts facing eastward. Usually those sides of mountain ranges that face oceans, or large bodies of water, have a much larger rainfall than do the opposite sides, which face inland areas. There

is more rainfall on the slopes of the Sierra and Coast ranges where many glacial lakes and ponds exist in the ranges themselves, such as Tahoe, Clear Lake and others, than there is rainfall on their eastern slopes. East of some of these and of the Rocky Mountains the annual precipitation is light and large desert areas had existed, but for irrigation. No one law has been deduced from all these varied phenomena, affecting precipitation over all parts of the habitable globe to determine its amount. Much data has been collated from actual measurements. Some of these will indicate the amount of precipitation in those regions and at various altitudes.

E. S. Bellasis, sometime engineer of the Public Work in India, in substance stated that "the rainfall in India varied from 2 or 3 inches in Scinde to 450 inches at Cherrapunji in the eastern Himalayas and that at two stations in the Bombay hills, only 10 miles apart, the annual rainfall were respectively 300 inches and 50 inches and that in England at Hemstanton, it was about 20 inches, while at Seathwaite it was about 200 inches." He stated that "the annual rainfall at Mercara in South India was 119 inches, in King William's Town in Cape Colony 27 inches, at Melbury Moor, in England 50.7 inches, at Newport in the Isle of Wight 32 inches, in the basin of the Cataract River in New South Wales from 33.7 inches, in 1896, to 56.4 inches, in 1898 in the basin of the Nepean River in New South Wales 44.3 inches and in 1905 in the valley of Sudbury, Mass., 42.3 inches."

The water supply of a country is largely conditioned upon its water resources and the latter are dependent to a large extent upon its rainfall, or rather precipitation, which includes rain, hail, sleet and snow. The amount of annual precipitation over a given territory in successive years is not constant, nor is it uniformly distributed, except over a few such States as Wisconsin and Michigan, and over some foreign limited districts.

The annual precipitation in the State of Washington ranges from 12 to 120 inches in different localities, though in Seattle for a period of 19 years it averaged 38.8 inches. In different parts of Oregon it ranged from 8 to 138 inches and in Texas from 9.3 inches at Pasco to 48.2 inches at Houston. Nor is the annual precipitation over a locality constant from year to year. The Weather Bureau's report shows that the precipitation at Dodge City, Kan., has ranged from 9.9 to 33.7 inches. There are dry and wet years as there are dry and wet seasons. In the drought of 1894 and 1895, the deficiency in precipitation measured in the upper Mississippi Valley from 7.8 to 12 inches, in New England from 5.3 to 8.1 inches and in the south Pacific watershed from 4.4 to 4.6 inches. In three months of 1905, there was an excess of 2 inches in the rainfall at Yuma over its mean annual precipitation. In 1900, the rainfall at Bay Saint Louis, Miss., was 101.5 inches which was an excess of about 50 inches over normal precipitation for the State. The difference between the maximum and minimum rainfall on the Croton watershed (New York) in a period of 43 years was 26.8 inches and in Pittsburgh (Pa.) that difference was 25.3 inches in a period of 71 years.

Mean Annual Precipitation in the United States and Canada.—The United States maintains several hundred observation stations in addition to those maintained by the States themselves and by individual and corporate enterprise, where meteorological and climatological observations are made and for half a century have been made and records kept of the annual precipitation at those stations. From all such official and authentic observations and the computations made therefrom, climatological tables have been compiled, showing in most cases over periods of years the mean annual precipitation at scores of stations in the United States. Foreign countries have made similar observations and records. In nearly all of the tables, the measurements are the resultant of many observations and are denominated "the mean annual precipitation."

From such official and from other well-authenticated measurements, the writer has selected some and averaged others from approved records to ascertain and state the mean annual precipitation over the United States and Canada. The following represent the mean annual precipitation over the localities mentioned, or they are aggregated from a number of stations over large areas, showing such precipitation. Many of these are from the reports of the United States Weather Bureau, extending over a number of years and others from authentic data. The mean annual precipitation in the coastal region of Alaska varies from 60 to 110 inches.

United States.—The greatest annual precipitation in the United States is over the western slopes of the mountains forming the Continental Divide which intercept the vapor-laden clouds from the Pacific and precipitate their moisture in some localities to an average of 70 to 135 inches.

ALABAMA.—The United States Weather Bureau gives the mean annual precipitation, as measured at 15 stations, as 52 inches, at Montgomery it is 50.8 inches and at Mobile 62.1 inches.

ARIZONA.—Along the Colorado it is less than 3 inches, at Phoenix 7.4 inches, at Fort Grant 15 inches and at Flagstaff 22 inches.

ARKANSAS.—It averages 46.7 inches, being 49.6 inches at Little Rock, 55.2 inches at Helena and 41.8 inches at Fort Smith.

CALIFORNIA.—It ranges from 32.2 inches over the Sacramento watershed to 10.2 inches at San Diego. Professor Meyer states that it averaged 9.6 inches at San Diego for a period of 65 years. At Berkeley it is 26.47 inches, at San Francisco 23 inches and at Los Angeles 17.6 inches.

COLORADO.—It is variable. At Denver it is 14.7 inches, at Pueblo 11.6 inches, at Orchard 17 inches and at Long's Peak 16.7 inches. In other sections it varies from 7.01 to 26 inches and over Colorado River watershed it is 17.7 inches.

CONNECTICUT.—At Hartford it was 44.50 inches, at New Haven 47.2 inches, at New London 48.08 inches and at Waterbury 49.9 inches.

DELAWARE.—At Millsboro it was 47.3 inches.

FLORIDA.—There is annual precipitation over the State as determined at 13 stations of 54.53 inches. At Tampa it is 53.1 inches, at Key West 37.9 inches, at Miami 58.3 inches and at Jacksonville 53.4.

GEORGIA.—The United States Weather Bureau reported in 1906 that the annual precipitation in the northeastern part of the State was 54.1 inches, in middle Georgia 49 inches, in southeastern Georgia 50.7 inches, at Atlanta, for a period of years, it averaged 49.2 inches, at Savannah 48.67 inches and at Clayton 68.5 inches.

IDaho.—It varies from 6.3 to 40.4 inches, but in most sections it ranges from 12 to 13 inches.

ILLINOIS.—It averages 36.5 inches. At Chicago for 40 years it averaged 33.5 inches. At Springfield it is 37.4 inches and at Cairo 41.6 inches.

INDIANA.—The mean annual precipitation over the State is 38.4 inches. At South Bend it is 34.5 inches, at Indianapolis 41.9 inches and at Marion 37 inches.

IOWA.—From the measurements at 46 stations scattered over the State, the United States Weather Bureau reported the mean annual precipitation over the State to be 31.5 inches, at Keokuk it was 35.1 inches and at Sioux City 25.8 inches, at Iowa City in 1890, it was 58 inches.

KANSAS.—Measured at 19 stations, it averaged 27.3 inches, at Garden City it was 19.6 inches, at Wichita 30.4 inches, at Atchison 37.1 inches and at Topeka 34.1 inches.

KENTUCKY.—At 10 stations it ranged from 42.5 inches at Lexington to 50.3 inches at Wimblesboro. At Louisville it is 44.5 inches.

LOUISIANA.—There is great variation in the yearly rainfall. In New Orleans the annual rainfall has been as low as 31 inches and as high as 85.6 inches. For 67 years it averaged 56.1 inches. It ranges there from 55.4 to 62.6 inches and over the State from 46 inches over the southern stations to 55 inches over the eastern.

MAINE.—At Portland it was 42.8 inches, at Lewiston 46.2 inches, at Eastport 43.4 inches, at Bar Harbor 48.9 inches, at Mayfield 52 inches.

MARYLAND and DELAWARE.—The annual precipitation ranges from about 44 inches in the former to 47.3 inches in the latter. At Baltimore it was 43.4 inches, at Washington and District of Columbia 43.1 inches, in the valley of the Potomac 35.28 inches. Other unofficial records give annual precipitation at Baltimore as 40.7 inches, at Washington as 40.7 inches and in the District of Columbia at 38.77 inches.

MASSACHUSETTS.—At Boston it ranged from 43.7 to 45.3 inches, at New Bedford from 46.4 to 47.9 inches, at Blue Hill Meteorological Observatory 47.2 inches, at Williamstown 39.41 inches, at Lawrence 43.1 inches, at Fitchburg 45.4 inches, at Amherst 46.3 inches, at Nantucket 36.5 inches, over the Wachusett watershed 47.1 inches and over the Sudbury watershed 45.3 inches.

MICHIGAN.—It averages 32.91 inches and is similarly distributed. At Detroit it has averaged 32.1 inches over a period of 40 years.

MINNESOTA.—It averages 26 inches, while at Duluth it is 29.5 inches, at Saint Paul 28.68 inches, over the Crow Wing Valley 30.81 inches and over Croix Valley 32.58 inches. Professor Meyer gives the mean annual rainfall at Saint Paul for a period of 78 years at 27.3 inches.

MISSISSIPPI.—The mean annual precipitation is about 50 inches. In the Yazoo Valley it is 48 inches, at Natches 50 inches and at Vicksburg 53.8 inches. Over the Tombigbee watershed for a period of 50 years it has averaged 49.2 inches.

MISSOURI.—It ranges from 34 inches in the northwestern counties to 46 inches in the southeastern counties. It averages 39.9 inches at Saint Louis. The general average over the State is 39 inches.

MONTANA.—It ranges from 11.8 to 18.5 inches. At Kipp it is 18.5 inches, at Glendive 15.9 inches, at Butte 12.2 inches and at Great Falls on the Missouri 13.4 inches and at Havre 13.5 inches.

NEBRASKA.—As determined at 6 to 12 stations it averaged 23.5 inches and was principally in rain. At Omaha it was 30.8 inches, at Lincoln 27.7 inches and at North Platte 17.9 inches.

NEVADA.—It ranges from 10.8 inches at Carson City to 11.2 inches at Pioche, but varies in most parts of the State from 3 to 12 inches. At Reno it measures 7.52 inches.

NEW HAMPSHIRE.—At Bethlehem it was 37.7 inches, at Plymouth 42.4 inches, at Concord and at Keene 40.4 inches and at Nashua 43 inches.

NEW JERSEY.—The annual precipitation is 47.7 inches over the State. At Dover it is 51.2 inches, at Asbury Park 48.1 inches and at Atlantic City 42 inches. Over the Pequannock watershed it is 50.1 inches and over the Hackensack River 46.15 inches.

NEW MEXICO.—It varies from 7.2 to 15.8 inches, though there it has had a precipitation of 25 inches. At Sante Fe' it is 14.2 inches. There is slight snowfall, though the State's highest peaks in the north are snow-capped much of the time, and those snows are its principal sources of water supply. Similar conditions prevail in some of the Rocky Mountain States, affording their principal water supply.

NEW YORK.—The mean annual precipitation at the United States Weather Bureau stations over the State for 25 years averaged 39.26 inches. Over Suffolk County it averages 45 inches. Over Long Island for 67 years it has averaged 42.56 inches, at New York City 42.87 inches, over the lower Hudson 44.93 inches, at the Croton Dam from 44.93 to 50.38 inches, over the Esopus watershed 46.6 inches, at Oxford 45.4 inches, at Albany 34.84 inches, at Little Falls 54 inches, at Utica 42.29 inches, at Binghamton 36.98 inches, at Elmira 33.23 inches, at Mount Hope 27.77 inches, at Ithaca 33.97 inches, at Cortland 44.7 inches, at Rochester 33.61 inches, at Buffalo 36.71 inches, at Oswego 36.57 inches, at Ogdensburg 30.7 inches, at North Lake 55.7 inches and over northeastern New York 38.97 inches. Over the Taconic quadrangle it is 42 inches.

NORTH CAROLINA.—The resultant of measurements at 23 stations was 52 inches. In the western counties occasionally it ranges from 70 to 100 inches, thereby becoming known as a region of extraordinary rainfall.

NORTH DAKOTA.—The mean annual precipitation is from 17 to 18 inches over the State. At Bismark it is 18.8 inches. High winds blow away much of the snows of winter.

OHIO.—This State has an annual precipitation of 38.4 inches, varying from 30.8 inches at Toledo to 42.1 inches at Marietta. At Ports-

mouth it averages 41.1 inches. Over the Ohio River during a long period it varies from 32.07 to 45.79 inches and over the Muskingum watershed it averages 40 inches. At Cleveland it is 35.6 inches, at Columbus 37.2 inches and at Cincinnati from 38.4 to 45 inches. Professor Meyer states that it averaged there 40.7 inches for a period of 80 years.

OKLAHOMA.—It was computed by the United States Weather Bureau from the measurements of 10 stations and found to average 31.7 inches, with great variations in succeeding seasons and different years.

OREGON.—It ranges from 8 to 138 inches and at Portland it ranges from 45.9 to 78.2 inches. At Astoria it is 77.2 inches.

PENNSYLVANIA.—The resultant of the measurements of 16 stations is approximately 44 inches. At Erie it is 39.2 inches, at Pittsburgh 36.4 inches, at Harrisburgh 38.1 inches, at York 41.9 inches, at Mauch Chunk 50.5 inches and at Philadelphia 40.6 inches.

RHODE ISLAND.—At Providence it was 44.6 inches, but by the records for 79 years it averaged 45 inches. At Narragansett Pier it was 47.4 inches and at Rock Island 45.3 inches.

SOUTH CAROLINA.—It was estimated from measurements at 12 stations to be 49 inches. Monthly rainfalls in some localities and years have equalled 12 inches for a short period.

SOUTH DAKOTA.—It averages 20.3 inches, but only 1 to 2 inches fall in the form of snow.

TENNESSEE.—It averages over the State as measured at 18 stations about 50 inches, including 8 inches of snow. At Nashville it is 48.5 inches, at Memphis 50.8 and at Chattanooga 51.6 inches.

TEXAS.—The mean annual precipitation averages 30.9 inches over the entire State as determined at 19 stations, varying from 9.3 inches at Pasco to 48.2 inches at Houston. At Port Davis for 46 years it was 18 inches. At El Paso for 36 years it averaged 9.6 inches.

UTAH.—It averages 11 inches, ranging from 6.1 inches at Saint George to 16.2 inches at Salt Lake, which is mostly snow.

VERMONT.—At Burlington 33.3 inches, at Rutland 36.54 inches, at Saint Johnsbury 35.6 inches, at Northfield 33.1 inches, at Woodstock 37.3 inches and at Jacksonville 50.3 inches.

VIRGINIA.—It averaged from the measurements of 15 stations from 39.4 inches at Warsaw and Blacksburg to 50.5 inches at Big Stone Gap. At Rutland it measured 43.6 inches, at Fort Republic 38.77 inches, at Roanoke 39.09 inches and at Norfolk 50 inches.

WASHINGTON.—In the northwestern part it ranges from 12 to 120 inches, and between the Olympics and Cascade mountains it ranges from 25 to 60 inches. At Seattle for 19 years it averaged 38.8 inches.

WEST VIRGINIA.—There are 14 stations distributed over the State and the average of their measurements is 42.48 inches. Over the high plateaus the annual precipitation ranges from 45 to 50 inches, while over the lower levels along some rivers it ranges from 35 to 40 inches. Over the Greenbriar it is 44.48 inches.

WISCONSIN.—The mean annual precipitation is 31.5 inches and is uniformly distributed over the State; at Milwaukee it is 31 inches.

WYOMING.—It averages 13 inches, ranging

from 8 inches in some places to 20 inches in the Yellowstone Park.

Along the Appalachian altitudes from New York to the Gulf of Mexico there is a greater precipitation than there is at lower levels along the Atlantic Coast. From the United States Weather Bureau reports of the mean annual precipitation, measured at several stations in each New England State over a period of years, it appears that it averaged in Maine 44.6 inches, in New Hampshire 40.6 inches, in Vermont 38.2 inches, in Massachusetts 44.6 inches, in Rhode Island 49 inches and in Connecticut 47.2 inches.

Canada.—In Canada it varies in the western, central and eastern provinces as it does in the United States. At Victoria it averaged 37.77 inches, at Port Simpson 94.63 inches, at Regina 9.03 inches, at Prince Albert 14.45 inches, at Winnipeg 19.53 inches, at Port Arthur 23.58 inches, at Toronto 33.94 inches, in Quebec 28.76 to 41.5 inches, in New Brunswick 32.6 inches with 97.5 inches of snow, in Nova Scotia 39.6 inches and 77.5 inches of snow.

Latin America.—In other countries of the western hemisphere records of precipitation are meagre. However, the unofficial reports indicate that the annual precipitation is abundant for the water supply of all the principal cities whether or not they be located on lakes, rivers and other fresh waters. In Mexico, at Vera Cruz, it measured 183 inches as maximum rainfall. In Central America precipitation varies greatly in different sections. Rainfall in the latter ranges from 50 to 200 inches annually. In Cuba at Havana it ranges from 40 to 80 inches. There is a great variation of precipitation in South America owing to its physical formation with the lofty Andes extending along its entire western border and their many lateral ranges, its high arid plateaus and swampy regions, its vast area extending from 12° north latitude across the equator to 55° south latitude and from 35° to 82° west longitude, its tropical heat over most of it and its wintry climate in some other localities and its general location with reference to the Caribbean Sea, the Atlantic and Pacific oceans. The climate is as variable as all such physical conditions can produce. Generally speaking, the precipitation is not only abundant for its water supply in most of its coastal regions, but over some areas it is excessive. Over its interior elevated districts it is slight and great desert regions exist in Brazil, Bolivia, Peru, Argentina and Patagonia, where there is but little precipitation. The annual precipitation at Bogotá is 44 inches, along the coast 73 inches, at Carácas from 24 to 34 inches, at Valdivia 108 to 115 inches, in Uruguay 43 inches, in Argentina from 2 to 63 inches and in Patagonia from 19 to 97 inches. In many parts of Brazil there is heavy rainfall and in other mountain sections there are heavy snowstorms. At Rio de Janeiro it is from 43 to 59 inches, at Blumenau 53 inches and at Ceará 60 inches. The precipitation is abundant in most of the Western States, where high mountains intercept the vapor-laden winds from the Pacific. There are many large lakes high above sea-level, one of them being Lake Titicaca, with an area of 5,000 square miles, 12,545 feet above the sea. It falls in rain and snow and not only waters vast areas but supplies the headwaters of the Amazon and other great rivers.

Europe.—In Europe a few measurements will illustrate the mean annual precipitation. In England the annual precipitation varies from 25 inches or less at the mouth of the Thames to 60 inches in the lake district and in a part of Wales, while in other districts it is 40 inches. In the western counties of England near high hills it ranges from 80 to 150 inches, while in other sections it averages from 30 to 45 inches. In the eastern counties it ranges from 20 to 28 inches. The mean annual rainfall on the Vyrnwy watershed is 65.16 inches. At Litton in Bristol watershed for 58 years it averaged 41.1 inches and at Bristol 30.9 inches. Over the Thames area for 21 years it averaged 26.9 inches. Over Derwent Valley it varies from 35 inches in the south to 61 inches in the north. Over the Sheffield waterworks catchment areas precipitation averaged about 47 inches. The average rainfall over the whole of England is about 30 inches.

In the west of Scotland it ranges from 39.37 to 100 inches while in the eastern counties it is only 26 inches. At Ben Nevis it is 151 inches. Over Edinburgh district waterworks for 6 years precipitation averaged about 48 inches. Over the headwaters of the Usk, Wye and Towy rivers in Wales rainfall ranges from 45 to 75 inches per annum. In Ireland there is heavy precipitation near the high hills in the west though less than in the Highlands of Scotland. Its general average is more than it is in the eastern districts of England. Over the valley of the river Vartry the annual rainfall averages 48.82 inches. In Norway the annual precipitation varies from 12 inches at Dovre Fjeld to 83 inches between Bukken Fjord and Nordfjord. At Bergen it ranges from 73 to 89 inches. In Sweden the annual rainfall ranges from 12.32 inches at Karesuando to 45.82 inches at Cattagat. In Denmark the annual precipitation ranges from 21.58 to 27.87 inches. In Holland it averages 27.99 inches. At Utrecht it is 27.5 inches and at Tilburg it is 27.6 inches. At Amsterdam and The Hague it averages 27 inches. In Belgium the precipitation is approximately 28 inches. At Brussels it is 27.6 inches. The annual precipitation in France averages about 32 inches. For many years it averaged at Marseilles 20.75 inches and at Nantes 35 inches. Over the Rhone it ranges from 20 to 63 inches, averaging 36.32 inches. Over the Meuse it is 28.33 inches, over Yonne 30.80 inches, and over the Seine 22.7 inches. In the south of France precipitation is less than it is along the Atlantic Coast. In Switzerland the annual precipitation has been 21.7 inches, at Sierre, 32.7 inches, at Geneva, 36.6 inches, at Berne, 42.6 inches, at Montreux, 48.7 inches, on the great Saint Bernard, 65.4 inches, at Lugano, 87.3 inches, on San Bernardino Pass, 89.7 inches of rain and snow in the Alps, facing north or south, thereby intercepting vapor-laden winds from the Arctic Ocean or from the Mediterranean Sea. In the valley of the Inn River it ranges from 22.43 to 57 inches. Scores of glaciers are found in the great elevated valleys of the Alps, and these feed the Rhine, the Rhone, the Po and the Inn rivers and their tributaries. The snows and glaciers cover the high ranges and intervening valleys, whose uplift resembles the foaming billowy ocean. At Saint Maria in the Alps the precipi-

tation is 104.35 inches. In Germany it ranges from 20 to 34 inches. At Berlin it is 22.8 inches. Over the Moselle it is 29.48 inches, over the Rhine 36.69 inches, over the Main from 16 to 27.44 inches and over the Oder 24.60 inches. For 10 years it averaged 47.1 inches over the Mangfall Valley near Muhlthal. In Austria the annual precipitation ranges in various sections from 20.24 to 60 inches, and on the Dalmatian Coast it has been as high as 177 inches. At Vienna for 34 years it averaged 23.42 inches. In Hungary it averages 24 inches, at Budapest 34.32 inches, at Zagrab 70.39 inches, at Fiume and over the mouth of the Danube it is 35.12 inches. In Russia, where there are many mountains, high plateaus and extensive plains facing the Arctic Ocean, there is precipitation in the form of much snow, but not extensive rainfall. The average rainfall in Archangel is 16.2 inches, in Helsingfors, Finland, 19.6 inches, in Petrograd 18.3 inches, in Dorpat 24.9 inches, in Moscow 23 inches, in Warsaw, Russia, 22.8 inches, in Odessa 15.6 inches, at Batum 93 inches, at Sochi 80 inches, in Poti 64.9 inches; while in Astrakhan it is only 5.7 inches and over the plains of Russia but 20 inches. In Portugal, whose westerly coast is exposed to the winds of the Atlantic, there are heavy fogs and precipitation in the north occasionally amounts to 192 inches, while in the interior and in the south there is far less rainfall. In Spain rainfall averages at Madrid 15 inches, at Salamanca 11.3 inches, at San Fernando 30 inches, at Bilbao 46 inches, at San Diego 66 inches, at Oviedo 74 inches and over large areas there is but little precipitation and intense heat. Italy has moderate precipitation. The Alps in the north and its Apennines, extending nearly its entire length, intercept the vapor-laden winds of the Mediterranean and Adriatic seas. It projects southerly into warm latitudes and has a hot summer climate. Over it in the classic ages Jupiter Pluvius reigned from sea to sea. Precipitation varies from 36 inches in the north to 20 inches in the south of Italy. In Sicily it averages 15 inches. Sunny Italy is characteristic of its central and southern sections, where there is infrequent and scanty rainfall in summer months. Over the Po the rainfall ranges from 30 to 48 inches and snow in the north and mists along the coast are not uncommon. The precipitation at Tolmezzo is 96 inches. In Lombardy precipitation averages 22 inches, and irrigation canals are necessary to supply the lands with sufficient water for agricultural purposes. Nearly all Italian cities are supplied with water from rivers and mountain or ground sources. Aqueducts and infiltration tunnels through tufa without linings have long been in use to maintain such supplies. Through such tunnels 22 gallons per second are delivered at Mazzara and 40 gallons per second at Zappulla in Sicily.

Dr. Angot calculated the rainfall by months at Rome and found the annual precipitation there to be 12.03 inches and at Milan to be 12.01 inches. In Greece the annual precipitation ranges from 16.1 inches in Attica to 53.34 inches in the Ionian Isles. Olympian Zeus presided over atmospheric changes and his chief weapon was the thunderbolt. The Grecian states are well watered. In Bulgaria the mean annual precipitation is 29.59 inches. In Rumania rainfall ranges from 15 to 20 inches. The water

supply of Constantinople is from streams, springs and rainfall in the forests where reservoirs impound the waters that are conducted in aqueducts, one of which was built during the reign of Constantine.

Several rainfall maps of Europe have been made and these may be consulted for further information on this subject. However, it may be stated that all western and northern Europe are abundantly supplied with copious rains and all the mountains with heavy falls of snow that supply the headquarters of its large rivers flowing to the salted seas on the north, west and south. They supply populous areas in many parts of Europe.

Africa.—In the continent of Africa precipitation ranges from 1.5 inches in Egypt to 20 inches on the southwestern coast and to heavy rainfall in its tropical areas. In Abyssinia it ranges from 30 to 40 inches supplying some tributaries of the Nile. Along the southeastern coast facing the Indian Ocean the rainfalls is 50 inches while in the interior of South Africa it ranges from 5 to 24 inches and at some places on the east coast it is only 40 inches. At Johannesburg, it averages 30 inches, at Paarl and Weltevreden in Cape Colony it averaged for 14 years 34.67 to 35.97 inches. The annual rainfall at Durban is 42.46 inches and at East London, South Africa, it is 62.11 inches. Heavy fogs dampen some areas where there is but little rainfall.

Asia.—In Arabia are great waterless deserts while in some mountain areas living springs of water are found. There is some rainfall in northern and central Arabia. At Dhala in 1892 there was over 18 inches, while at Aden it averaged 2.97 inches. Sir A. Houtum-Schindler found the mean annual rainfall at Teheran for 15 years to average 9.86 inches and reported that at 15 stations in Persia for various years it ranged from 3.24 inches at Jask to 56.45 inches at Resht. The average at all these sections was about 17 inches.

Asia presents so many physical formations of mountain ranges, elevated plateaus, great river basins, extensive arid regions, varying climates and oceanic influences as to cause excessive precipitation of rain and snow in some great mountain areas and little in some other sections. Only a few measurements can be given. The mean annual precipitation over the Caspian watersheds is 7 to 8 inches, over the Aral Sea 6 inches, in western Syria facing the Mediterranean a moderate rainfall, at Beirut it is 21.66 inches, at Jerusalem, 36.22 inches. The normal rainfall over Palestine is about 28 inches, while in the vicinity of the Lebanon range it is copious. There is very little rainfall east of Damascus and over eastern Syria. Between the Orontes and Euphrates some of the slight rainfall is caught and stored up for the water supply. The water of the springs in the vicinity of Mount Lebanon is conducted into cisterns and conserved for domestic and agricultural purposes. Hundreds of water-wheels, operated by the current of the Orontes, or by animal power lift its waters to supply communities along its banks and to irrigate agricultural districts. Astride the Orontes 120 miles north of Damascus is the land of Hamath, supplied by six or more great under-shot water-wheels, some 80 feet in diameter,

that raise the water of the river into conduits extending through the city. Other sections are supplied with water drawn from wells by endless ropes carrying buckets and operated by camels turning vertical spindles. Irrigation in its primitive form is practised in parts of Syria. The Romans also practised it about the Sea of Tiberias, where the remains of aqueducts may still be seen. The waters of the Abana rushing down over wheels placed in the falls of the Anti-Lebanon ranges develop power to propel the street cars of Damascus and to light that ancient city, which obtains its water supply through conduits from the same sources. In Asia Minor swept by the cool winds of the Black Sea there is much snow and there are occasional heavy rains. It has many springs fed by the underground flow produced by the melting snows of its high mountains. It has some lakes, whose waters are somewhat depleted during the long dry season. In 1912, Dutch engineers designed and French contractors constructed irrigation works to utilize the waters of Bey-Sjehir and Jaila lakes and a canal connecting with the Tsartpajamba River to irrigate 126,000 acres of Konia Plain.

Over the territory extending from the Jordan to the Persian Gulf there is slight rainfall and much of it is a desert uninhabited.

In Siberia there is much snow and little rainfall. The latter ranges from 8 inches from Persia to Tobolsk and increases to 12 inches over Amur watersheds. Snow falls over vast areas in great quantities and in the mountains remains most of the year, feeding its lengthy rivers and its numberless lakes. Some of these, such as Baikal 400 miles long by 20 to 50 miles wide and Lake Kossogol 120 miles long by 50 miles, cover great areas in a basin that was once a much longer lake. In eastern Siberia rainfall averages from 15 to 20 inches. In Manchuria and northern China between the Volga and the Lena the rainfall ranges from 19 to 29 inches.

In China it ranges from 23 inches at Peking to 78 inches at Canton, which is swept by monsoons. It is only 5 to 7 inches in the north of Mongolia. In some coastal regions it amounts to 100 inches. Over the coastal regions of the Malay Peninsula the rainfall ranges from 75 to 200 inches and over places in Java it is 78 inches, at Singapore it is 97 inches. Siam is occasionally swept by monsoons and the rainfall ranges from 180 inches at Mergni to 240 inches at Monlmein. At some other places it averages from 42 to 54 inches.

In India there is the greatest variation in precipitation in Asia. In its western coastal and Himalaya regions rainfall ranges from 75 to 100 inches on the west to 250 inches at elevated localities, also in the west up to 610 inches in the Khasi Hills, where for a decade it averaged 550 inches. If entirely caught and conserved it would form a column of water 45 feet high. At Cherrapunji for 40 years it averaged 426 inches. At Calcutta it averaged 65 inches. At Ceylon from 60 to 80 inches. At Madras 55 inches. At Bombay 75 inches and in the valley of the Ganges it falls to 25 inches and in that of the Indus to 6 inches. At Poovah it is 24 inches. North of Punjab, it ranges from 70 to 80 inches and also that amount on some of the lateral spurs of the Himalayas.

There are no available records of precipitation in countries to the north of India, but they are light, cold and covered with snows, which are their principal source of water supply. In Burma on the west coast it averages from 157 to 196 inches. Over the Irrawadi Valley in Burma it is only 39.27 inches, but in the delta it averages 98.42 inches. In Japan the average rainfall over the whole country is 61.8 inches.

Australasia and Oceanica.—In Australia rainfall varies greatly in different sections. At Brisbane it averages 50 inches, at other places 70 inches. At Melbourne it averages 25.6 inches, at Port Phillip from 20 to 30 inches, at Adelaide 20 inches and in some parts of the Eyre Peninsula only 10 inches and this average extends to more than $\frac{1}{3}$ of the continent. In South Australia it averages from 8 to 10 inches. In 1889 the Department of Mines at Sydney collated rainfall data and estimated the amount at 50 or more watering places in Australia. Those showed the weekly rainfall to range from $\frac{1}{16}$ of an inch in some localities to an inch in others and still others it ranged from 2.25 to 3.10 inches. In most of the inhabited regions of New Zealand, rainfall ranges from 30 to 50 inches per annum. In New South Wales it ranges from 12 to 46 inches. At Hay it ranges from 10.94 to 25.84 inches.

In the Philippines there is great variation in rainfall. At Manila it averages 76 inches and ranges from 16.2 to 152 inches over different islands. At Kauai, one of the Hawaiian islands, it averaged for 4 years 518 inches. On the island of Mauritius rainfall on the east coast has been as high as 141 inches and on the west coast at the same time it averaged only 27.95 inches.

In Java a rainfall ranges from 70 inches at Batavia to 174 inches at Buitenzorg.

Except as otherwise stated, the foregoing are approximately the mean annual precipitation over the localities mentioned, as nearly as the measurements extending in most cases over a period of years disclosed. They furnish some data that may be considered in estimating such sources of their water supply.

Robert Lauterberg, meteorologist of Switzerland, once suggested that most measurements fail to give all the rainfall and that ordinary measurements must be increased 25 per cent to arrive at the actual precipitation.

There are, however, many instances of well-known departures from the amounts heretofore given, when in wet years or cycles of years, or localities of excessive precipitation, the maximum precipitation is greater than the mean annual precipitation. There are also dry years or cycles of years and dry localities, when the minimum precipitation is less than the mean annual precipitation. Such extremes are not constant, but may be considered in determining the hydrology of a given locality.

The foregoing records and measurements of rainfall are the mean annual precipitation over periods of years. Excessive precipitation, however, occurs in storms, when the hourly and daily rates in the localities affected may be extraordinary. Such storms are usually of short duration and are confined to small areas. Records of some of such excessive precipitations and of monthly tabulations in localities, where meteorological stations are maintained, are ob-

tainable from the reports of the weather bureaus of this and other countries. Most of such measurements are included in the general averages of mean annual rainfall hereinbefore stated.

Disposition of Precipitation.—The disposition of rainfall or precipitation is quite fully considered in the article on "Water Supply," which is to follow under that title in a succeeding volume of this encyclopedia.

HENRY W. HILL,
President of the New York State Waterways Association; author of 'Waterways and Canal Construction in the State of New York,' etc.

RAINIER, rá'nér', Mount. An old volcanic cone in central western Washington named from Admiral Rainier of the British navy by Vancouver the navigator, who saw it from Puget Sound in 1793. It is also known by the Indian name of Tacoma Peak and rises about 56 miles southwest of the city of Tacoma. Its altitude is 14,408 feet or about 8,000 feet higher than the adjoining Cascade Mountain region. It was once thought to be the highest peak in the United States but Mount Whitney in California is 93 feet higher and a few peaks in the Rocky Mountains in Colorado exceed it slightly. Its upper part is mostly covered by snow and ice, the latter in 11 main glaciers radiating from the summit like the arms of a great starfish. The glaciers are from four to six miles long and equal in size and beauty those in the Alps. The larger one extends down to 4,000 feet. A luxuriant forest extends part way up the slopes, and the timber line is between 7,000 and 7,500 feet. Around the base are many natural meadows of most picturesque character with profusion of summer flowers. The peak, "the noblest of the fire-mountains which, like beacons, once blazed along the Pacific Coast," is the remains of a huge volcano built up of thick layers of lava and originally 2,000 feet or more higher, its top having been blown off by a great explosion a few centuries ago. A large crater resulted from this eruption and several small cones and craters have since been built. The latest eruptions were slight ones in 1843, 1854, 1858 and 1870. Now the only activity is a slight emission of steam at one locality. The first ascent by a scientific observer was made by S. F. Emmons in 1870.

In 1897 it was ascended and thoroughly explored by a large party. "Almost 250 feet higher than Mount Shasta, its nearest rival in grandeur and in mass," they described it as "overwhelmingly impressive both by the vastness of its snow-capped summit, its glacial mantle and by the striking sculpture of its cliffs." The total area of its glaciers amounts to 45 square miles, an expanse of ice far exceeding that of any other single peak in the United States. The region now forms the fully protected Mount Rainier National Park created by act of Congress approved 2 March 1899. Centred by the towering mass of Mount Rainier, the park reserve is nearly a perfect square, the sides of which are 18 miles in length and contains 324 square miles, or sections of 640 acres each (207,360 acres). It is completely surrounded by lands embraced within the Rainier National Forest. Every year large numbers of tourists visit the park to camp in its meadows, and occasional ascents are made to the summit

of the mountain. Consult 'Mount Rainier National Park,' and *Annual Report* by the supervisor of the Mount Rainier National Park (Washington, D. C., Department of the Interior, 1915 et seq.).

RAINS, George Washington, American military officer and scientist: b. Craven County, N. C., 1817; d. Newburgh, N. Y., 21 March 1898. He was graduated from West Point in 1842, served in the engineering corps, was transferred to the artillery, and in 1844-46 was assistant professor of chemistry, mineralogy and geology at West Point. He served on the staffs of Generals Scott and Pillow in the Mexican War, and received brevet rank of major, was active in the Seminole War, and in 1856 he resigned from the army and engaged in business. At the outbreak of the Civil War he entered the Confederate service, was commissioned a colonel and placed in charge of the building and equipment of a powder mill at Augusta, Ga., where he remained until the end of the war, receiving promotion to the rank of brigadier-general. In 1867 he became professor of chemistry and pharmacy in the University of Georgia, and was dean of the faculty there till 1884. He was interested in mechanics, and secured several patents on his inventions for improvements for steam-engines. He wrote 'Steam Portable Engines' (1860); 'Rudimentary Course of Analytical and Applied Chemistry' (1872); 'History of the Confederate Powder Works' (1882), etc.

RAINSFORD, William Stephen, American Episcopal clergyman: b. Dublin, Ireland, 30 Oct. 1850. He was graduated from Saint John's College, Cambridge, in 1872, took orders in the English Church, and in 1873-76 was curate at Saint Giles', Norwich, England. In 1876 he came to the United States and engaged in evangelistic services in New York. He was assistant rector at Saint James Cathedral, Toronto, 1876-83, and in the last-named year became rector of Saint George's Church, New York, from which he resigned in 1906. Under his management the work of the parish was greatly extended and many societies and missions were established in connection with it. He became widely known as an earnest, fearless and eloquent preacher. He published 'Sermons Preached in Saint George's'; 'Reasonableness of Faith' (1902); 'A Preacher's Story of His Work' (1904); 'Reasonableness of the Religion of Jesus' (1913), etc.

RAINY LAKE, Canada, between Lakes Superior and Winnipeg, forms part of the boundary between Canada and the United States. It is very irregular in form, but about 55 miles in northeast by southwest dimensions, and mostly three to five miles wide. It receives the waters of numerous small lakes from the east and northeast, and empties itself by Rainy River, about 90 miles long, into the Lake of the Woods.

RAISED BEACHES. See **BEACHES**, **RAISED**.

RAISIN, the commercial name for the dried or cured grape. In Europe the raisin product comes largely from Italy and France, and in the United States almost wholly from California. See **RAISIN INDUSTRY**, **THE**.

RAISIN INDUSTRY, The American, is confined almost wholly to California. The raisin crop comes from the great San Joaquin Valley and from several counties in southern California. The California raisin grape culture began to be of commercial importance in 1874, when the output was 9,000 boxes, or 180,000 pounds of raisins. The industry advanced "by leaps and bounds" up to 1894, when the crop amounted to 103,000,000 pounds. The markets "broke" under this great output, and the crop sold for less than two cents per pound. As a result there was a sharp decline both in the acreage and in the output of raisins during the next four or five years. However, the growers protected themselves and their market by forming, in 1898, a Raisin Growers' Association, which controlled about 90 per cent of the yield. It had under contract in 1917, 155,000 acres of grapes. This association still continues to handle the bulk of the raisin crop, and has been quite successful in distributing to the best advantage the large output in the different markets. As a result the California raisin industry has had a phenomenal growth. It prospered because of the war since raisins are such a convenient and satisfactory fruit for shipping. Nearly all the raisins of the United States come from 11 counties of California, and 60 per cent of the product is from Fresno. The California product of raisins was: 1913, 130,000,000 pounds; 1914, 182,000,000 pounds; 1915, 256,000,000 pounds; 1916, 264,000,000 pounds.

Of the 1916 product 178,000,000 pounds were Muscats, and 47,000,000 Thompson's Seedless. Before 1896 the United States was a large importer of raisins. From 1887 to 1891 the average importation was 38,500,000 pounds; from 1892 to 1896 the average was 17,746,000 pounds; it is now negligible, and a large export trade is developing. In 1914 the exports were 14,766,000 pounds of the value of \$998,000; in 1915 the export was 24,895,000 pounds valued at \$1,719,000; and in 1916, 75,014 pounds, of the value of \$5,407,000. The raisins are packed and graded into layers, and one, two and three crown loose. The processes of curing, seeding and packing raisins have been improved from time to time, and to-day machines do much of the work formerly done by hand. The first great device was a patent seeder, and the latest one is a raisin-packing machine, by which the packages, or cartons, are filled, weighed and sealed.

The leading varieties of grapes used for raisins are the Muscat and Thompson's Seedless. Grapes are ripe by the middle of August, and the season often lasts into November. The average time of drying and curing a tray of raisins is about three weeks, all depending on the weather. The earliest picked grapes dry in 10 days, and the later ones often take four weeks and even more. The method of drying is very simple. The bunches are cut from the vines and placed on shallow trays two feet wide, three feet long, and one inch high, on which the grapes are allowed to sun-dry, being turned from time to time by simply placing an empty tray top side down on the full one, then turning both over, and taking off the top tray. After the raisins are dried they are stored away in the sweat boxes until they are packed and prepared for shipment. Some of the larger

growers, in order not to run so much risk in drying on account of rain, and also to enable them to handle the crop fast enough, have curing houses, where the curing is finished after having been partially done outside. The seedling, grading, packing and shipping have become separate branches.

RAISIN RIVER, Battle of. See FRENCH-TOWN, MICHIGAN, BATTLE OF.

RAJA, rā'jā, or **RAJAH**, a title of hereditary princes of the Hindus. The Hindustani form is rai, and it has also been rendered ras, rana and rawal. Before the subjugation of the country by the Moguls the various countries of Hindustan were governed by rajas, who belonged to the Kshatriyas or military caste. They were sometimes independent rulers and again feudatory, and the highest title, "Maharaja," was given to those who controlled other sovereigns. The title is now usually merely honorary and is not confined to any caste, while those retaining some degree of actual authority under the British are now designated "Maharaja." Consult Foy, 'Die königliche Gewalt nach den altindischen Rechtsbüchern' (1895); Jolly, 'Recht und Sitte' (1896).

RAJAMANDRY, rā-jā-mān'drē, or **RAJAMAHENDRI**, India, a town of the Godavari district, Madras, on the east bank of the Godavari (here three miles wide), 30 miles from the sea. Among buildings and institutions are the courthouse and judge's residence, churches, mission of the American Evangelical Lutheran Church, provincial college, several schools, museum, dispensary, public garden and large prison. Pop. 30,408.

RĀJATARANGINĪ, rā'jā-ta-rān'gē-nē (Sanskrit "Stream of Kings"), a Sanskrit chronicle of the kings of Kashmir, written by Kalhana about the middle of the 12th century. The history is written in eight cantos and has about 8,000 verses. It is remarkable as the only work in Sanskrit literature, yet discovered, with any historical value. The work makes use of earlier writings now lost and the first six books cover the period commencing with traditional history of early times down to the reign of Sangrama Deva, 1006; two later books, believed to be the work of Kalhana, bring the history down to the reign of Singha Deva, about 1156. The existence of the work first became known to Mohammedans in 1588, when during Akbar's invasion, a copy was given to the emperor. An edition was published in the Sanskrit text (Calcutta 1835); the text and translation by Troyer (Paris 1840, 1852); and there are translations by Datta (Calcutta 1898) and by Stein (Westminster 1900).

RAJMAHAL, rāj-mā-hāl', India, on the eminence overlooking the Ganges, 170 miles northwest of Calcutta, for many years capital of Bengal. It is now noteworthy only for its palatial ruins, and as a station in an important transit trade. The range of hills on which it stands bears the same name. These hills include a plateau with an area of 1,366 miles and support a population of hillmen or "Paharias," numbering about 75,000. The sides of the plateau are unusually steep and ascent is made largely by artificial stone steps. Consult Bradley-Bist, 'Story of an Indian Upland' (1905).

RAJON, rā-zhōn, Paul Adolphe, French etcher: b. Dijon C. 1842; d. Anvers, 8 June 1888. He was trained at the École des Beaux Arts at Paris, and in 1865 produced his first etching after Meissonnier 'Rembrandt at Work.' His many subsequent works won for him the leading position among French etchers, and on visiting England in 1872 he found his reputation had preceded him and was commissioned to make an etched copy of John Stuart Mill's portrait by George Frederick Watts and of Tennyson's portrait by the same painter. He was eminently successful in these and other portrait etchings, but his most ambitious and brilliant work was 'The Emperor Claudis' after Alma Tadema.

RAJPUTANA, rāj-poo-tā'na, India, a western political division, lying between 18 native controlled states and two chiefships. It consists of Sind and the Junjab; together with the British enclave of Ajmir-Merwara. The total area of the native states is 127,541 English square miles; or including the British district of Ajmir-Merwara, 130,462 square miles. The maharajas and rajas are supreme in their own states, and settle disputes among themselves in courts of their own. A great portion of the surface of Rajputana is desert, and part of it wholly destitute of inhabitants, water and vegetation. The whole of the soil is remarkably saline, containing many salt lakes, and much of the well-water is brackish. The rainfall is scanty, and the region frequently suffers from famine. In many places it is covered with the cactus and other prickly shrubs; except in the Aravalli Hills which traverse the region from southwest to northeast, the territory is almost destitute of trees. Where practicable, pastoral and agricultural pursuits occupy the people. Conditions have slightly improved since British enterprise has opened up the country by a transversal line of railroad, with diverging branches, connecting with the rest of the Peninsular Railway system. The chief town is Jaipur (Pop. 137,000); other urban centres are Bikanir, Jodhpur Bhartpur, Udaipur and Tonk. While the chiefs are of Rajput origin, the Rajput element is in the minority among the population, which consists chiefly of Hindus, with Mohammedans, Animists and Jains. Pop. 10,530,432.

RAJPUTS, rāj-poots', a people of India, giving their name to Rajputana (q.v.), and said to be a branch of the Kshatriyas, one of the four great castes into which the Hindus were originally divided. They are essentially a military people, and many of their institutions bear a strong resemblance to the feudal customs which prevailed in Europe in the Middle Ages. They are celebrated for their chivalrous spirit in marked contrast to the usual effeminacy and duplicity of many of the Oriental nations. The practice of female infanticide, however, at one time was prevalent among them, until suppressed by British influence; the profuse use of opium has likewise in many cases produced a lamentable deterioration in their physical and moral state. Notwithstanding these drawbacks the Rajput character contains much that is noble and generous. The Rajputs became first connected with the British government under the governorship of the Marquis of Wellesley, in the beginning of the 19th century. They num-

ber about 700,000. Besides Rajputana, the Rajputs are numerous in Sind and Guzerat.

RĀJSHĀHI, rāj-shā'hē, India, a division or commissionership of Bengal, extending from the Ganges to Sikkim and Bhutan. Area, 17,351 square miles; pop. about 8,489,788. The district of Rājshāhi, forming part of the division, has an area of 2,330 square miles; a population of about 1,400,000. The capital of the division and district is Rāmpur Beaulah.

RÁKÓCZY, rá'kót-sē, a Transylvanian princely family now extinct in the male line. They were for some time rulers of the principality of Siebenbürgen, or Transylvania, and by a rigorous maintenance of the civil and religious rights of the inhabitants made their influence over their subjects such as to render them formidable to the power of the royal house of Austria. The first prince of the name was SIGISMUND RÁKÓCZY, who obtained the government in 1606, but abdicated in favor of Gabriel Bathori in 1608. His son, GEORGE RÁKÓCZY (b. 1591; d. 24 Oct. 1648), assumed the sovereignty in 1629 and regained for his subjects many lost privileges. He was succeeded by his son GEORGE II (b. 1615; d. 8 July 1676), who attempted an invasion of Poland, was defeated and forced to abdicate, but regained his authority. He died after having been again forced to resign. His son, Francis I, never reigned, but was implicated in various political complications and the last of the family to hold sovereign power was his grandson, Francis II (q.v.).

RÁKÓCZY, Francis II, Transylvanian prince: b. 27 March 1676; d. Rodosto, Turkey, 8 April 1735. His attempts to free his country from Austrian rule resulted in his being sentenced to death for high treason, but he contrived to escape, rallied the Hungarians to his support and was proclaimed protector. The alliance of certain of the Hungarian states with Austria afterward caused his defeat and he resigned his estates and went to Turkey. He wrote '*Mémoires sur les révolutions de Hongrie*' (1738).

RÁKÓCZY MARCH, the name of a Hungarian military air by an unknown composer of the 17th century, said to have been the favorite march of Francis Rákóczy II of Transylvania. See NATIONAL HYMNS.

RALE, rāl (spelled also incorrectly, RASLE, RASLES, and RALLE), **Sebastien**, French Jesuit missionary in North America: b. Franche-Comté, 4 Jan. 1657; d. Norridgewock, Maine, 23 Aug. 1724. In 1675 he became a Jesuit novice at Dôle, in 1677-84 was an instructor at Carpentras and Nîmes, and in 1689 was sent to the Canadian missions. For two years he was among the Abenakis near the mouth of the Chaudière in the mission of Saint Francis. Then he passed two years among the Illinois, and finally was placed in charge of the Abenakis of Kennebec. He was believed by the English to be the cause of their difficulties with the Abenakis, and was accused of instigating attacks on the settlements and he was killed during an attack on the village of Norridgewock by New England militia assisted by Mohawks. This is inferred by pro-English historians from a letter to Rale from Vaudreuil, governor at Quebec, expressing satisfaction at Rale's success in uniting the savages against

the English, and agreeing to furnish military assistance, should it be required. This communication, dated 25 Sept. 1721, was among papers obtained by the expedition sent out from Boston under Colonel Westbrook to seize Rale in 1721, and is now preserved in the archives of Massachusetts. Among these papers, also, was Rale's dictionary of Abenaki, now in the Harvard library and printed in 1833, in the memoirs of the American Academy of Arts and Sciences. See DUMMER'S WAR.

RALEIGH, Sir Walter, English military and naval commander, and author: b. Hayes Barton, a farmstead in the parish of East Budleigh, Devonshire, about 1552; beheaded, London, 29 Oct. 1618. He was the son of Walter Raleigh by his third wife, Katharine, daughter of Sir Philip Champenowne of Modbury, and widow of Otho Gilbert of Compton. Raleigh was educated at Oriel College, Oxford; served with the Huguenot army in France in 1569; remained there for five years or more; and, with his half-brother, Sir Humphrey Gilbert, engaged in voyages of "discovery" — and piracy — against the Spaniards in the West Indies. In 1579 he established himself at court in the friendship of men of influence — Leicester, Oxford, Sidney, Walsingham; he served with distinction in Ireland (1580-81); and then, returning to court in December of the latter year, he won, and for some years retained, the high favor of Elizabeth. Through her successive grants of monopolies and estates he became one of the wealthiest of her courtiers. In 1584 he was knighted; in 1585 he was appointed warden of the stannaries (i.e., of the mines of Devon and Cornwall), lord lieutenant of the latter county and vice-admiral of both; and in 1585-86 he was M.P. for Devon. He was also captain of the queen's guard.

From this period, while Raleigh was the favorite of Elizabeth, dates his chief connection with the exploration and settlement of North America. In 1584, '85, '86, '87 and '89, he sent expeditions to Virginia; but as the Queen forbade his personal participation, his efforts to colonize were unsuccessful. Raleigh's services against the Spanish Armada, 1588, were not conspicuous. He assisted in organizing the land forces, but there is no proof that he took any part in the sea-fighting. In 1591 and 1592 he was prominent in the preparation of squadrons for service against Spain, but was recalled from the latter expedition because of the queen's anger at Raleigh's intrigue with one of her maids of honor, Elizabeth Throgmorton. He was soon set at liberty and his marriage to Elizabeth Throgmorton followed. Not until 1597, however, did Raleigh regain the queen's favor.

Meanwhile he was free to explore America in person. His objective point was Manoa, a city supposedly situated in South America and possessed of untold wealth. In 1595, with a fleet of five vessels, he captured the town of San Josef, Trinidad, and explored the Orinoco for 400 miles. He did not find Manoa; but his brilliant service in the English attack upon Cadiz (June 1596) and as commander at the taking of Fayal (1597) completed his restoration to favor. In 1597 he was made M.P. for Dorset; in 1601 for Cornwall. In 1600 he was appointed governor of Jersey.

SIR WALTER RALEIGH

The death of Elizabeth, however, occasioned a change in Raleigh's fortunes. Raleigh's enemies had made James believe that Raleigh was opposed to his accession. James immediately deprived him of all offices, and on 17 July 1603 committed him to the tower. On November 17 he was tried for treason. According to modern rules the evidence was insufficient, but Raleigh was declared guilty and was sentenced to be executed on 11 December.

On 10 December, however, he was reprieved and committed to the tower. Here for 13 years he lived in tolerable comfort with his wife, son and personal servants. He devoted himself to study and to scientific experiments, and, at the request of Prince Henry, began his chief literary work, the 'History of the World.' At length, in March 1616, on his promise to guide an expedition to a gold mine in America, Raleigh was released. The Spanish Ambassador, fearing an invasion of Spanish possessions or an attack on the Mexican plate-fleet, protested. The king, however, warning Raleigh that either act would be punishable by death, allowed him to proceed. Raleigh ignored the warning, captured San Tomás, and, failing to reach the mine, was kept from attacking the plate-fleet only by the refusal of his followers. On Raleigh's return to England, Gondomar, the Spanish Ambassador, demanded his immediate execution. Raleigh's admissions and perjuries left the king's commissioners no choice. On 28 October the justices of the King's Bench ordered Raleigh's execution under the suspended sentence of 1603. He was executed in the Old Palace Yard 29 Oct. 1618.

Of Raleigh's poetry, so highly praised by his contemporaries, but little was published during his life and much is probably lost. Many poems once attributed to him are now attributed to others. The poems, certainly his, have been collected by Dr. Hannah, 1885. Of Raleigh's prose works, the most important is his 'History of the World' (1614).

Bibliography.—The chief lives of Raleigh are those of William Oldys (1736); Thomas Birch (1751); Arthur Cayley (1805); Patrick Fraser-Tytler (1833); Edward Edwards (1868); J. A. St. John (1868); and Mr. William Stebbing (1891). That by Mr. Stebbing is the best. There is also a popular sketch by Mr. Edmund Gosse (1886). Consult also Mr. S. R. Gardiner's 'History of England,' and the publications of the Hist. MSS. Comm., and, concerning Raleigh's literary work, the introduction to Dr. Hannah's edition of his 'Poems' (1885), the bibliographies of Dr. Brushfield, and his 'Sir Walter Raleigh and His History of the World' (1887). Among more recent works are Selincourt's 'Great Raleigh' and biographies (1914) by Marshall and Towle.

ARTHUR H. NABON,
Instructor in English, New York University.

RALEIGH, Sir Walter, English author and educator. He was educated at University College, London, and King's College, Cambridge, and was for many years professor of modern literature at University College, Liverpool. In 1900 he was appointed to the chair of English language and literature at Glasgow University; and since 1904 has held the chair of English literature at Oxford University. He was knighted in 1911 and elected a Fellow of Mer-

ton College in 1914. He has published 'The English Novel' (1894); 'Robert Louis Stevenson' (1895); 'Style' (1897); 'Milton' (1900); 'Wordsworth' (1903); 'Shakespeare' (1907); 'The English Voyagers' (1904); 'Six Essays on Johnston' (1910); 'Romance' (1917).

RALEIGH, N. C., city, capital of the State, county-seat of Wake County, in lat. 35° 47' N., long. 78° 48' W., on the Southern, Norfolk-Southern and the Seaboard Air Line railroads, about 28 miles southeast of Durham, 148 miles northwest of Wilmington and 60 miles northeast of Pinehurst.

Topography.—Raleigh occupies an elevation of 363 feet. It is just northeast of the geographical centre of the State, in the upper valley of the Neuse River, which flows southeast to Pamlico Sound. The city, platted around a beautiful park of 10 acres, which is called Capitol Square, is divided into four sections by four broad streets which extend from this centre. The magnificent oak trees in Capitol Square give Raleigh the popular name of "The City of Oaks."

Manufacturing.—In 1900 the manufacturing interests of Raleigh represented an invested capital of \$1,611,000, with products valued at \$2,204,000. Cotton and fertilizer products are the leading articles of commerce. The largest manufacturing establishments are phosphate works, foundries, machine shops, car shops, wood-working factories, ice factories, cotton mills and cottonseed-oil mills. Other manufactures are underclothing, hosiery, carriages and agricultural implements. In 1914 capital invested amounted to \$2,012,000; products valued at \$2,916,000.

Buildings and Cemeteries.—The State Capitol, a substantial granite structure, stands in Capitol Square; nearby are the Supreme Court building, the State Library, State Geological Museum, Raney Library, Governor's mansion, United States government post office and courthouse. Other prominent public buildings are the county courthouse, State insane asylum, State penitentiary, State institutions for the blind, one for white and one for colored, State Institute for Deaf and Dumb, Old Ladies' Home and Rex Hospital. There are here National and Confederate cemeteries. The National Cemetery contains 1,207 graves, 572 of which are unknown dead.

Education.—The educational institutions are the Peace Institute (Presbyterian), Saint Mary's (Protestant Episcopal) and Meredith College for young women. The State College of Agriculture and Mechanic Arts, opened in 1889, has 26 buildings and accommodations for 800 students. Other schools are King's Business College; the Shaw University (Baptist) and Saint Augustine's School (Protestant Episcopal) are for colored boys and girls. Several State educational institutions have been mentioned. There are graded and normal schools for white and colored pupils. A large summer school for white teachers is held here each year. Not far distant from the city are the State University and the Wake Forest College (Baptist). The Supreme Court Library contains 21,375 volumes, the State Library 44,529 volumes and the Olivia Raney public library 14,121 volumes. All the religious denominations have handsome churches for both races. There

are two orphanages, one under the auspices of the Methodist Church, the other in charge of the Roman Catholic Church. There are two daily and 10 weekly newspapers.

Banks and Finances.—There are three national banks, one State bank and three savings banks. The banks have a combined capital of \$545,000 and deposits amounting to \$8,300,000. The assessed property valuation in 1915 was \$13,708,000. There are excellent fire and police departments, and all municipal improvements are provided for by a regular tax.

Government.—The city is governed under the commission charter of 1912, which provides for a mayor and two other commissioners elected every two years. The administrative officials are chosen by the mayor and commission.

History.—The site of the present city was selected in 1792 by the legislature for the location of the State capital. In the same year the city was founded and named in honor of Walter Raleigh (q.v.). In 1794 the legislature held its first session in Raleigh. The city was incorporated in 1795, and in 1803 was reincorporated. The city was occupied by General Sherman part of 1865. Pop. about 19,218. Consult Battle, 'The Early History of Raleigh.'

ALAN T. BOWLER,

*General Secretary, Chamber of Commerce,
Raleigh, N. C.*

RÂLES, sounds heard in the respiratory passages, due to certain modifications in the normal structure of the bronchi or alveoli, or both. Sounds that originate in the pleural cavity are distinguished as friction sounds. Râles are new sounds, not common to healthy lungs, and are created either in the bronchi, bronchioles, air-vesicles or pathological cavities. They are due to a number of causes, the most frequent of which are (1) the passage of air through narrowed bronchi, such narrowing being the result of inflammation of the mucous membrane or of muscular spasm, and (2) the passage of air through or by a certain amount of fluid, either mucus, pus, blood-serum or combinations of these. Râles of the first type are dry; those of the second are called wet. The dry râles are usually musical, and on placing the ear to the chest, where they are present, one hears either high-pitched whistling sounds, sibilant râles or low-pitched, blowing or sonorous râles, depending on the source of the sound, whether finer or larger bronchi. Both types may commingle. Such râles are common in asthma, in the chronic bronchitis of emphysema and in the early stages of a bronchitis, before the exudation of mucus has begun. The moist râles are usually of two kinds: (1) very fine or subcrepitant râles, resembling in sound the rubbing of a lock of hair between the fingers, and (2) larger mucous râles. The former are common in various types of disease in which the air-vesicles are involved, bronchopneumonia, lobar pneumonia, tuberculous pneumonia, etc. They are due to congestion and the pouring out of blood-serum into the area. The most mucous râles are present in bronchitis. They occur in the larger bronchi, or in cavities, and resemble the bubbling and gurgling sounds of water in a pipe. It requires the trained ear of the physician to distinguish between the

different varieties, and much experience to be able to prejudice the significance of the râles after they are heard.

RALPH, James, American author: b. Philadelphia, Pa., about 1698; d. Chiswick, Surrey, England, 24 Jan. 1762. He was a clerk to a Philadelphia conveyancer, and in 1724 went to England with Benjamin Franklin, who praises him as "ingenious" and "extremely eloquent." As an actor, editor and newspaper writer he was not successful. He then became a teacher in Berkshire, and was welcomed as an adherent of the Prince of Wales' party, which he supported by pamphlet, poem and newspaper contribution. Afterward bought into silence, he received a pension on the accession of George III. Pope ridicules "a thing of his, entitled 'Night,' a poem," in the lines of the 'Dunciad,'

"Silence ye wolvish while Ralph to Cynthia howls,
And makes night hideous — Answer him, ye Owls!"

Franklin pathetically complains that he "did his best to dissuade Ralph from attempting to become a poet"; but apparently Pope was more effective. Ralph's 'History of England during the Reigns of King William, Queen Anne and George I' (1744) is valuable for the information it contains.

RALPH, Julian, American author: b. New York, 27 May 1853; d. there, 20 Jan. 1903. At 13 he began newspaper work as typesetter and later engaged as reporter at Red Bank, N. J. From here he removed to Webster, Mass., to edit *The Times* of that place, and thence to New York, where he came into prominence in reporting the Beecher trial in 1875. He shortly engaged with the New York *Sun* and held a position on its staff for 20 years. He was in the East during the Chinese-Japanese War in 1894 reporting that struggle and traveling in many parts of Asia. Returning to London he joined the foreign staff of the New York *Journal* and reported the Turkish-Greek War, Queen Victoria's Diamond Jubilee in 1897, and the crowning of the Tsar of Russia. The outbreak of the Boer War found him again a field correspondent, attached to the commands of Lords Roberts and Methuen. He returned to America in 1902 and continued his work of special correspondent up to the time of his death. He had a wide knowledge of affairs and a picturesque and vivid style. Some of his books are 'On Canada's Frontier'; 'Our Great West'; 'Chicago and the World's Fair'; 'People We Pass'; 'Alone in China'; 'An Angel in the Web'; 'At Pretoria'; 'War's Brighter Side'; 'The Making of a Journalist.'

RALPH IRON. See SCHREINER, OLIVE.

RALPH ROISTER DOISTER, a play by Nicholas Udall. It was the first English comedy, although not printed until 1556, and probably written about 1540. At this time its author was head master of Eton, and the comedy was written for the schoolboys, whose custom it was to act a Latin play at the Christmas season. An English play was an innovation, but 'Ralph Roister Doister' was very successful. It follows Terence and Plautus. Ralph, "a swaggering simpleton, a feeble, conceited fop of the days of Henry VIII," having his prototype in the 'Miles Gloriosus.' It is in rhyming couplets, interspersed with songs.

In recent years it has been produced at Tufts College, Medford, Mass.

RALSTON, rāl'stŏn, William Ralston Shedden, English Russian scholar: b. London, 4 April 1828; d. there, 6 Aug. 1889. He was the son of W. P. Ralston Shedden and educated at Cambridge. During the period of his college years his father entered upon a litigation to obtain possession of some Ayrshire property and in this effort dissipated his whole fortune. The name of Shedden becoming somewhat notorious in connection with the suit, the son adopted the additional surname of Ralston; and obtained a post at the British Museum in 1853. He gave his attention to the study of Russian, a language then little known. He published 'Kriloff and His Fables' (1868), a translation of Turguénieff's 'Liza' (1869); 'Songs of the Russian People' (1872), and 'Russian Folk Tales' (1873). He made several journeys to Russia and became the life-long friend of Turguénieff, and was also made a corresponding member of the Imperial Academy of Sciences of Saint Petersburg. He projected an exhaustive history of Russia, but did not publish it. In 1874, however, he published his Oxford Taylorian lectures, 'Early Russian History.'

RAM, Thomas, English bishop: b. Windsor, 1564; d. Dublin, 24 Nov. 1634. He was educated at Eton and Cambridge, and in 1599 accompanied Essex to Ireland, and in the following year was made dean of Cork. On 2 May 1605 he was consecrated bishop of the united sees of Ferns and Leighlin. Ram was a careful bishop, constantly resident, and did what he could to maintain schools, but the recusant clergy excommunicated all who used them. He was one of the 12 bishops who, 26 Nov. 1626, signed a protest against tolerating popery.

RAM, Battering. See BATTERING-RAM.

RAM, Hydraulic. See HYDRAULICS.

RĀMA, rā'mā, in Hindu mythology the name common to a personage appearing as three incarnations of Vishnu (q.v.), all great warriors of surpassing beauty. These three forms are distinguished as Bala Rāmā or Balaram, Parasurama or Parasram, and Rāmā Chandra or Dasrat Rāmā. Rāmā first appeared in the sixth incarnation, and his deeds are celebrated in a poem called the 'Rāmāyana,' the best great epic poem of ancient India. In this poem all three of the heroes are celebrated, but the last-named, or Rāmā Chandra, has his life and deeds detailed at greater length than the others. The story tells how Sita, his wife, was carried away to Ceylon by the king of demons, one Ravana, and how Rāmā rescued his wife, bridging the water between Ceylon and India by the aid of an army of monkeys. He slew the demons and became a great hero. The Rāmāyana is often likened to the 'Iliad,' to which it bears great resemblance. See SANSKRIT LANGUAGE; SANSKRIT LITERATURE.

RAMADAN, rā-mā-dān', or rām-a-dān', the ninth month in the Mohammedan calendar, has 30 days. Since the Mohammedan year is a lunar one, Ramadan comes at all the seasons, being eleven days earlier each year. In about 33 years the month has made a complete cycle of the year. Ramadan is important chiefly because it is supposed to be the month in which Mohammed received his divine revelation and is there-

fore made a month of solemn observance among the faithful. During the 30 days the true believer abstains, between dawn and sunset, from all eating, drinking, smoking; bathing and all other delights of the body are likewise forbidden. The more devout of the Mohammedans remain behind closed blinds during the day and devote themselves to prayer and to reading the Koran, and particularly Sura, in the second book of which are found the references to the fast of Ramadan. There are special prayers, 20 in number, which during this month are added to the usual evening prayers, repeated at dusk by the true believer. Ramadan is also the month in which the Turkish government usually takes occasion to institute reforms, or to promise to institute them, apparently to curtail the national expenses and lighten the tax burden, and generally to undertake those measures that tend to popularize the government with its subjects.

The fast of Ramadan terminates each day with nightfall, and as the Mohammedan keeps the letter rather than the spirit of the law of the Koran, the nights of this month are filled with feasting, the more joyous because of the abstinence during the day. These repasts often become wild revels, or even flagrant debauches, which last until daylight, when the gluttoned participants once more betake themselves to fasting and prayer. Following the fast of Ramadan for three days there is celebrated the feast of the *Lesser Beiram*, during which all labor ceases and the Mohammedans give themselves to all sorts of table enjoyments. Consult Huart, C. I., 'Histoire des Arabes' (Paris 1912).

RAMALEY, rām'a-lī, Francis, American botanist: b. Saint Paul, Minn., 16 Nov. 1870. He was graduated at the University of Minnesota in 1895, and was assistant instructor in botany there in 1894-98. Since 1899 he has been professor of biology at the University of Colorado; and also director of the Mountain Laboratory, Tolland, Colo., since 1909. He has contributed articles on botany and public health to technical journals and is author of 'Wild Flowers and Trees of Colorado' (1909); 'Prevention and Control of Disease' (1913).

RAMAYĀNA, ra-mā'yā-na. Like almost all Hindū masterpieces the Ramayāna also is very lengthy. It has 24,000 distichs. It is well authenticated that Vālmiki, the poet, wrote the chief part of this epic; minor additions are by unknown authors. The theme treats of Rāma. It tells at great length of the abduction of Rāma's wife, Sitā, by an evil spirit, Rāvana, who took her to his cave, Lankā, in Ceylon, and whence Rāma, aided by the cunning ruler of the monkeys, Hanūman, finally carries her off into safety. At a much later date, and probably due to priestly inspiration, an addition is made to the poem in which Rāma becomes an incarnation of the god Vishnu. This simple tale is enormously elaborated and spun out to unreasonable and at times tedious lengths by various means, such as the injection of extraneous matter, fairy tales, anecdotes, animal fables, and so forth, until it acquired its present formidable length of nearly 50,000 lines, many of them of 11 syllables, others of 13 and 15. Parts of the Ramayāna indeed resemble in their mechanism quite closely that of the 'Arabian Nights,' one story leading to another,

often, too, independent tales being capsulated within others. It is quite evident, having due regard to the much greater antiquity of the Ramayāna when compared with the 'Arabian Nights,' that the latter drew largely on the first, both for manner and substance. As to the meaning of the chief part of the Ramayāna, it has been held by former scholars that it stands for a historical allegory, but now it is conceded by preponderance of opinion that it is merely an elaborated fragment of prehistoric Hindū mythology. It is more than likely that the main incidents and the kernel of the poem are of remoter origin than the oldest portions of the Mahābhārata. It is also quite within the bounds of possibility that Ramayāna, as well as Mahābhārata, first existed in oral versions, recited at great sacrificial feasts and similar gatherings, before being reduced to writing and assuming a settled form. This, too, would account most readily for the varying forms these poems assumed. Indeed, there is a Hindū tradition that Ramayāna was first chanted by Kuça and Lava, the sons of its principal hero. When making a comparison with Sakuntala, it would appear that Ramayāna is of distinctly inferior quality so far as poetical standards go. In Ramayāna there is frequently a tendency of 'piling Ossa on Pelion,' of great extravagance of diction. On the other hand, there is greater exuberance of fancy. The French translation of Ramayāna by A. Fauche (Paris 1863) is the best, and the summary by Monier Williams (London 1886) is also good.

Bibliography.—Dutt, R., 'The Epic of Rama, Prince of India' (London 1899); Hopkins, E. W., 'The Great Epic of India' (New York 1901); Jacobi, 'Das Rāmāyana' (Bonn 1893); Ludwig, 'Ueber das Rāmāyana und die Beziehungen desselben zum Mahabharata' (Prague 1894); Roussel, 'Le Ramayana' (3 vols., Paris 1903-09); Weber, 'Ueber das Rāmāyana' (Berlin 1870).

WOLF VON SCHIERBRAND.

RAMBAUD, rān-bō, Alfred Nicholas, French historian and litterateur: b. Besançon, 2 July 1842; d. 1905. He was educated at the Ecole Normale; in 1871 became professor of history at Caen and in 1875 was transferred to the same post at Nancy. In 1879 he became secretary to the ministry of public instruction, and in 1881 was nominated to a position in the normal school at Caen and shortly afterward made professor of modern history at Paris. From 1896 to 1898 he was Minister of Public Instruction in the Méline Cabinet. His chief works are 'La Russie Epique' (1876); 'Histoire de la Russie' (1878); 'Histoire de la Civilisation Française' (1887); 'Histoire de la Civilisation Contemporaine en France' (1888); in collaboration with M. Lavis, 'Histoire Generale de la France du IVe Siècle à nos Jours' (1892).

RAMBERG, rām'bērg, Arthur, BARON, German painter: b. Vienna, 4 Sept. 1819; d. Munich, 5 Feb. 1875. He studied art at Hanover and early made a tour in Italy, Hungary and Styria. In 1840 he attended the university at Prague, while at the same time uniting the pursuit of art with his other studies. In 1842 he became a pupil at the Art Academy of Dresden under J. Hübner, and among other early

pictures produced his 'Wedding of Dwarfs' after Goethe; and 'The Emperor Henry I on His Hungarian Campaign.' In 1850 he went to Munich and executed a series of genres illustrating the works of Schiller. In 1860 he was appointed professor to the Art School in Weimar, and six years later took a similar position in the Academy of Munich. His subsequent productions include 'The Court of Frederick II in Palermo'; and, among his genres, most notable are his 'Hermann und Dorothea' after Goethe; and 'Luise,' after the poem of J. H. Voss, which latter was much admired for its brilliancy in design and execution. He also frescoed the walls of Luther's chamber at Wartburg; and for the Grand Duchess of Saxe-Weimar illustrated the tale of the 'King of the Frogs.'

RAMBERG, rām'bērg, Johann Heinrich, German artist: b. Hanover, 1763; d. there, 6 July 1840. He first showed his talent by drawings of scenes in the Harz Mountains. These became known to George III, king of England, his sovereign, as Elector of Hanover, who induced him to go to London, where he provided for him. He remained there nine years, and perfected himself under Reynolds. In 1788 the king sent him to Italy, whence he returned to Hanover where he was appointed painter to the court. He distinguished himself particularly in humorous drawings; as in his illustrations to 'Reineke Fuchs' and 'Eulenspiegel.' The drawings in the magnificent edition of Wieland's works are all by him; some he etched himself.

RAMBLER, The. Though no longer read with the enthusiastic admiration formerly accorded it, Johnson's 'Rambler' has at least retained the respect of the thoughtful student of the history of English literature. The essays were distinctly of their day and, like all Johnson's writings, distinctly of their author. They followed the fashion of the periodical literature established by Addison and Steele in ranging over as wide a field of social and moral conduct as the fancy or ingenuity of the author led him. Temperamentally Johnson was not so well fitted to write the familiar essay as he was for more serious discourse. 'The Rambler' consequently suffers in comparison with the essays of Addison and Steele. A certain dramatic element in characterization appears in 'The Spectator' which is very little present in 'The Rambler.' Johnson created no such personages as Sir Roger de Coverley or Beau Tibbs. The essays are lacking also in variety. One 'Rambler' seems very much like another, and though it is scarcely a fair test of them to sit down and read them as a volume, since they appeared periodically and were intended to be read one at a time at intervals, this disadvantage is one that must be faced by all literature of a journalistic character. One may at least expect that certain portions of such writing shall stand out with sufficient significance to carry the rest along with it. Then again Johnson's didacticism is presented with a simple directness that seems to have been enjoyed in an age when men suffered moral instruction more patiently than they do to-day. Johnson never sought for ingenious cases of conscience to form the foundation upon which his reflections were based. His didacticism re-

minds one of the obvious teaching of the sermon, a characteristic which led some one to propose, facetiously, the influence of Dr. Johnson's 'Rambler' upon the high school graduation essay, as a subject for scholarly research. With all these qualifications, however, there still remains enough in 'The Rambler' to justify the student in giving to it respectful and serious consideration. If the essays never rise to great heights of imagination, they are never cheap or trivial. Throughout they are characterized by good sense, often by genuinely elevated thought and feeling. Their evenness of tone, from one point of view tending to monotony, is also not without its virtue. The essays appeared twice a week over a period of two years, and in the end they present if not a systematic code of conduct, something which is perhaps a good deal better, the detailed picture of a mind conscious of itself and of its riches, and sure of the position it wants to take in any situation in which it may be placed. One may be inclined to criticise some of Dr. Johnson's literary ideals, but the mastery of technique with which they were put into effect calls for no apologies. Granted the aim and the method, Dr. Johnson's prose is among the best in the English language, and 'The Rambler' will repay the careful study of any one who wishes to see how a serious mind realizes itself in appropriate and effective expression.

GEORGE PHILIP KRAPP,

Professor of English, Columbia University.

RAMBOOTAN, the fruit of the tree *Nephelium lappaceum*, of the family *Sapindaceae*, much prized in the Malayan Archipelago. It is about the size of a pigeon's egg, of a red color, rich and of a pleasant acid taste. The fruits litchi and logan (see **LITCHI**) are obtained from other trees of this genus.

RAMBOUILLET, *rān-boo-yā*, Catherine (DE VIVONNE), MARQUISE DE, French social leader: b. Rome, 1588; d. Paris, 2 Dec. 1665. She is worthy of remark as the founder of the Hôtel de Rambouillet, whose hospitality was extended to the learning and wit of Paris; and which became a literary and political centre. This salon was developed in opposition to the French court circle, whose vulgar and barbarous manners and speech it strove to offset by elegance and refinement in both, and it soon became the rendezvous of celebrity and wit. Among the critics, poets and scholars who resorted thither were Malherbe, Corneille, Chaplain, Scarron, Saint-Evremond, La Rochefoucauld, Mme. de Sévigné. Henry IV and Louis XIII were quite indifferent to letters, and in default of royal patronage the Hôtel assumed the rôle of arbiter in matters literary. Imitators perverted the original characteristics of the group into pedantry and affectation and occasioned the historic satires of the great Molière in 'Les Précieuses Ridicules' and 'Les Femmes Savantes.' The Hôtel did much to add to the precision and finish of the language and the establishment of good taste; and it was unfortunate that through the playwright its name took on the nature of a derisive epithet. Consult Röderer, 'Mémoire pour servir à l'Histoire de la Société Polie en France pendant le Dix-septième Siècle' (1834); Brunetière, 'Nouvelles Etudes Critiques' (2d ed., 1886); Vincent, 'The Hôtel de Rambouillet' (1900).

RAMBOUILLET, a breed of sheep (q.v.).

RAMEAU, *rā-mô*, Jean Phillippe, French musical composer and theorist: b. Dijon, 25 Sept. 1683; d. Paris, 12 Sept. 1764. Having early acquired some skill in music he joined a company of performers, by whom when he was 18 a composition of his was represented at Avignon. He studied sacred music under Marchand at Paris; was appointed organist in Clermont Cathedral, and in 1722 made his reputation as a musical theorist by publishing 'Traité de l'Harmonie.' Four years after appeared his 'Nouveau Système de Musique Théorique,' which was followed by his 'Génération Harmonique.' His greatest claim to musical reputation is based upon his dramatic compositions, of which 'Hippolyte et Aricie' appeared in 1732 and was followed by 22 works of grand opera, of which the most notable is 'Castor and Pollux' (1737). In 1750 he published his 'Dissertation sur le Principe de l'Harmonie,' in which he reduces harmony to one single principle—the fundamental bass, on which he proves all the rest to depend. This work procured him an invitation from the court to superintend the opera at Paris. Louis XV granted him a patent of nobility, and the order of Saint Michael, and in 1876 a statue was raised to him in his native city. Consult Pougin, 'Rameau, Essai sur sa Vie et ses Œuvres' (1876).

RAMÉE, *rā-mā'*, Louise de la. See OUIDA.

RAMÉE, Pierre, *pē-ār rā-mā* (Latinized, PETRUS RAMUS), French humanist and mathematician: b. Cuth, near Soissons, 1515; d. Paris, 26 Aug. 1572. He went to Paris when he was but eight years old, and became lackey to a rich student in the College of Navarre, but devoted to self-improvement all the time he could spare. After attending a course of philosophy he was admitted to the degree of M.A., on which occasion he questioned the infallibility of Aristotle. His 'Institutionum Dialecticarum Libri III' (1543), and 'Animadversionum in Dialecticam Aristotelis Libri XX' raised a storm against him in the university; their publication was prohibited, and extant copies ordered to be burned before the Royal College of Cambria. Having obtained the patronage of the Cardinal De Lorraine, the prohibition of lecturing imposed in 1543 was withdrawn in 1547, and in 1551 he was appointed professor of rhetoric and philosophy in the College Royal at Paris. His spirit of free inquiry ultimately led him to become a Protestant, and he was obliged to flee from Paris, but he unfortunately returned in 1571 and was killed in the massacre of Saint Bartholomew. His works, relating to grammar, logic, mathematics, etc., are numerous. His doctrines were widely diffused. France, England and particularly Scotland, were full of Ramists. His logic was introduced into the University of Glasgow and in the German universities. Consult Waddington, 'Ramus, sa Vie, see Ecrits et ses Opinions' (1855); Desmazes, 'Ramus' (1864); Lobstein, 'P. Remus als Theolog' (1878); Voigt, 'Ueber den Ramismus der Universität Leipzig' (1888); Owen, 'Skeptics of the French Revolution' (1893).

RAMENGHI, rā-měng'gē, Bartolomeo. See BAGNACAVALLLO.

RAMESES, rām'ē-sēz, or **RAMSES** (in Egyptian "the Child of the Sun"), the name of several Egyptian kings, especially of the 19th and 20th dynasties, of which the most notable are:

RAMESES II (Gr. *Sesostris*), son of Sethos. He was the third king of the 19th dynasty, and reigned 1300-1280 B.C. He made a campaign against Syria and advanced victoriously as far as Berytus (Beirut), on the Phœnician coast of the Mediterranean. He next extended Egyptian dominion over Ethiopia and a part of Arabia and began the cutting of a canal between the Mediterranean and Red seas. But the great event of his reign was his war with the Khita, supposed to be the Hittites. He defeated a confederation, among whom the Khita were the chief, in a great battle near the Kadeshon (Orontes) in Syria, and subsequently took Jerusalem and other places. He fortified the east of Egypt by erecting a great wall from Pelusium to Heliopolis and Tanis. In his reign Thebes rose to great magnificence. Here he erected the splendid temple known as the Rameseum, with a sitting statue of himself more than 60 feet high. The figure of Rameses II at Tanis, parts of which were discovered, was 92 feet high, or with its pedestal 125 feet. It was erect, with the left foot advanced, and probably the tallest of ancient statues. He is the king who oppressed the Hebrews, and the father of Menephtah, under whom the exodus took place. He had 111 sons and 59 daughters, and we have more records and statues of him than of any other Pharaoh. His mummy was discovered near Thebes in 1881 and in 1886 placed in the Egyptian Museum at Cairo.

RAMESES III, the Rhampsinitus of Herodotus, belonged to the 20th dynasty, and was also a king of note, some of whose achievements seem to have been ascribed to Sesostris. He reigned 1180-1150 B.C., during which period he had to withstand many invasions of the surrounding nations, but was uniformly successful in war, and active in great undertakings in time of peace. At Medinet-Abu he built a magnificent temple in memory of his warlike achievements in Nubia and Syria. The mummy of Rameses III was found in 1886. Nine other kings of the name of Rameses are mentioned as having belonged to the 20th dynasty (1150-1050).

RAMESES, a city of Egypt, in the district of the same name, supposed to be the same as Raamses, one of the treasure-cities built for Pharaoh by the children of Israel during their bondage in Egypt. It was from this point that the Israelites set out in their exodus from Egypt; and its geographical position is therefore of great interest as determining their route toward the Red Sea. The district or "land" of Rameses has been identified by some with Goshen, or a part of Goshen. As for the city, some have supposed it to be in the neighborhood of On or Heliopolis; others somewhere near Old Cairo, on the opposite side of the Nile from ancient Memphis; Dr. Robinson placed it in the valley of Wady Toumilât, toward the east end of that valley, in the line of the fresh-water canal to Ismailia; and Dr. Lepsius thought he had found its site at Tell-el-Maskhuta, in that

region. This site, however, has been identified by Naville with Pithom. It is argued in favor of the conjecture which places it in the neighborhood of Memphis, that Rameses must have been near the capital or residence of Pharaoh at the time of the exodus, and as this was Memphis, Rameses must therefore have been near this city. But though Memphis was the ancient capital, it does not follow that the Egyptian king invariably resided there. Tanis or Zoan was also a royal residence, and Brugsch identifies Rameses with it, an identification which suits the biblical narrative quite well. Upon the name of the city is based the theory which identifies Rameses II with the Pharaoh of the oppression.

RAMESSEUM, rām-ēs-sē'ūm, a temple of ancient Egypt, on the western bank of the Nile, situated opposite Thebes, and near the modern village of El-Kurneh. Its ruins constitute one of the most interesting groups of ancient Egyptian remains, owing to the rich mural sculptures of great historical value which are there preserved. The principal features of the temple were two great courts about 140 feet long by 180 feet wide, entered through a propylon 225 feet wide. The front court contains the fragments of a gigantic statue of Rameses II carved from a single block of granite and estimated to have weighed, when entire, more than 850 tons. The statue was 60 feet high and the monarch was represented as seated on his throne. The columns in both courts are among the most beautiful specimens of Egyptian architecture. On the wall of the second court is a great series of sculptures depicting a battle between Rameses II and the Hittites, in which the king is shown as victoriously pursuing the enemy's forces. Opening on the second court is a beautiful hall of pillars, the walls of which are adorned with battle scenes and religious subjects. A smaller chamber adjacent to the hall of pillars is notable for its astronomical ceiling. The temple was described by Diodorus Siculus under the name of the Tomb of Osymandyas. It is sometimes called the Memnonium.

RAMESWARAM, rā-mēs'wā-rām, or **RAMESHWARAM**, a low sandy island between the southern extremity of India and Ceylon, and between the Gulf of Manaar and Palk Strait, about 14 miles long and five wide. It is one of the islands that form the chain known as Adam's Bridge, and contains a famous Hindu temple of Dravidian architecture, which attracts many pilgrims from all parts of India. The port of the island is Pambam; it also contains a small town called Rameswaram. There is a passage for ships of moderate size between this island and the continent. Pop. 17,854.

RAMIE, **RHEA**, or **CHINA GRASS**, *Bahmeria tenacissima* and *B. nivea*. Shrubs, five to eight feet high, producing in the bark of their stalks or stems a bast fibre. Technically ramie and rhea are derived from *tenacissima* and China grass from *nivea*. This distinction has never been regarded, however, in the economic literature of the subject, the term ramie being commonly used to designate all *Bahmeria* fibre, China grass being either a synonym or the trade name of the Chinese fibre as imported. In the statements which follow, therefore, ramie and China grass may be considered as synonymous terms, referring to

the fibres of both species, as they are practically identical from the standpoint of commercial utility, and as regards culture, preparation and manufacture.

The fibre is strong and durable, is least affected by moisture of all fibres and takes first rank as a textile substance. It is adapted to the widest range of uses of any known textile. It has been made into stuff goods for men's wear, ladies' dress goods, upholstery, curtains, laces and embroideries. The pile of velvets and plushes, stockings, underclothing and knit goods, table damask, napkins, handkerchiefs, shirtings, sheetings, sail duck, carpets, cordage, fishing nets and yarns and threads of all descriptions, and it makes a superior bank-note paper. It is also used to adulterate silk and for imitation silk goods. The plant has been the subject of experiment in nearly every country in the world, and probably millions of dollars have been spent or wasted, in attempts to exploit the industry, or in the construction of machines to extract the fibre. Yet the fact remains that the commercial fibre is produced only in China and by rudest hand methods, Japan coming the nearest to establishing a commercial industry for the production of export fibre. Ramié is neither grown nor to any extent manufactured in the United States, though its culture was experimented with for years, and inventors and textile manufacturers have struggled with the machine problem and with the after preparation and the spinning of the fibre. As far as this country is concerned the fact that the Chinese fibre can be laid down in San Francisco for about four cents a pound condenses the entire ramié situation into a nutshell. Cultivation in this country would not pay at such prices, and there is not a machine in existence that could produce enough marketable fibre in a day to pay for the cost of running the machines when American wages are considered.

Ramié manufactures have been on the market for years, derived from European sources, and made from raw fibre produced in China. And many manufactures made in whole, or part, from ramié are sold as something else, because the fibre is unknown to the public, or because it is used as an adulterant, as in silk fabrics. See CHINA; CORDAGE; FIBRE; HEMP.

Consult 'Report on Rhea Fibers (Watson 1875); Bulletin Royal Kew Gardens; Dictionary Economic Products of India; Reports (1, 2 and 7) Office of Fibre Investigations, Department of Agriculture; also the French publications of Favier, De Landtsheer, Michatte, Roux, Ringlemann, and the ramié literature published by the Ministry of Agriculture of France.

CHAS. RICHARD DODGE.

RAMILLIES, rā-mē-yē, a village of Belgium, in the province of Brabant, 13 miles north of Namur and 28 miles southeast of Brussels. On 23 May 1706 the Duke of Marlborough gained here a signal victory over the French under Marshal Villeroi and the Elector of Bavaria. The numbers were about 60,000 on each side; the loss of the allies was about 4,000 men, that of the French 15,000. The consequence of this battle was the immediate evacuation by the French of the chief strongholds in the Netherlands. It was again the scene of

severe fighting in 1914. See SUCCESSION WARS; WAR, EUROPEAN.

RAMMAN, rām'man, or **RIMMON**, a deity worshipped by the Babylonians and sometimes called also Hadad. He was the god of the all-pervading atmosphere, especially of the winds. In this respect he may be likened to the Meeruts, or storm gods of northern India, for his name is derived from a Babylonian word meaning "loud sounding" or "bellowing." In the Bible "the House of Rimmon" is spoken of as his temple at Damascus (2 Kings v, 18). He is symbolized by the bull; is the god of storms and floods and of the charge of battle and is represented armed with thunderbolt and battle-axe. Consult Baethgen, 'Beiträge zur semitischen Religionsgeschichte' (1902); Jastrow, 'Religion of Babylonia and Assyria' (1898).

RAMMOHUN ROY, rām-mō-hūn' roi, Hindu religious reformer: b. Burdwan district, province of Bengal, India, 1772; d. Stapleton Park, near Bristol, England, 27 Sept. 1833. He was a Brahman of strict education, but early renounced the polytheism of Brahminic theology. For five years he was dewan, or principal native officer in the collection of the revenues, in one of the districts of East India Company's services. He afterward studied Latin, Greek and Hebrew. A careful study of the sacred writings of the Hindus had convinced him that the prevailing religious notions of the Hindus were grounded upon a gross perversion of their religion, the original records of which appeared to him to inculcate a system of pure theism. He now became anxious to reform the creed and practice of his countrymen, and determined to devote his talents and his fortune to this undertaking. A work of his in Persian on 'The Idolatry of All Religions' aroused much protest. In 1814 he went to live in Calcutta, where as early as 1818 he had united a number of intelligent Hindus in a species of monotheistic worship. He translated the Vedānta, a compendium of the doctrines contained in the Vedas or ancient sacred books of the Hindus, from the Sanskrit into the Bengali and Hindustani languages, and distributed the translation gratuitously. This he afterward published in English, for the purpose of proving to his European friends "that the superstitious practices which deform the Hindu religion not having to do with the pure spirit of its dictates." From the perusal of the New Testament he found (he says) the doctrines of Christ more conducive to moral principles, and better adapted for the use of rational beings, than any other which had come to his knowledge. In 1820 he accordingly published the 'Precepts of Jesus the Guide to Peace and Happiness,' consisting chiefly of a selection of moral precepts from the Evangelists, and Unitarian in its character. On 23 Jan. 1830 he founded at Calcutta the Brahmīya Somaj, from which was derived the Brahmo Somaj.

Rammohun Roy, in his doctrinal views, was a Unitarian, holding, however, the pre-existence and superangelic dignity of Christ, and considering the doctrine of the Trinity as a species of polytheism. He believed possible a combination of Brahminism and Christianity. His views were at first much misunderstood in

England, and it appears that even Bishop Heber regarded him as an atheist. In 1830 he went to England in the character of ambassador from the king of Delhi (who gave him the title of Rajah). Consult Carpenter, 'A Review of the Labors, Opinions and Character of Rajah Rammohun Roy' (1833); Fox, 'Discourse on Occasion of the Death of Rajah Rammohun Roy' (1833); Max Müller, 'Biographical Essays' (1883).

RAMONA. 'Ramona' (1884), by Helen Hunt Jackson, was written to carry forward an indictment already begun in the author's 'Century of Dishonor' (1881) against the treatment of the Indians by their white conquerors. 'Uncle Tom's Cabin' comes at once to mind, but the two books have little in common besides an analogous intention. Mrs. Jackson romantically eluded the problem by making Ramona, the heroine, and her Temecula husband, Alessandro, so near to high-caste Mexicans in color and nurture that their wrongs as Indians seem untypical of the real grievances of their unfortunate race. They suffer little more from the invading Yankees than do the full-blooded Mexicans. Indeed, the true conflict and injustice occur between the old Californians, Indian or Spanish, and the predacious vanguard of the Anglo-Saxon conquest. California, for Mrs. Jackson, was a splendid paradise of patriarchal estates in vast fertile valleys, steeped in a drowsy antiquity, and cherished by priests as unworldly as Saint Francis. Against this rich background she set a story which begins in peace, blackens to hard and ugly tragedy and then grows at the end into peace again. The pomp of the setting, the strength of the contrasts, the eloquence, the intensity, the passionate color dominate, almost submerge, the problem stated, but they tend also to lift it into the higher regions of the imagination in which particular acts of injustice take on the large significance of universality.

CARL VAN DOREN.

RAMPION, a biennial herb (*Campanula rapunculus*) of the family *Campanulaceae*. It grows about 30 inches tall, has a parsnip-like root, obovate leaves, lilac flowers in a spike or raceme, and very small seeds. It is a native of Asia, Europe and northern Africa, where it is cultivated for its roots and leaves, the former of which are used like radishes, the latter like spinach. The plants do best in light, rich loam, partially shaded and well supplied with moisture but not wet. Since early spring sown plants are likely to run to seed, other sowings should be made in early summer. The plant is less popular in America than abroad.

RAMPOLLA, rām-pōl'lä, Mariano, MARQUIS DEL TINDARO, Roman prelate: b. at Polizzi, Sicily, 17 Aug. 1843; d. 1913. Born of an aristocratic family he was educated at Rome and took priest's orders at 23. Several years later he entered diplomacy and was made secretary to the Papal nunciature at Madrid. During the absence of the Nuncio Simonei in 1876 he acted so brilliant a part during the Carlist war as to secure his appointment as secretary of the Congregation of the Propaganda. In 1885, being then Papal Nuncio at Madrid, he proposed

Pope Leo XIII as arbitrator in the dispute between Spain and Germany regarding the Caroline Islands. In 1887 he was created cardinal and made papal secretary of state, which post he held until the appointment of the new Pope Pius X in 1903. The foreign policy of the Vatican was influenced by him and consisted of a conciliatory attitude toward France together with an opposition to the Triple Alliance, with the ultimate end in view of re-establishing the temporal power of the Pope. Upon the death of Leo XIII, Cardinal Rampolla was one of the most prominent candidates to the succession. Austrian interests opposed him and when Pope Pius X was elected, Rampolla resigned as secretary, being succeeded by Cardinal Merry del Vall (q.v.).

RAMPUR, rām-poor', India, (1) capital of a state of the same name, on the left bank of the Kosila River, in Central India. It is the residence of the nawab, who represents the Rohilla chieftain of Rohilkhand. A lofty mosque is a specimen of oriental magnificence. The place is famous for its damask, sword-blades and jewelry. Pop. 78,758. (2) The state under the superintendence of the government of the United Provinces has an area of 893 square miles. Pop. 533,212. (3) A smaller Indian town, capital of Bashahr, in southeastern Kashmir, formerly famed for its shawl manufactures. Pop. 7,945.

RAMSAY, rām'zī, Allan, Scottish poet: b. Leadhills, Lanarkshire, 15 Oct. 1686; d. Edinburgh, 7 Jan. 1758. The death of his father in early life forced him to seek a means of livelihood in the Scottish capital. There he became bound as an apprentice to a wig-maker, which occupation he continued after his apprenticeship had ceased. The exact period when he commenced bookselling is unknown, but he is said to have been the first who established a circulating library in Scotland. The library continued to exist till a comparatively recent period. His first shop, as we learn from the imprint of some of his books, was "at the sign of the Mercury, opposite to Niddry's Wynd"; but in 1726 he removed to a house at the east end of the Luckenbooths and adopted for his sign the heads of Ben Jonson and Drummond of Hawthornden. In 1721 he published a collection of his poems which was so liberally subscribed for that he is said to have cleared by it 400 guineas. These poems had originally appeared on separate broadsheets and sold for a penny each. In 1724 the first volume of 'The Tea-Table Miscellany,' a collection of songs appeared, which was soon followed by two others. Shortly afterward he brought out 'The Evergreen, being a Collection of Scots Poems wrote by the Ingenious before 1600,' which was equally successful. In 1725 appeared his famous pastoral, 'The Gentle Shepherd.' Its success was instantaneous and edition followed edition with great rapidity. In 1728 a second quarto volume of his poems appeared; and his 'Thirty Fables,' undoubtedly the best of Ramsay's lesser productions. He was now at the height of his celebrity and his shop was the common resort of the literary characters and wits of Edinburgh. He spent the last 12 years of his life in a quaint house he had built on the north side of Castle Hill, although he did not give up his shop until within three years

of his death. He was buried in Greyfriars' Churchyard, where a monument has been erected. Another monument, erected in 1865, stands in Princes' Street Gardens. Consult 'Life' by Smeaton (1890); Graham, 'Scottish Men of Letters in the 18th Century' (1901).

RAMSAY, Allan, Scottish portrait painter, son of the preceding: b. Edinburgh, 1713; d. Dover, 10 Aug. 1784. He studied art in London and in Italy and by 1758 had achieved a high reputation. George III appointed him principal court painter. Walpole regarded some of his portraits of women superior to Reynolds'. He painted portraits of Gibbon, Chesterfield, Hume, Rousseau and many others, now in the National Portrait Gallery and the gallery at Edinburgh. The portrait of George III preserved at Independence Hall, Philadelphia, is his work.

RAMSAY, Sir Andrew Crombie, Scottish geologist: b. Glasgow, Scotland, 31 Jan. 1814; d. Anglesey, England, 9 Dec. 1891. In 1841 he joined the geological survey, with which he was connected until 1881. He became professor of geology at University College, London, in 1848; was lecturer at the School of Mines, 1851; president of the Geological Society, 1862, and director-general of the Geological Survey and the Museum of Practical Geology, 1872-81. He was popular as a lecturer and held the theory that many lake basins are the result of glacial excavations. As a geologist he devoted himself to stratigraphy to the exclusion of paleontology and petrography. His works include 'Old Glaciers of North Wales and Switzerland' (1860); 'The Physical Geology and Geography of Great Britain' (1872), etc.

RAMSAY, Andrew Michael (CHEVALIER RAMSAY), Scottish scholar: b. Ayr, Scotland, 9 June 1686; d. Saint Germain-en-Laye, France, 6 May 1743. He was educated at the universities of Edinburgh and Saint Andrews and being deeply interested in theological matters he went to Leyden where he formed a friendship with the mystic Poirret through whom he visited Fénelon, archbishop of Cambrai, in France, in 1710. The latter took a deep interest in Ramsay, succeeded in converting him to the Roman Catholic faith and kept him with him until his death in 1715, when he bequeathed to Ramsay his papers. Ramsay then became tutor to the Duc de Château-Thierry and subsequently acted in the same capacity to the sons of the Pretender, Francis Edward, at Rome. He visited England in 1730, was elected to the Royal Society and on his return to Paris became tutor to the Vicomte de Turenne. His writings were published in excellent French, but though of considerable merit and very popular in his day, are now rarely read. They include 'Essai Philosophique sur le Gouvernement Civil' (1721); 'Vie de Fénelon' (1723); 'Poems' (1728); 'L'Histoire du Vicomte de Turenne' (1735), etc.

RAMSAY, David, American physician and historian: b. Lancaster County, Pa., 2 April 1749; d. Charleston, S. C., 8 May 1815. He studied medicine and practised in Charleston, where he soon acquired celebrity. He was a field-surgeon in the Continental army, was elected to the State legislature in 1776, was a prisoner of the British in 1780-81 and in 1782-

86 served in the Continental Congress, acting as president in 1785-86. He was a member of the South Carolina legislature in 1801-15 and was president of the State senate when he was killed by a lunatic. He labored zealously with his pen to promote the cause of the American independence and among his publications are 'The History of the American Revolution' (1789); 'The Life of Washington' (1807); 'The History of South Carolina' (1785); 'Universal History Americanized, or an Historical View of the World, from the Earliest Record to the 19th Century' (12 vols. 1816-17), etc.

RAMSAY, Francis Munroe, American naval officer: b. Washington, D. C., 5 April 1835. He was appointed midshipman in 1850, was graduated from the United States Naval Academy in 1856, and in the Civil War participated in the engagements at Haines' Bluff, Yazoo River, Milliken's Bend and later commanded the gunboat *Unadilla* of the North Atlantic Squadron. He was superintendent of the United States Naval Academy in 1881-86, was promoted rear-admiral in 1894, served as chief of the Bureau of Navigation in 1889-97, and in the latter year was retired on reaching the age limit.

RAMSAY, Nathaniel, American soldier: b. Lancaster County, Pa., 1751; d. 25 Oct. 1817. He was graduated from Princeton in 1767, studied law, was admitted to the bar in 1771, and in 1776 entered the Continental Army with rank as lieutenant-colonel. He greatly distinguished himself at the battle of Monmouth in 1778, when he with Colonel Stewart checked the advance of the British while Washington rallied the main army. He was severely wounded, taken prisoner and held until 1780 when he was shortly afterward retired. With the exception of 1786-87, when he was a member of Congress from Maryland, he saw no further public service.

RAMSAY, Sir William, Scotch chemist, nephew of Sir A. C. Ramsay, the geologist: b. Glasgow, 2 Oct. 1852; d. 23 July 1916. He was educated at Glasgow and Tübingen, was assistant in the 'Young' chemical laboratory 1872-74, and at Glasgow University 1874-80, and after seven years as professor of chemistry at University College, Bristol (six as its principal), and from 1887-1913 was professor of chemistry at University College, London. A member of most of the royal academies, philosophical, physical and chemical societies of the world, he won his chief repute for his study of rare gases and their discovery; with Lord Raleigh in 1894 he discovered argon (q.v.) and alone isolated helium, krypton, neon and xenon (qq.v.). In the investigation of the nature and properties of radium he took a prominent part, and in November 1903 claimed that he had proof that helium is the gaseous emanation of radium (q.v.). In 1904 he was awarded the Noble prize in chemistry. He was created K.C.B. in 1902 and was an officer of the Legion of Honor and of the Prussian order *Pour le Mérite*. He wrote 'The Gases of the Atmosphere, the History of their Discovery' (1896). Consult Tilden, Wm. A., 'Sir William Ramsay' (1918).

RAMSAY, Sir William Mitchell, Scottish archaeologist and historian: b. Glasgow, 15 March 1851. He was educated at the univer-

sities of Aberdeen, Oxford and Göttingen, was Oxford traveling student in 1880 and from that date onward has traveled extensively in Asiatic Turkey. In 1885 he was appointed to the chair of classical archaeology at Oxford, and since 1886 has been professor of humanity (Latin) in the University of Aberdeen. He has made a special study of the geography and topography of Asia Minor, and among his works are 'The Historical Geography of Asia Minor' (1890); 'The Church in the Roman Empire before A.D. 170' (1893), dealing with Saint Paul in Asia Minor and the early persecutions of the Christians; 'The Cities and Bishoprics of Phrygia' (1895-97); 'Saint Paul the Traveler and the Roman Citizen' (1895); 'Impressions of Turkey' (1897); 'Was Christ Born at Bethlehem?' (1898); 'Historical Commentary on the Epistle to the Galatians' (1899); 'The Education of Christ' (1902); 'The Letters to the Seven Churches of Asia' (1905); 'Pauline and Other Studies in Early Church History' (1906); 'The Cities of Saint Paul' (1907); 'The Revolution in Constantinople and Turkey' (1909); 'Pictures of the Apostolic Church' (1910); 'The First Christian Century' (1911); 'The Teaching of Paul in Terms of the Present Day' (1913); 'The Making of a University' (1915).

RAMSDEN, rāmz'dēn, *Jesse*, English mechanist and optician: b. Halifax, Yorkshire, 6 Oct. 1735; d. Brighton, Sussex, 5 Nov. 1800. He was apprenticed to a cloth-worker, but subsequently applied himself to engraving and in the course of his employment having to engrave several mathematical instruments, finally constructed them himself. He opened a shop in the Haymarket, whence he removed to Piccadilly, where he remained until his death. Ramsden obtained a premium from the Board of Longitude for the invention of a machine for the division of mathematical instruments. He also improved the construction of the theodolite, the pyrometer for measuring the dilation of bodies by heat, the barometer for measuring the height of mountains, the refracting micrometer and transit instrument and quadrant. He made great improvements in Hadley's quadrant and sextant, reducing the limits of error from 5 minutes to 30 seconds; and procured a patent for an amended equatorial. He was chosen a Fellow of the Royal Society in 1786, and such was his reputation that his instruments were bespoken from every part of Europe. He received the Copley medal from the Royal Society in 1795 in recognition of the importance of his various inventions.

RAMSEUR, rām'sér, *Stephen Dodson*, American soldier: b. Lincoln, N. C., 31 May 1837; d. Cedar Creek, Va., 19 Oct. 1864. He was graduated from West Point in 1860 and was assigned to garrison duty at Fortress Monroe. At the outbreak of the Civil War he resigned from the United States army to enter the Confederate service with rank as major of artillery. He served in the Peninsular Campaign, was later attached to "Stonewall" Jackson's command, performed gallant service at Chancellorsville and at Gettysburg in his capacity of brigadier-general and was conspicuous for bravery in the battle of the Wilderness. In 1864 he received temporary rank as major-general, was engaged in the Shenandoah campaign and was fatally wounded at the battle of

Cedar Creek, where he was captured while covering the retreat of the Confederate forces.

RAMSEY, rām'zī, *Alexander*, American politician and Cabinet officer: b. near Harrisburg, Pa., 8 Sept. 1815; d. Saint Paul, Minn., 22 April 1903. He took a partial course at Lafayette College (Easton, Pa.), studied law at Carlisle, Pa., was admitted to practice in 1839; in 1841 was elected chief clerk of the Pennsylvania house of representatives and in 1843-47 was a Whig representative in Congress. In 1848 he was chairman of the Whig State committee, and on 2 April 1849 was appointed governor of Minnesota, established as a Territory 3 March 1849. He concluded treaties with the Ojibways and Sioux in 1851, and a second treaty with the Ojibways in 1863. In 1855 he became mayor of Saint Paul, in 1859 was elected governor of the State of Minnesota, being the Republican candidate for the first State campaign, and by re-election held the post until his resignation 10 July 1863. He then served in the United States Senate two terms, ending in 1875. While in the Senate he visited France in the effort to secure a cheaper rate of international postage. In 1879-81 he was Secretary of War in Hayes' Cabinet. He was a leading spirit of the Minnesota Historical Society, of which he was the first president (1849-63). He was the first Civil War governor to offer volunteers to Lincoln.

RAMSGATE, rāmz'gāt, England, on the Isle of Thanet, in the county of Kent, 65 miles east by south of London, is a seaport and popular seaside resort. It is situated in the valley between chalky cliffs and has a fine stretch of sandy beach. The chief places of interest are the theatre, music-hall, assembly-room, iron promenade pier and churches. There is an excellent harbor, extensive bathing establishments; of historical interest are an ancient Anglo-Saxon graveyard on Ossengal Hill, about one mile from the town; Pegwell Bay, the landing place of Hengist and Horsa, and Cliffs' End, where a cross marks that of Saint Augustine. There is some shipbuilding, rope-making and a considerable fishery. Pop. 29,603.

RAMUS, rā'mūs, *Petrus*. See **RAMÉZ**, **PIERRE**.

RANA. See **FROG**.

RANAVALONA III (also written **RAN-AVALO**), last queen of Madagascar: b. 1864. She succeeded her aunt, Ranavalona II, in 1883, and in that year married the Prime Minister, Rainilaiarivony, who had been prince consort to her aunt. She was only nominally queen, as the government had been controlled by the Prime Minister since 1864. The French succeeded in establishing a protectorate over the island in 1895, but Ranavalona retained a nominal sovereignty until 1897, when the island was declared a French colony and the queen was deposed and exiled to Algeria.

RANC, rānk, *Arthur*, French politician and author: b. Poitiers, 20 Dec. 1831; d. 10 Aug. 1908. He was educated at Poitiers; studied law in Paris; became involved in the disorders of the Democratic party, was arrested and deported to Africa. Returning to Paris after the

amnesty of 1859, he contributed to the *Courier du Dimanche*, the *Nain Jaune*, the *Journal de Paris* and other journals. For certain articles written for the *Nain Jaune* he was imprisoned for four months. Under Gambetta he became director of police and in 1871 was elected to the National Assembly, but owing to his disagreement with the arrangements for peace he resigned and was elected a member of the Commune. He resigned from that body on account of its violence. In 1873 he again became a member of the National Assembly. Later he was impeached for the part he had played during the Commune, and in 1875, during his absence in Belgium, was condemned to death in *contumaciam*. The amnesty of 1879 allowed his return to France, and in 1881 he became deputy from the Seine and in 1891 a senator. He succeeded Clemenceau as editor of *L'Aurore* and was later president of the Association of Republican Journalists. He wrote a political romance, 'Sous l'Empire' (1872), also 'De Bordeaux à Versailles' (1877); 'Le Roman d'une Conspiration' (1868).

RANCAGUA, rān-kāg'wā, Chile, the capital of the province of O'Higgins, 50 miles by rail south of Santiago. It is an agricultural centre with an active domestic trade. The Spaniards here won an important victory over the revolutionary forces in 1814. Pop. 10,380.

RANCÉ, rān-sā, Armand Jean le Bouthillier de, founder of the reformed order of La Trappe: b. Paris, 9 Jan. 1626; d. 26 Oct. 1700. At 11 he was appointed canon of Notre Dame, and at 13 wrote a commentary on the Odes of Anacreon. After being graduated at the Sorbonne, he was ordained priest (1651) and before long was preferred to no fewer than six benefices. Residing at Paris, in receipt of a large income in addition to his private fortune, he gave himself up to a life of dissipation. In 1657, however, a change took place in his manner of life, and he determined to enter the cloister. He disposed of his estate of Veret, near Tours, applying the proceeds to religious purposes, and demitted all his benefices except the priory of Boulogne and the abbey of La Trappe. Retiring to the latter place in 1664, he began the strictest reforms. (See LA TRAPPE). In consequence of his growing infirmities he resigned his charge of the abbey in 1695. Consult Marsollier, 'Vie de Rancé' (1703); Gailardin, 'Trappistes' (1844); Pfannenschmidt, 'Geschichte der Trappisten' (1873).

RANCHING, a term derived from the Spanish-American word "rancho," originally meaning a place where herdsmen eat and sleep, but gradually extended to mean a grazing farm. One who owns or operates a ranch is a rancher or ranchman, or in Mexico a *ranchero*. Some of these ranches are of vast extent, especially in Old Mexico and in South America, where they are termed *haciendas*, and include hundreds of square miles. In Texas, Colorado and other Western States and Territories, also, there are very large ranches, from which come the supplies of cattle for the American and foreign markets. With the growth of population there has been a marked reduction in great individual holdings of land, but some of the cattle-farms are still very extensive. The cattle are herded by a mixed class of men known as cowboys,

which includes students from college, rough and honest frontiersmen and others with a record that has driven them from places where they are better known. The cowboys round up the cattle once or twice a year, when the steers three years old are separated from the main herd and sent to market, and the calves are branded. The cattle of the ranches have been much improved within recent years by crossing with domestic breeds. It was chiefly from the cowboy element that President Roosevelt recruited his Rough Riders for the Spanish-American War.

RAND, Edward Kennard, American philologist: b. Boston, Mass., 20 Dec. 1871. He was graduated at Harvard in 1894 and later studied at the University of Munich, and the Episcopal Theological School at Cambridge, Mass. He was instructor in Latin at the University of Chicago in 1895-98, and occupied that position at Harvard in 1901-05, becoming assistant professor in 1905, and since 1909 he has been professor of Latin there. He is Harvard trustee of the American Academy at Rome, and in 1912-13 he was annual professor there. Author of articles on classical and mediæval subjects and joint author of 'Dante's Alagherii Operum Latinorum Concordantiæ' (1912). He also wrote 'Ovid and the Spirit of Metamorphoses' (1912).

RAND, rānd, contraction of WIT-WATERSRAND, South Africa. See WIT-WATERSRAND; TRANSVALL COLONY.

RANDALL, rān'dal, Alexander Williams, American statesman: b. Ames, N. Y., 31 Oct. 1819; d. Elmira, N. Y., 25 July 1872. He studied law, was admitted to the bar and in 1840 established a law practice at Waukesha, Wis. He was appointed postmaster there and in 1847 was a member of the convention which framed the State constitution. In 1855 he was elected to the State legislature, was judge of the second district in 1856, and in 1857-61 was governor of Wisconsin, rendering important aid in raising troops for the Union army. In 1861-62 he served as Minister to Italy, was Assistant Postmaster-General in 1862-66 and Postmaster-General in 1866-69. He then retired from public life and engaged in law practice at Elmira until his death.

RANDALL, George Morton, American military officer: b. Ohio, 8 Oct. 1841. At the outbreak of the Civil War he entered the Union army, where he received a commission as second lieutenant. He received steady promotion, was distinguished for gallantry at Antietam and Petersburg, and was mustered out of the volunteer service in 1865 with the rank of lieutenant-colonel. He was commissioned captain in the regular army in that year, promoted colonel in 1890 for gallant services in the Indian warfare in Arizona in 1873-74; commissioned brigadier-general of volunteers at the outbreak of the Spanish War in 1898, and on the reorganization of the regular army in 1901 received rank as brigadier-general.

RANDALL, James Ryder, American journalist and poet: b. Baltimore, Md., 1 Jan. 1839; d. Augusta, Ga., 14 Jan. 1908. He was educated at Georgetown College, D.C., taught for a while in a Louisiana college, and then turned to

journalism. In 1861 he wrote 'Maryland, My Maryland,' a song which when set to music became, next to 'Dixie,' the most popular of the Confederate war-songs and is considered by many to be the best American martial lyric. None of his other songs achieved the fame of this, but several of them are of notable excellence. Among them are 'Stonewall Jackson,' and 'There's Life in the Old Land Yet.' After 1866 he was for many years the editor of the *Constitutionalist* of Augusta, Ga., and later of the *Morning Star* of New Orleans.

RANDALL, Samuel Jackson, American statesman: b. Philadelphia, 10 Oct. 1828; d. Washington, D. C., 12 April 1890. Educated in the schools of his native city, he began life as a silk merchant's clerk and later entered into partnership in a firm of wholesale iron merchants. But politics was more attractive to him than business. He served four years as member of the city council and in 1858 was elected to the State senate. He enlisted with the City troop of Philadelphia at the beginning of the Civil War and served under General Thomas' command in the 2d United States Cavalry. He was promoted to orderly sergeant, then quartermaster and finally captain of his company. During the battle of Gettysburg he was advanced to provost marshal. In 1862 he was elected to Congress and was a member of that body for 28 years. The first eight years of his career in Congress were uneventful; but in the 43d Congress he served with Blaine, Garfield, Banks and S. S. Cox on the committee on rules and took the lead in the opposition to the Force Bill in order to defeat its passage as law and secure for himself the leadership of the Democratic party in Congress. He was elected speaker of the House at the second session of the 44th Congress and re-elected by the 45th and 46th; hence it fell to him to preside during the dispute over the Presidential election of 1876. He was not in sympathy with the settlement of the difficulty by means of an electoral commission. Although always a Democrat, he took the opposite view to that of his party on the subject of protection at the period when tariff discussions were uppermost in Congress. He was an indefatigable worker and never shirked the arduous labor of committees, insisting always on economy and honesty in the management of public affairs. Hence he served as an immense safeguard of the national treasury.

RANDEGGER, răn'dэг-gэр, Alberto, Austro-English composer and conductor: b. Trieste, 13 April 1832; d. 1911. He studied pianoforte under Lafont and composition under L. Ricci, and before he was 20 was known as composer of several masses and two ballets. His next work was an opera, 'Il Lazzarone,' to a libretto by Rossi. He became musical director in various Italian theatres and brought out his second opera, 'Bianca Capella,' at Brescia in 1854. In that year he removed to London, where he long resided, becoming naturalized. He was teacher and director of the Royal Academy of Music, conductor of Italian opera at Covent Garden and of concerts at Queen's Hall and the Norwich Festival. A comic opera, 'The Rival Beauties,' was produced in 1864. He was made Knight of the Crown of Italy in 1892.

RANDERS, răn'dэrs, Denmark, in Jutland, capital of the province of the same name, lies

at the head of Randers Fjord, about 20 miles from the Cattegat. It is an important port, whose chief exports are butter and eggs; chief imports sugar, petroleum, coal and iron. Its celebrated gloves, its manufacture of hosiery, cutlery, railway carriages, calico-printing works and distilleries are the chief industries. Pop. 22,963.

RANDOLPH, răn'dölf, Alfred Magill, American Protestant Episcopal bishop: b. Winchester, Va., 31 Aug. 1836. He was graduated at William and Mary College in 1855 and at the Virginia Theological Seminary in 1858, and took priest's orders in 1860. He was rector of Saint George's Church, Fredericksburg, Va., 1860-62, chaplain in the Confederate army 1863-65, and rector of Emmanuel Church, Baltimore, Md., 1867-83. In the latter year he was elected coadjutor-bishop of Virginia. In 1892 the diocese was divided and he then became bishop of southern Virginia. He has published 'Reason, Faith and Authority in Christianity' (1902).

RANDOLPH, Edmund Jennings, American statesman: b. Williamsburg, Va., 10 Aug. 1753; d. Clarke County, Va., 13 Sept. 1813. He was educated at William and Mary College and afterward admitted to the bar. He was Virginia's first attorney-general, was member of Congress, 1779-82 and governor of Virginia, 1786-88. He was a member of the convention that framed the Federal Constitution though he did not approve or sign the document when completed. However, he urged Virginia to accept it, feeling the necessity of union of the States. He was a leader in the work of codifying the Virginian laws begun in 1788. In 1789 Washington appointed him Attorney-General and in 1794 he succeeded Jefferson as Secretary of State. During the pending of the Jay treaty, Fauchet, the French Minister to the United States, sent home some dispatches to his country which were intercepted by an English ship and through the English Minister were transmitted to Washington. They were kept by the President for eight days before their contents were disclosed to Randolph. Feeling that others had been consulted regarding the matter before he was apprised and that he must consequently be prejudged, he resigned his office after denying the allegations of the dispatches. He retired to Virginia and resumed the practice of the law, but his public career was blighted and his memory bore the stain of the accusations against him until his vindication was presented by Moncure D. Conway in an article 'A Suppressed Statesman,' in *Lippincott's Magazine* for September 1887, followed by a biography, 'Omitted Chapters of History Disclosed in the Life and Papers of Edmund Randolph' (1888).

RANDOLPH, Edward, British colonial agent: b. England, about 1620; d. West Indies after 1694. He was sent to New England in 1676 with a governmental commission to obtain information concerning the resources and the general character of the leading men in the colonies. He was also the representative of Capt. John Mason who claimed the ownership of New Hampshire. Randolph's arrogant demands, overriding the charter of Massachusetts caused Governor Leverett to refuse to recognize him as a royal agent. Randolph, on his return to England after a six weeks' stay, pre

seated a report hostile to the public men of the colonies and greatly exaggerating the population and wealth of the country, in order to afford an excuse for increased taxation. In 1678 he was appointed collector and surveyor of customs for New England. In the nine years of his tenure of office he made eight visits to England, and his misrepresentations were largely responsible for the abrogation of the Massachusetts charter in 1684. He served under Gov. Sir Edmund Andros in 1686-89, and upon the overthrow of the Andros administration he was imprisoned but later was released. He went to the West Indies in 1694, and died there. A complete list of Randolph's reports is given in the 'Andros Tracts' (Vol. III).

RANDOLPH, John, of Roanoke, American statesman: b. Cawsons, Chesterfield County, Va., 2 June 1773; d. Philadelphia, 24 June 1833. He was of an old and wealthy Virginia family and claimed to be a descendant of Pocahontas. His father died young, and his mother married St. George Tucker, who directed his early education. Later he attended the grammar school of William and Mary College; in 1787 went to Princeton for a few months, and the following session to Columbia College, which ended his academic training. In spite of his protestations of ignorance he was well educated, and wrote and reasoned well. He read law and began to practise, but preferred politics, and in 1799 was elected to Congress on a platform denouncing the Alien and Sedition laws. Randolph was in the House of Representatives 1799-1813, 1815-17 and 1819-25. He was a member of the Senate, 1825-29, and in 1829 was a member of the Virginia Constitutional Convention. In Congress he soon became the leader of the Democratic-Republican opposition, and after the defeat of the Federalists was the leader of the administration party, but soon fell out with Jefferson, and became an independent with a few followers called "Quids." Throughout his public career Randolph was a consistent, strict constructionist. In his first speech he advocated a reduction of the "mercenary" army; he led in the impeachment (1804-05) of Justice Chase, of the Federal District Court; he denounced the settlement of the Yazoo frauds; and was the enemy of fraud and corruption in every form. Brought up in the midst of war, he hated it, opposing all measures leading to the War of 1812, and his opposition to the administration cost him his seat in 1813. Returned to Congress in 1815, he strongly opposed the national reaction that followed the War of 1812. He disliked slavery, but denounced the Missouri Compromise as a surrender of principles by both sides. He invented the term "dough faces," as applied to Northern men who made compromise with slavery for reasons of expediency. He supported Jackson for the Presidency, and denounced the Adams-Clay understanding as "a combination of Puritan and blackleg." A duel with Clay followed (1825), in which Randolph threw away his fire and offered Clay his hand. In 1830 Jackson appointed him Minister to Russia. Resigning because of ill health, Randolph returned to America (1831) and opposed Jackson in the Nullification controversy. Re-elected to Congress in 1832, he died before taking his seat. Randolph was a strange compound of

contradictory elements. At times he was a deist; oftener an emotional Christian. He was a far-sighted statesman, an eloquent speaker, a master of satire and vindictive; at times he spoke nonsense. Eccentric and irritable in public, at odds, sooner or later, with all of his associates and colleagues, he was fond of children and was loved by them. By his will he emancipated his 318 slaves, providing for their support. With clearer vision than most of his contemporaries, he foresaw the grave danger to the South from the slavery question in politics and pointed out the course which that section must follow. He was never married, his fiancée, the beautiful Maria Ward, having broken her engagement with him to marry his cousin, Peyton Randolph. An aristocrat, he believed in the democratic theories of the French Revolution, but admired Edmund Burke. In his later years, his mind was affected by disease and the use of drugs to deaden pain, and by domestic troubles. In personal appearance Randolph was tall, very slender, with a dark, keen face and long thin fingers, which he pointed or shook at his opponents when speaking. "Little Jack" was a beautiful boy; John Randolph was an ugly man. Consult Garland, 'The Life of John Randolph of Roanoke' (1881); Adams, Henry, 'John Randolph' (1882); Trent, 'Southern Statesmen of the Old Régime' (1898).

WALTER L. FLEMING,

Professor of History, Vanderbilt University.

RANDOLPH, Peyton, American patriot, president of the first Continental Congress: b. Williamsburg, 1723; d. Philadelphia, 22 Oct. 1775. He was graduated at William and Mary College and, sent to complete his education in England, studied law at the Temple. In 1748 he became king's attorney for the colony and the same year was chosen a member of the house of burgesses. He was chairman of a committee authorized to revise the laws of the colony, and was among the most active and influential members of the assembly. In 1764 the Virginia house of burgesses voted an address to the king against the passage of the Stamp Act, which Randolph drew up. On 12 April 1766 he was made speaker of the house of burgesses, and resigned his office of attorney-general. In the measures of opposition to the English he now took a conspicuous part. In March 1773, on the reception of copies of an address and resolution from the Massachusetts assembly, Randolph was prominent in urging instant and bold action. In the convention which met in August 1774, at Williamsburg, he presided, and was one of the delegates elected to the Continental Congress appointed to meet in Philadelphia in the following September. On the assembling of that body he was unanimously elected its president. In 1775 he presided over the second convention of Virginia and was speaker of the house of burgesses.

RANDOLPH, Thomas Jefferson, American legislator: b. Monticello, Albemarle County, Va., 12 Sept. 1792; d. Edge Hill, Albemarle County, Va., 8 Oct. 1875. He was for several years a member of the State legislature of Virginia, where he introduced in 1832 a bill for the gradual abolition of slavery, and in 1842 another for the reform of the taxes, which was passed, and proved of assistance in placing the State on a sound financial basis. In 1851-

52 he was a member of the convention for the revision of the Virginia constitution, in Civil War time was a firm supporter of the Confederacy and in 1872 presided over the National Democratic Convention which nominated Horace Greeley for the Presidency. He edited the 'Life and Correspondence of Thomas Jefferson' (his grandfather) (1829); and wrote also 'Sixty Years' Reminiscences of the Currency of the United States.'

RANDOLPH, Mass., town in Norfolk County, 15 miles by rail south of Boston, on the New York, New Haven and Hartford Railroad. The Boston School for the Deaf is located here. Manufactures include shoes and boxes. Pop. 4,301.

RANDOLPH, Vt., town in Orange County, on the Central Vermont Railroad, about 25 miles south by west of Montpelier. The town includes Randolph Centre and North Randolph. It is in an agricultural and lumbering region and its industries are connected largely with farming and lumbering. It has woodenware factories, flour and lumber mills and creameries. Its most noted institution is the Randolph State Normal School. It has a free public library. Pop. of the town, 3,191; of the Centre, 1,787.

RANDOLPH-MACON SYSTEM OF COLLEGES AND ACADEMIES, a group of five institutions in Virginia, comprising (1) Randolph-Macon College at Ashland, a college for men; (2) Randolph-Macon Academy at Bedford City, and (3) Randolph-Macon Academy at Front Royal, preparatory schools for boys; (4) Randolph-Macon Woman's College at Lynchburg; (5) Randolph-Macon Institute at Danville, a preparatory school for girls. These institutions are under the control of one board of trustees, which is self-perpetuating. The original institution is the college for men at Ashland, which was established under the auspices of the Methodist Episcopal Church, South, and received its charter from the Virginia legislature in 1830, thus being the oldest Methodist college in America. It was located near Boydton, Mecklenburg County, Va., and opened to students in 1832. The college obtained no permanent endowment until shortly before the Civil War, and was closed during the war. Much of the endowment was also rendered worthless, and the college reopened in 1866 under serious embarrassment. In 1868 its site was changed to Ashland, Va., and since that time its work has been successful and influential. The first of the affiliated schools was the Academy of Bedford City, founded in 1890; the academy at Front Royal was established in 1892, and the woman's college in 1893; the institute at Danville was affiliated with the system in 1897.

The Randolph-Macon College at Ashland offers courses leading to the degrees of A.B. and A.M.; graduation with distinction in four subjects additional to those required for the degree of A.B. is required for the degree of A.M. The A.M. courses are elective, and the elective system prevails to a limited degree in the A.B. course. Six students' aid funds are provided, four of which are for ministerial students, and several scholarships, the largest of which has a fund of \$10,000. Two literary societies are maintained by the students for literary and ora-

torical exercises. The buildings include Pace lecture-room building, the chemical laboratory, Duncan Memorial Chapel, the library, the gymnasium, the Pettyjohn Hall of Science and eight large dormitories. The library contained in 1917 16,500 volumes. The students in 1917 numbered 186, and the faculty 18.

The Randolph-Macon Woman's College offers courses leading to the degrees of A.B. and A.M. One year of graduate work in courses elected by the student is required for the master's degree. For the A.B. course the work of the first two years is prescribed, the last two years is largely elective; the electives are arranged in eight groups, one course in each group being the free choice of the student. Courses in music are offered; one course in the history of music is open to all college students and counts toward the A.B. degree; and a completion of the course in either piano, organ or vocal music counts three hours toward the degree. The college occupies two large buildings, the main building and the Jones Memorial Library; the library contained 15,000 volumes in 1917; 604 students were enrolled and 49 instructors.

RANDOLPH PLAN, in American political history, the name given the scheme of a Federal Constitution proposed in the Convention of 1787 by Edmund Randolph of Virginia. It contained 15 resolutions and proposed a correction of the Articles of Confederation; representation by population in two branches of Congress, the first chosen by the people, the second by State legislatures; Congressional control of taxation and commerce; Congressional veto of State enactments; that Congress should choose the executive; that the executive with part of the judiciary should have a limited veto on acts of Congress and other less important provisions. The plan was favorably reported and many of its suggestions were used in the drafting of the Constitution.

RANELAGH, rān'ē-lā, a fashionable London pleasure resort of the 18th century, frequently referred to in English literature. The rotunda built on the model of the Pantheon at Rome accommodated 6,000 persons and stood in beautiful gardens. The grounds are now occupied by the Chelsea Hospital.

RANGE, (1) in *gunnery*, the horizontal distance to which a projectile is thrown. Strictly, it is the distance from the muzzle of the gun to the second intersection of the trajectory with the line of sight. The range of a cannon lying horizontally is called the *right level* or *point-blank range*; when the muzzle is elevated to 45 degrees it is called the *utmost level*. (2) In *music*, the whole ascending or descending series of sounds capable of being produced by a voice or instrument; the compass or register of a voice or instrument. (3) In *natural science*, the geographical limits within which an animal or plant is now distributed, and the limits in point of time within which it has existed on the globe. The first is called *range in space* and the second *range in time*. In the case of marine animals, as the Mollusca, there is also a *range of depth*, as measured by the number of fathoms which constitute their superior and inferior limits. (4) As a nautical term, the length of cable a little

in excess of the depth of water, ranged on deck ready to run out when the anchor is let go. Also a large cleat in the waist for belaying the sheets and tacks of the courses. (5) A target range is a place prepared for shooting at a target.

RANGE FINDER. See FORTIFICATIONS.

RANGELEY (rānj'li) LAKES, in Maine, near the western boundary: one of the lakes, Umbagog, is on the boundary between Maine and New Hampshire. The principal lakes are Umbagog, Richardson, Molechunkemunk, Mooselookmaguntic, Rangeley and Kennebago. A number of small bodies of water are connected with the lakes mentioned and all are joined by short streams. The Rangeley Lakes are at the headwaters of Androscoggin River. They are noted for the wild and picturesque scenery and the abundance of fish and game. The region is a favorite summer resort. Two railroads enter this section, one terminating at the town of Rangeley on Rangeley Lake and the other at Bemis on Mooselookmaguntic Lake.

RANGER, rān'jer, Henry Ward, American painter: b. western New York, 1858. He never attended an academy of art, but traveled through France, England and Holland for several years and returning to the United States was elected associate of the National Academy of Design. Among his pictures are 'The Top of the Hill' (in the Corcoran Gallery); 'East River Idyll' (in the Carnegie Gallery); 'Pasture Lot'; 'Morning at High Bridge' and 'Spring Woods' (in the Metropolitan Museum, New York); 'Bradley's Mill Pond' (in National Gallery, Washington, D. C.). Some of his pictures are marines, and as a landscape painter his works are fresh, vigorous and finely colored.

RANGOON, rān-goon', Burma, chief town and principal seaport of Lower Burma, on the left bank of the Hlaing or Rangoon River, in the Pegu division, covers an area of 22 square miles, and is populated by Hindus, Mohammedans and Christians. The town occupies a long stretch of high land, incorporating villas whose spacious grounds lend to certain parts almost a rural aspect. The wide streets are virtually boulevards bordered on either side by trees. The modern large town is of recent growth, dating from the British occupation in 1852. Among the buildings may be mentioned the cathedrals, churches, government buildings, town-hall, law-courts, custom-house, hospital schools and colleges and museum. The city enjoys most of the modern conveniences, including a good water supply. There is railway communication with Mandalay and Prome. A large foreign and inland commerce is also carried on by waterways. The main exports are rice and timber, besides raw cotton, precious stones, ivory, horns and a variety of other articles. Cotton and woolen goods, machinery, coal, silk, salt and sugar are imported. The annual exports exceed £10,000,000. Rangoon was built in 1753 by Aloung-Choosa, the founder of the Burmese dynasty, and has since been the scene of many wars between Burmans and Peguans. The British restored it in 1825 to the Burmese, but annexed it in 1852. Pop., including cantonment, 293,316.

RANJIT SINGH, rān-jēt' sing'h', founder of the Sikh kingdom in the Punjab, India: b. Gujranwala, 2 Nov. 1780; d. 27 June 1839. His father was Maha-Singh, sirdar of Sukur Chu-keah. He lost both parents before he was 18, and though wholly without education set vigorously about consolidating and extending his power. At 20 he was appointed governor of Lahore by the Afghan Amir and calculated upon the fanaticism of the Sikhs for establishing his power over them. He secured European officers to organize his army, whose steadfastness and religious zeal, Sir William Hunter has compared to the Ironsides of Cromwell. In 1809 he formed an alliance with the English through Charles Metcalfe, defining the Sutlej as the boundary between their respective territories, and to this engagement he always remained loyal. Having removed the danger of English combination with any of his native rivals, he actively pushed forward his conquests until his territory extended to and embraced Multán on the south, Pesháwar on the west and Kashmir on the north. He obtained from Sháh Shujá, a refugee in Lahore, the Kohinur diamond that had been carried off by Nádir Sháh from Delhi. Dissensions followed his death, as none of his sons was capable of continuing his rule. Consult Griffin, 'Ranjit-Singh' (1892); Gordon, 'The Sikhs' (London 1904); Burgess, 'Chronology of Modern India' (Edinburgh 1913).

RANK, in the army and navy, is officially described as "that character or quality bestowed on military persons which marks their station and confers eligibility to exercise command or authority in the military service within the limits prescribed by law." It is divided into degrees or grades which mark the relative positions and powers of the different classes possessing it. Rank is generally held by virtue of office in an arm of the service, corps or department, but may be conferred independently of office, as in the case of retired officers and of those holding it by brevet. While the President of the United States is technically commander-in-chief, the highest rank in the American army is general; in the navy, admiral. Next to general is lieutenant-general, then major-general and next brigadier-general. In time of peace the highest army officer is usually a major-general, the titles of general and lieutenant-general being bestowed only as marks of special distinction. The same conditions apply to the ranks of admiral and vice-admiral. Until 1917 there had been only four "full" generals in the American army—Washington, Grant, Sherman and Sheridan; and three "full" admirals in the navy—Farragut, David Porter and Dewey. The title of general lapsed with the death of Sheridan in 1888, and under the law of 1911 the rank of admiral ceased on the death of Dewey, 16 Jan. 1917. Besides the four generals mentioned, the rank of lieutenant-general has been held also by J. M. Schofield, Nelson A. Miles, S. B. M. Young, A. R. Chaffec, John C. Bates, H. C. Corbin, A. McArthur and Winfield Scott (brevet). By act of Congress, 22 May 1917, provision was made for the appointment of three admirals and three vice-admirals; and another act, 6 Oct. 1917, revived the title of general for two officers, namely, the chief of

staff and the commander of the United States forces in France. The application of both statutes, however, extends to "the existing emergency only"—the European War, the object being to place the American war chiefs on a rank level with that existing among the allied naval and military forces. The relative rank between officers of the army and navy is as follows, lineal rank only being considered: General with admiral; lieutenant-general with vice-admiral; major-general with rear-admiral; brigadier-general with commodore (the latter grade ceased to exist in the United States navy 3 March 1899); colonel with captain; lieutenant-colonel with commander; major with lieutenant-commander; captain with lieutenant; first lieutenant with lieutenant (junior grade), and second lieutenant with ensign. An American general wears on his uniform the United States coat of arms and two silver stars; a lieutenant-general, one large silver star and two small ones; a major-general, two silver stars; a brigadier-general, one silver star; a colonel, one silver spread-eagle; a lieutenant-colonel, a silver leaf; a major, a gold leaf; captain, two silver bars, and a first lieutenant, one silver bar. The naval officers have similar decorations plus an anchor. The lowest military commissioned rank is second-lieutenant; in the navy, ensign. Brevet rank is the title of a rank superior to that actually held, without its pay or emoluments. At the close of the Civil War nearly all colonels, with good records, were brevetted brigadier-generals. See ARMY.

In the British navy and army the relative rank is almost the same except in the two highest grades, where an admiral of the fleet ranks with field-marshal; then admiral with general, etc.

RANKE, rān'kē, Leopold von, German historian: b. Wiehe, Thuringia, 21 Dec. 1795; d. Berlin, 23 May 1886. His preliminary education at Donndorf and Sculpforta was followed by courses in theology and philology in Leipzig. From 1818 to 1825 he taught classics in the gymnasium at Frankfurt, and then became professor of history at Berlin, largely because of the promise of his 'History of the Roman and Germanic Peoples from 1494 to 1535,' of which the first volume appeared in 1824. His coming to Berlin was the beginning of his study of Venetian history, which was chiefly due to his discovery of the valuable 'Relations of the Venetian Ambassadors,' a discovery which strengthened his belief in the importance of diplomatic and other documentary material. In 1827 he began the important study of civilization, first entitled 'Princes and Peoples of Southern Europe in the 16th and 17th Centuries,' and in its revised form called 'The Ottomans and the Spanish Monarchy in the 16th and 17th Centuries' (1877); and in the years immediately following wrote on the Serbian Revolution (1829); 'The Conspiracy against Venice in 1618' (1831), and the lectures 'On the History of Italian Poetry' (1837). To the lectures delivered in 1833 may be dated the rise of the historical school known by his name, which, like the Heidelberg School, was Protestant in sympathy and impulses, but unpartisan in methods; its members include Waitz, best known for his studies of constitutional history, Giesebrecht, who wrote on the German Empire,

von Sybel, author of the 'History of the French Revolution,' von Sybel's pupils, von Noorden and Maurenbrecher, and Dümmler, one of the editors of the 'Monumenta Germaniae,' and Dove, Ranke's literary executor and one of the editors of volumes 7-9 of the 'History of the World.' From 1833 also dates the foundation of the 'Historisch-Politische Zeitschrift,' edited by Savigny, Ranke and others, and protesting against the extreme liberalism of the revolution of July; as well as the beginning of Ranke's great history of 'The Roman Popes in the Last Four Centuries' (1834-37; 10th ed. 1900), with its clear outline of the varied political and religious influences at work in Rome and its wonderful grasp of the meaning in a philosophic scheme of 'World-History' of the Papacy. It was followed and balanced by 'German History in the Time of the Reformation' (1839-47; 7th ed., 1894), and 'Twelve (originally Nine) Books of Prussian History' (1847-48; revised 1878-79), thus fulfilling in part his function as Prussian historiographer, a post to which he had been appointed in 1841. He was ennobled by the King of Prussia in 1865, and since 1858 had been president of the Munich Historical Commission. His academic activity ceased in 1871, but his work of research, authorship and revision continued almost to the very day of his death. A monument was erected to him in Wiehe in 1896.

He wrote 'French History, Especially in the 16th and 17th Centuries' (1852-61); 'English History in the 16th and 17th Centuries' (1859-67; revised and enlarged 1877-79), and various studies in German history, among which the sympathetic 'History of Wallenstein' (1869; 5th ed., 1895) should be mentioned. But of the greatest importance as embodying Ranke's philosophical idea of universal history is the 'History of the World' (1880-88; 5th ed., 1896 seq.), which is marked by thorough research, excellent critical judgment and sharp, clear and felicitous characterization, with a poetical vigor of style.

Ranke's complete works were edited by Dove; volumes 53 and 54 contain valuable autobiographical matter. Consult also Dove's biography in the 'Allgemeine deutsche Biographie'; sketches by Sybel in 'Histor. Zeitschrift,' Vol. 56; Prutz, in 'Unsere Zeit' (1886), and his son F. v. Ranke, in 'Deutsche Revue' (1903); Lorenz, 'Ranke, die Generationenlehre und der Geschichtsunterricht' (1891); Guglia, 'Leopold von Ranke' (1893); Ritter, 'Ranke: Seine Geistesentwicklung und seine Geschichtschreibung' (1896); Nalbandian, 'Ranke's Bildungsjahre und Geschichtsauffassung' (1901).

RANKIN, Arthur McKee, American actor: b. Canada, 1841; d. San Francisco, Cal., 17 April 1914. His first appearance on the stage was at Rochester, N. Y., under the name of George Henley. He afterward resumed his own name and in the early '60s made his début in London. In 1870 he appeared in New York with Lydia Thompson. His most famous rôle was in 'The Two Orphans,' and he was also highly successful in 'The Danites,' a dramatized version of Joaquin Miller's novel 'The First Families of the Sierras.' Later he appeared chiefly in Shakespearian rôles. In 1881 he opened Rankin's Theatre in New York.

RANKIN, Jeannette, American member of Congress: b. near Missoula, Mont., 11 June 1880. She lived on a ranch until 15; received the degree of B.S. at the University of Montana in 1902, and in 1908-09 was a student at the New York School of Philanthropy. In 1909 she was engaged in social work in Seattle and in the following year was active in the suffrage movement in Washington State, in California in 1911 and in Montana in 1912-14. Her gifts as a campaign speaker made her welcome everywhere and in 1915 she visited New Zealand and worked as a seamstress in order to gain personal knowledge of social conditions. In November 1916 she was elected member at large from Montana to the 65th Congress (1917-19), being the first woman ever elected to the Congress of the United States. She was a senatorial candidate in 1918 but failed of election.

RANKIN, Jeremiah Eames, American Congregationalist clergyman and educator: b. Thornton, N. H., 2 Jan. 1828; d. Cleveland, Ohio, 28 Nov. 1904. He was graduated from Middlebury College, Vermont, in 1848 and entered the ministry, serving in various pastorates in Massachusetts, New York and New Jersey. From 1889-1903 he was president of Howard University, Washington, D. C., resigning in the latter year. He was the author of numerous hymns, notably 'God be with You,' and also published 'Auld Scotch Mither and other Poems'; 'Christ His Own Interpreter,' etc.

RANKIN, Pa., borough in Allegheny County, on the Monongahela River, eight miles from Pittsburgh, on the Baltimore and Ohio, the Pittsburgh and Lake Erie and the Bessemer and Lake Erie railroads. It is a growing town and manufactures steel and wire. Pop. 6,042.

RANKINE, rān'kin, William John MacQuorn, Scottish scientist: b. Edinburgh, 5 July 1820; d. Glasgow, 24 Dec. 1872. He entered Edinburgh University, where he gained several prizes in the department of physics; in 1837 he took up civil engineering and in 1842 published his first book, 'An Experimental Inquiry into the advantage of Cylindrical Wheels on Railways.' In 1848 he began his researches in the domain of molecular physics, which occupied him at intervals throughout his life and form his chief claim to distinction in the domain of pure science. In 1855 he was appointed to the chair of engineering in Glasgow University, which position he held until his death. He published 'Manual of the Steam-Engine and other Prime Movers' (1859); 'Manual of Civil Engineering' (1861); 'Treatise on Shipbuilding, Theoretical and Practical' (1866); 'Machinery and Millwork' (1869). Consult memoir by Tait prefixed to his 'Miscellaneous Scientific Papers' (1881).

RANNEY, William, American artist: b. Middletown, Conn., 9 May 1813; d. West Hoboken, N. J., 18 Nov. 1857. He learned drawing in Brooklyn, N. Y., and at the outbreak of the war with Mexico enlisted with the Texans. During the campaign he made sketches from the picturesque southwestern life, and after his return to Brooklyn, elaborated these into oil paintings of great interest, among which may be mentioned 'Boone's First View of the Kentucky'; 'On the Wing'; 'Washington on His

Mission to the Indians' (1847); 'Duck-Shooting' (Corcoran Gallery, Washington); 'The Sleigh Ride,' and 'The Trapper's Last Shot.'

RANOUS, Dora Knowlton, American writer and editor and translator: b. Ashfield, Mass., 16 Aug. 1859; d. New York City, 19 Jan. 1916. She married William V. Ranous in 1881. She went upon the stage, in the famous Daly Company, in 1879, but retired when she married. When it was necessary to support herself, she became assistant editor in a house that published textbooks. From this she passed to the editing, and to a large extent translating of the works of Maupassant, Daudet, Flaubert, and Disraeli. In collaboration with Rossiter Johnson she edited 'The Literature of Italy' (16 vols., 1906). She also edited many other works, including an elaborate cable code for the use of missions; and served on the staffs of the *Century Magazine* and the *Standard Dictionary*. She published anonymously 'The Diary of a Daly Débutante' (1910), and 'Good English in Good Form' (1916), and contributed many original articles to the 'Foundation Library for Young People' (1911) and to other publications.

RANSDALL, Joseph Eugene, American legislator: b. Alexandria, La., 7 Oct. 1858. He was graduated at Union College in 1882, was admitted to the bar in 1883, and was engaged in practice at Lake Providence, La., in 1883-99, since which time he has been interested in cotton planting. He served in Congress in 1899-1913, and was elected United States Senator for two terms (1913-25). He has been president of the National Rivers and Harbors Congress since 1907, and has also been honorary chancellor of Union College since 1907.

RANSOM, Matthew Whitaker, American soldier and legislator: b. Warren County, N. C., 8 Oct. 1826; d. 8 Oct. 1904. He was graduated from the University of North Carolina in 1847, was admitted to the bar the same year and in 1852 was elected attorney-general but resigned in 1855. He entered political life and in 1858-60 served in the State assembly. He was untiring in his efforts to avert the Civil War, but when North Carolina seceded he entered the Confederate army and served with ability through the war, attaining the rank of major-general in 1865. Afterward he resumed his law practice, was elected United States Senator in 1872 and served until 1895, when he was appointed Minister to Mexico and served until 1897 when he returned to the United States and re-engaged in law practice at Weldon, N. C.

RANSOM, Robert, American soldier: b. Warren County, N. C., about 1828; d. 1893. He was graduated from West Point in 1850, was breveted second lieutenant of dragoons and served in various parts of the West until appointed assistant instructor of cavalry tactics at West Point. He was made captain of the 1st cavalry 31 Jan. 1861, but resigned on 24 May and entered the Confederate army. He became colonel of the 9th North Carolina Confederate cavalry; in March 1862 was advanced to brigadier-general and on 26 May 1863 to major-general. In 1862 he commanded a brigade and the defenses near Kingston, N. C., and from April to June 1864 the Department of Rich-

mond. He was in command in November 1864 of the sub-district No. 2 of the Department including South Carolina, Georgia and Florida. At the close of the war he became express agent and city marshal of Wilmington, N. C., 1866-67; a farmer in Virginia, 1874-78, and later a civil engineer in the service of the United States in various river and harbor improvements in Missouri and South Carolina.

RANSOM, Thomas Edward Greenfield, American military officer: b. Norwich, Vt., 29 Nov. 1834; d. Rome, Ga., 29 Oct. 1864. He was educated at the Norwich University, studied civil engineering and settled in Illinois, where he engaged as a civil engineer and a real estate agent. After the outbreak of the Civil War he became a lieutenant-colonel of volunteers in July 1861, and commanded a regiment at Shiloh in April 1862. He was promoted brigadier-general in January 1863; served under General Banks in the Red River expedition, and later joined Sherman's army, took command of a division just before the capture of Atlanta, 2 Sept. 1864 and died as a result of overtaking his strength while leading his troops in pursuit of Hood.

RANSOM (from Latin, *redemptio*), the sum required to be paid to the captors of a prisoner of war in order to procure his release. The practice of redeeming prisoners of war by a ransom was a very common one not only in ancient times, but in modern times up to the end of the 18th century. As late as 1780 a treaty was concluded between France and Great Britain on the subject of exchange of prisoners, in which the various relations the different ranks bore to each other were specified, together with the sums required to be paid by way of ransom. A French vice-admiral or an English admiral was estimated as of equivalent value in the exchange of prisoners to 60 sailors or private soldiers, as was also a French marshal or an English field-marshal. Ransom is now exacted only by brigands. Prisoners are generally retained until peace is restored, when they are released without ransom, or they may be exchanged during the progress of hostilities. Officers are frequently released during the war on pledging their word of honor to take no further active share in it.

RANSOME, rân'süm, Arthur, English physician: b. Manchester, 11 Feb. 1834. He was educated at Trinity College, Dublin, Caius College, Cambridge and studied medicine in London and Paris. He was lecturer on biology at Cambridge in 1857-61, professor of hygiene at Owens College in 1880-95, became lecturer on phthisis at the College of Physicians in 1890 and is a recognized authority in pulmonary diseases. He has published 'Stethometry' (1876); 'Causes of Consumption' (1884); 'The Principles of Open Air Treatment of Phthisis and Sanatorium Construction' (1903); 'A Campaign against Consumption' (1914).

RANSOME, Frederick Leslie, American geologist: b. Greenwich, England, 2 Dec. 1869. He was graduated at the University of California in 1893, and in 1893-95 was Fellow in geology there. Ph.D. University of California 1896. In 1897-1900 he was assistant geologist and since 1900 he has been geologist of the United States Geological Survey. Since 1912

he has been in charge of the sections of western areal geology and metalliferous deposits. He was lecturer on ore deposits at the University of Chicago in 1907 and Silliman lecturer at Yale in 1913. He is president Washington Academy of Sciences, treasurer National Academy and treasurer National Research Council.

RANTERS, a term not in use in the United States, but formerly applied in England to the Primitive Methodists, on account of the enthusiasm and earnestness which characterized their worship. While this is the recent application of the word, it was formerly used in the period of the English Commonwealth to indicate an alleged sect whose practices attracted public reprobation and which was suppressed by the authorities.

RANTOUL, rân'tool, Robert, Jr., American statesman: b. Beverly, Mass., 13 May 1805; d. Washington, D. C., 7 Aug. 1852. His father, who survived him for several years, was long a member of the State legislature. The son was educated at Harvard where he was graduated in 1826. He studied law in Salem, was admitted to the Essex bar in 1827 and for several years practised in Gloucester, which he represented in the legislature 1834-37, and distinguished himself there as a reformer and an advocate of the rights and interests of the common people. He exerted himself for the abolition of capital punishment and made a report to the legislature on that subject. In 1837 he was appointed a member of the Massachusetts board of education and gave much time and attention to the advancement of the system of public instruction. In 1843 he became collector of the port of Boston and in 1845 was made United States district attorney. In 1851 he was elected United States Senator to succeed Daniel Webster for the short remainder of his term, and having been prominent among opponents of the extension of slavery, the Free-Soilers of his district united with the Democrats in electing him to the United States House of Representatives the same year. A volume of his speeches and writings with memoir appeared in 1854.

RANUNCULACEÆ, the buttercup family, composed of herbs and shrubs. There are about 800 species, widely distributed in cold and temperate climates and to a very limited extent in warm ones. All are more or less acrid while fresh, but usually lose this property upon being dried. A few have been reputed poisonous, others have been used in medicine and several for food both for man and animals. The family is, however, chiefly noted for its ornamental species, many of which are widely popular garden flowers. The best known of these genera are probably *Aquilegia*, *Clematis*, *Anemone*, *Delphinium*, *Hellebarus*, *Paeonia*, *Nigella*, *Caltha*, *Aconitum*, *Actæa* and *Ranunculus*. (See COLUMBINE; ANEMONE; LARKSPURS; PEONY; CLEMATIS; HELLEBORE). The type genus, *Ranunculus*, which includes about 200 species, is also cultivated. The garden or Asiatic ranunculus (*R. asiaticus*) is a native of western Asia and has been cultivated for about 300 years for its brilliant single or double variously colored flowers. The lesser celandine (*R. ficaria*), a European species, is cultivated for its foliage,

which is eaten like spinach and for its tubers, which are served like potatoes. Several species of buttercups, notably *R. acris* and *R. repens*, are well-known weeds in pastures.

RANZ DES VACHES, *rânz dâ vâsh*, "the lowing of the cows," the popular title of the simple melodies which the herdsmen of the Alps in Switzerland sing or play on an instrument called the alpenhorn when they drive the herds. It consists of a few simple intervals, yet capable of producing a very striking effect in the echoes of the mountains. Consult 'Sammlung von Schweizer Kuhreigen und Volkshiedem' (Berne 1818). See NATIONAL HYMNS.

RAOUL ROCHETTE, *râ-ool rô-shët*. See ROCHETTE, DÉSIRÉ RAOUL.

RAOULT, *râ-oo*, François Marie, French chemist: b. Fournes, Nord, 10 May 1830; d. 1901. He was educated in Paris, where he received the doctorate in physical sciences in 1863. He went to the University of Grenoble to teach chemistry, was made professor in 1870 and dean of the faculty in 1889. In 1890 he was made correspondent of the Academy of Sciences. His researches were first in the field of electro-chemistry; later he turned to the discovery of the freezing-point of a great number of solutions and also the determination of the tension of vapors of volatile liquids.

RAOULX, *râ-oo*, Jean, French painter: b. Montpellier, 12 June 1677; d. Paris, 10 Feb. 1734. He painted history, portraits and genre, and during his lifetime enjoyed a great reputation in France and was even elected to the Academy (1717). He has indeed painted some good landscapes in the style of Claude Lorraine, but his historical pictures are stogy and artificial. His portraits are said to have been good likenesses, and he is chiefly known nowadays for his portraits of fine ladies, on whom he bestowed the false and meretricious graces fashionable in his day. Many of his pictures were engraved.

RAP, familiar in the phrase "not worth a rap," a counterfeit Irish coin of the time of George I, which passed for a half-penny, though not really worth a fourth of that value. There was also a small Swiss coin called "rap-pen," worth a centime.

RAPE, an annual herb (*Brassica napus*) of the order *Cruciferae*. It is a native of the Old World, where it has long been cultivated for its foliage and its seed, the former of which is an important stock food, the latter a source of colseed oil. It resembles the turnip in foliage, but grows taller and lacks the turnip-like root. In America it is not grown for its seed at all, but toward the end of the 19th century became an important soiling and forage crop for sheep and beef cattle. It is usually sown after mid-summer upon any good soil, and is especially popular in cool climates because it will stand considerable cold without injury.

RAPE, a word derived from German "raffen" and old English "rap," to seize and carry away, and meaning in law the crime of having carnal knowledge of a woman without her consent and by force. This has always been regarded as one of the highest crimes, and is still punished by death in some American States; in others by long terms of imprison-

ment. In the case of a female who has reached the age of consent, and who is not an idiot, the element of force is essential to constitute the crime of rape. If consent is obtained by the use of threats which convince the woman that it would be useless to resist, it is not necessary to prove actual violence. It has long been established by court decisions in England and America that deception, as when a married woman is deceived into believing that a man not her husband is her husband, does not constitute rape. Within the past 20 years statutes have been passed in England and most of the United States raising the age of consent for girls. These laws have been of great service in protecting the young and promoting morality.

RAPE OF THE LOCK, *The*. Pope's 'Rape of the Lock' (1714), a mock-epic of 814 lines in heroic couplets, remains the most famous and perhaps the most finished example of society verse in English. The serio-comic genesis of this brilliant, fanciful and vivacious poem was the very pretty social quarrel that resulted when a certain Lord Petre had stolen a lock of the hair of a Miss Arabella Fermor. Pope's friend Caryll asked the young poet, just then becoming famous, to heal the breach by friendly ridicule. Pope consented, and published his first version of his poem in Lintot's *Miscellany* in 1712. The success of the charming trifle was so great that the poet planned a more elaborate version in the form of the mock-epics then popular in France and England. He conceived the idea of parodying the supernatural machinery of the epic by using the gnomes and sylphs of the so-called Rosicrucian philosophy instead of the classical divinities. These he very appropriately made attendant upon his heroine, and added also a scene of a game at cards and other details. The result justified the revision and elaboration. 'The Rape of the Lock' as published in 1714 at once took its place as the supreme product of the drawing-room muse.

It does not sparkle so brilliantly after the lapse of two centuries. The heroic style is out of date; the literary parody has lost its significance; the beaux and belles belong to a past age; the dainty filigree work has grown somewhat tarnished. Under all this lies a more fundamental defect: despite Pope's dedication of the poem to Miss Fermor as a tribute to her charms, it is the product of an age and a class that regarded woman as little better than a fool. Even Addison, though urbane and gracious enough, assumes this in his *Spectator* satire; Pope, embittered by his sense of the personal deformity that rendered him unattractive to women, embodies in his clever epigrams implications none too complimentary to the sex. His admiration is feigned; his satire is sincere. But such defects in the poem are counterbalanced by qualities that defy the passing of time and any change in taste and point of view. The story is admirably managed: Belinda's toilet, her trip up the Thames to Hampton Court, the game at cards, the afternoon tea, the rape of the lock itself and the ensuing battle, the anxiety and the intervention of the attendant spirits, are clearly and firmly presented. The preparation, climax and catastrophe are the work of a master craftsman. The verse, with its plenitude of epigrammatic,

often stinging, couplets, is polished to the last degree. The language shows "the most dextrous transformation of ordinary social gabble into mock heroic." Many of the epigrams are characteristic of the age that "knew how to refine shrewd sense into wit"; and Pope's *Ariel*, though of course a mere parody of Shakespeare's, is a charming poetic fancy. As a whole 'The Rape of the Lock' is the consummate satirical expression of a social phase and a masterpiece of its kind by a master artist in poetry.

MARION TUCKER.

RAPHAEL, rā'fā-ēl, William, Canadian artist: b. Berlin, Germany, 1839; d. Montreal, Canada, 16 March 1914. He studied painting at the Royal Academy, Berlin, under Wolf, Begas and others, and in 1860 settled in Montreal, where he afterward lived and worked. He painted both figures and landscapes, and in addition to his work as a painter conducted a large drawing and painting class. He was the first to introduce in Montreal drawing from casts and from life. Among his pupils was Wyatt Eaton. He was one of the original members of the Royal Canadian Academy of Art; and in 1904 he was appointed a member of the Council of Arts and Manufactures of the Province of Quebec. His works were largely acquired for private collections. Among them are 'Bonsecours Market, Montreal, in Summer and Winter'; 'Habitants attacked by Wolves'; 'The Early Bird Gets the Early Worm,' etc.

RAPHAEL SANTI, rā'fā-ēl sán'tē (called by the Italians *RAFFAELLE* and *RAFFAELLO*, but generally in his own writings and in the signing of his pictures, *RAPHAEL*), Italian painter: b. Urbino, in Umbria, 28 March 1483; d. Rome, 6 April 1520. The mountain town of Urbino was the capital of the ancient duchy of the same name, which came to an end in 1626. The castle or palace of the duke is still a building of extreme interest; and there is evidence that during the lifetime of Frederigo and Guidobaldo—who reigned during the years of Raphael's youth—the palace was one of the most remarkable museums in Italy, being crowded with works of art both of antique and of Renaissance production.

The young Raphael was allowed to devote himself to art the more readily that his father (Giovanni) was himself a painter. It seems that the family had lost property; and there is much in the record concerning Raphael to indicate the existence in his character of traditions of elegant life and that kind of sympathy which comes from ancestral cultivation. At a very early age for a student of art he entered the workshop of Perugino; his possibly earlier studies with Timoteo Viti being of little consequence to his artistic growth. It is asserted that the young man went to Siena, where Pinturicchio was at work; but this is doubtful, and it is only important because there has been so much question about the true influence which at first determined or modified Raphael's career. It was as early as 1504 that he first went to Florence, and the artists who would then have influenced him the most were Leonardo da Vinci and Michelangelo; because while the earlier Florentines would be more immediately recognised by him as painters of the ancient

and traditional manner, it is clear from his subsequent history that he was more quick than any other man would have been to adapt himself to the larger conditions of a new world of art. The first absolutely modern painting may be said to have come into existence with Leonardo da Vinci, although that great master allowed himself but little time to devote to executive work, and has left us almost nothing by which we can judge his full strength. As for Michelangelo (eight years Raphael's senior, and as precocious), his work must have revealed to Raphael the possibilities of magnificent design in which the human body is treated as the principal subject, without important assistance in the way of draperies, backgrounds or even narrative subject, as a work of art.

The earliest painting which can be ascribed to Raphael with some certainty is the *Marriage or Betrothal of the Virgin* (called 'Lo Sposalizio') at the Brera Gallery in Milan. This picture shows the Umbrian feeling, and has many resemblances to the full manner of Perugino, Raphael's master; but it is significant that no serious attempt has been made to dispute the ascription of it to Raphael himself, so great is the resemblance in the peculiar grace of its composition to the more mature works of the younger man. The most important record we have of his earliest stay in Florence, ending with his 25th year, is the *Madonna with Saints* in the National Gallery, commonly known as the 'Ansidei Madonna,' which, however, is thought to have been painted during a visit which he made to Perugia; and other *Madonnas*, such as that in the Pitti Palace, called the 'Madonna del Gran Duca,' and the 'Madonna with the Goldfinch' in the Uffizi; as well as a picture in the Louvre Museum at Paris, called 'La Belle Jardinière.' This epoch, however, was one of constant production, and there are many small paintings, only less important, than those named above, which may with considerable certainty be given to this period, namely, the years of his life from 20 to 25. It was in 1508 that he went to Rome.

It does not appear that Raphael was sent for directly by the order of Pope Julius II, but he began work there almost immediately on his arrival, and indeed the first of the famous halls in the Vatican which are covered with his paintings was completed, nearly as we see it now, as early as 1511. This room, known as the Camera della Segnatura, or Chamber of the Signature, is a hall roofed with a solid masonry vault, having one large window turned nearly to the north and lighting the room fairly well on bright days. On the west wall is the famous painting known as the 'Disputa de Sacramento,' which should properly be called in English 'The Glory or the Triumph of Religion'; and opposite this to the east is the 'School of Athens.' Over the window is the Parnassus presided over by Apollo; and opposite the window is, in the lunette, the magnificent 'Jurisprudence'; while below this and on either side of the deep niche serving as the recess of a window now condemned, are paintings having to do with the Papal authority; earthly and spiritual things. Similar paintings adorn the dado beneath the great pictures, and the vault itself is covered with work of Raphael's own hand; in fact, lovers

RAPHAEL SANTI

Raphael's painting, considered by itself and without reference to its historical importance, have always found the Camera della Segnatura the most delightful place for the study of the master's individuality. There is every reason to suppose that the greater part of the work here is due to his own touch; the employment of assistants being much less probable here than in later works.

When this first series of important wall paintings was completed Raphael was 28 years old and he had only nine years to live. During those nine years were produced the paintings in the four large rooms in the Vatican adjoining the Camera della Segnatura, and also the decorative frescoes in the Farnesina Palace, the outdoor corridors and vaulted galleries fronting the Cortile di S. Damaso in the Vatican, which are known as the Loggie di Raffaello, and also a great number of easel pictures in oil, portraits, religious pictures sent as presents to the king of France and other foreign princes, and, toward the close of his life, two pictures of peculiar importance in his history, because they have always excited so much general admiration. These are the 'Madonna di San Sisto,' now in the royal collection at Dresden, and 'The Transfiguration,' left unfinished at his death, and now in the picture gallery of the Vatican. Raphael also made some designs, or at least undertook some superintendence as architect, especially in connection with the church of Saint Peter, and as designer of several palazzi, or stately mansions, in and near Rome. The excavations going on among the ruins of Rome also excited his interest and took up much of his time. He was surrounded by assistant artists who worked with him or for him, under his general direction and also from his studies and under his immediate control. It is now impossible to discriminate between these different ways of work, except by means of the internal evidence of more or less characteristic handling in the painting. Thus it is generally agreed that the large frescoes of the battle at the Milvian bridge and the other paintings in the Stanza di Constantino are almost wholly by the hand of his assistants; while those in the Stanza dell' Incendio and in the Stanza dell' Eliodoro are, though not wholly by the hand of Raphael, his work as to their general designs, as to their composition both in mass and in color and largely his own creation. The remarkable fact concerning these and the smaller paintings is that they all, except some of those in the Constantine series, belong to that well-known family or class of works which have become familiar to all the European world, as typical pictures by the artist who is generally accepted as the first of religious painters, while at the same time his name is used by artistic reformers as a symbol of the commencement of the decline of art.

His work shows little interest in realization of incident or of action; he is regardless of the impossibilities of the Apostles in long and voluminous robes, and of men in a fishing boat much too small for them—indifferent to the contradictions of the famous picture of 'The Conflagration in the Suburb' ('Incendio del Borgo'), where flames are seen flickering among marble columns and walls of cut stone without anything to feed them; and yet this

lack of realism in his designs has never diminished his vast popularity, as the typical painter toward whose work everyone turns when there is mention of Christian religious painting. There is no better instance of the purely artistic quality obtaining full recognition in spite of the absence of those qualities which are generally considered more popular; the main reason for this is in the extraordinarily perfect composition in line and in mass: the figures filling the chosen oblong or the lunette or the circle in so many of his compositions, with absolutely faultless harmony, producing the desired result—a picture of entirely harmonious effect. As a colorist he is not one of those painters to whom glow and splendor of hue is the important thing, who deem design in color supreme, as do Correggio and the great Venetians from the time of Vivarini to that of Tiepolo; but invested his noble linear compositions with a coloring wholly agreeable, never violent, always satisfactory to the student of sentiment in art, and to the lover of noble composition—those students being more numerous in the world than the lovers of color for its own sake.

RUSSELL STURGIS.

RAPHAEL WARE. See MAJOLICA and MEZZA-MAJOLICA.

RAPHALL, Morris Jacob, American rabbi and author: b. Stockholm, Sweden, September 1798; d. New York, 23 June 1868. In 1812 after receiving rabbinical education at Copenhagen,

he went to England to study its language and literature, and after a continental tour spent three years at the University of Giessen, returning to England in 1825. In 1832 he lectured on post-Biblical history in London, in 1834 began a 'Hebrew Review and Magazine of Rabbinical Literature,' which he edited with much scholarship, was associated with D. A. De Sola in a translation of 18 treatises of the 'Mishna,' and with Messrs. De Sola and J. L. Lindenthal in a commentary on Genesis. In 1841 he was elected rabbi of the Birmingham Synagogue and in 1849 was called to the Congregation B'nai Jeshurun of New York, where he remained until his death. In 1855 he published his 'Post-Biblical History of the Jews.' In addition he wrote some learned pamphlets and was a contributor to *The Jewish Messenger*. His defense of slavery from the biblical standpoint ('The Bible View of Slavery') aroused much controversy in the early days of the Civil War.

RAPHANIA, another name for the disease called ergotism (q.v.).

RAPHIA, a genus of low African palms with oval, gigantic pinnate leaves, and fruit spikes often weighing from 200 to 300 pounds.

RAPID CITY, S. Dak., city and county-seat of Pennington County, 125 miles southwest of Pierre, on the Chicago and Northwestern, the Chicago, Milwaukee and Saint Paul and the Rapid City, Black Hills and Western railroads. The city is located in the Black Hills mining region in which are deposits of gold, tin and mica. There are granite quarries and lumber interests, foundries, a chlorination plant, leather works and flour mills. The South Dakota School of Mines is located here and there is a United States government Indian school. Pop. 3,854.

RAPID-FIRE GUNS. See **ORDNANCE**.

RAPIDAN RIVER, a small river in Virginia, rising on the southeastern slope of Blue Ridge and flowing in an easterly direction toward the Rappahannock, which it enters 10 miles above Fredericksburg.

RAPIDS. See **WATERFALL**; **CATARACTS**.

RAPIER, a sword-like weapon of two different types: (1) a light, highly tempered two-edged and finely pointed weapon, about three feet in length; a favorite weapon used with the dagger for dueling and fencing during the 16th and 17th centuries; (2) the "small-sword," a pointed weapon used during the 18th century without the dagger.

RAPIN DE THOYRAS, ră-pân dè toi-râ, Paul, French historian: b. Castres, Languedoc, 1661; d. Wesel, Duchy of Cleves, 1725. He studied at the Protestant Academy of Saumur, and was admitted an advocate in 1679. The revocation of the Edict of Nantes, however, drove him to England in 1686 and subsequently to Holland, where he entered a company of French cadets. In 1689 he followed the Prince of Orange and distinguished himself at the battle of the Boyne. In 1707 he settled at Wesel and devoted himself to historical composition. His great work, 'L'Histoire d'Angleterre' (1724), was very animated, but impartial, and contains much solid information. The style is clear, the facts are methodically arranged,

and he is always careful to cite his authorities. It embraces the period from the invasion of the Romans to the accession of William and Mary, but continuations by other pens were afterward added.

RAPP, rāp (Johann) George, German secretary, founder of the communistic society called Harmonites: b. Iptingen, Württemberg, 1 Nov. 1757; d. Economy, Pa., 7 Aug. 1847. He studied in the village school, became a linen weaver, and seems very early to have had religious doubts and visions, and dated his "complete surrender" from the year 1782. His peculiar religious ideas were so tinged with political socialism that his followers were persecuted by the German government; and in 1803 he emigrated. In the next year he founded at Harmony, near Pittsburgh, a communistic colony, where work, unity, equality and celibacy were the rule. A new colony, called New Harmony, was founded on the Wabash in Posey County, Ind., in 1815 and was sold to Robert Owen (q.v.) in 1824 when Rapp and his followers returned to Pennsylvania, founding on the Ohio River the town of Economy (q.v.). Consult Nordhoff, 'Communistic Societies of the United States' (1875); Knortz, 'Die Christlich-kommunistische Kolonie der Rappisten' (1892).

RAPP, Jean, COUNT OF, French general: b. Colmar, Alsace, 27 April 1772; d. near Lorrach, Baden, 8 Nov. 1821. In 1788 he entered the military service, accompanied Desaix during the campaigns in Germany and Egypt, and after Desaix had fallen at Marengo became aide to Bonaparte. On the breaking out of the war against Austria, in 1805, he accompanied Napoleon, and after the battle of Austerlitz, where he threw the Russian guards into confusion by a bold attack with his cavalry, he was made brigadier-general. For distinguished service done in 1809 he was created a count of the empire, and in 1811 received the cross of grand officer of the Legion of Honor. He was seven years commander of Dantzic, which he defended after the retreat of the French army from Russia, till 1814, during a severe siege of nearly a year, in which he displayed great talent and brilliant courage, and not till all means of defense were exhausted and he was compelled by famine did he capitulate. Returning to France in 1814 he was received with distinction by Louis XVIII, and in March 1815 was sent against Napoleon. But when the defection of the whole army rendered all resistance impossible, Rapp also went over to Napoleon, who made him commander of the army of the Rhine. When Louis XVIII returned a second time to Paris, Rapp was pardoned, and retained the command of the 5th division, granted him by Napoleon, till the army was disbanded. After his death appeared the interesting 'Mémoires du Général Rapp, écrits par lui-même' (1823). Consult Spach, 'Le Général Rapp' (1856).

RAPPAHANNOCK, răp-a-hăn'ók, a river of Virginia, formed by several small streams which have their rise in the Blue Ridge. It flows southeast into Chesapeake Bay, which it enters about 25 miles below the Potomac. It is about 250 miles long and is navigable over 90 miles from its mouth. The upper part of its course is through a mountainous country, where it is

a swiftly flowing stream with many rapids and low falls. At Fredericksburg (q.v.) is a fall which furnishes extensive water power. From Fredericksburg the river becomes a tidal stream, and the broad, long estuary which enters the bay is navigable for the largest steamers. The name of the Rappahannock is associated with many of the events of the Civil War. See **BOUNDARIES OF THE UNITED STATES**.

RAPPAHANNOCK STATION, Battle of. In the fore part of October 1863 General Lee maneuvered the Army of the Potomac, under General Meade, from the Rappahannock River back to Centreville. Meade resumed the offensive 19 October, and in several encounters pressed Lee back to the Rappahannock, Lee crossing to the south side of the river and disposing his army on both sides of the Orange and Alexandria Railroad, Ewell's corps on the right and A. P. Hill's on the left, with cavalry on both flanks. A part of Ewell's corps was left on the north side of the river at Rappahannock Station, in an intrenched position covering the pontoon-bridge, the railroad bridge having been destroyed. The position was first held by General Hays' brigade and four guns, to which was subsequently added General Hoke's brigade, under Col. A. C. Goodwin. The whole force numbered about 2,000 men. Lee had destroyed the railroad from Bristoe Station to the Rappahannock, a distance of more than 20 miles, and this had to be rebuilt before Meade could follow to the river. It was completed as far as Warrenton Junction on 2 November; supplies were brought up; and on the morning of the 7th Meade advanced to cross the Rappahannock. General French, with the left wing of the army, moved upon Kelley's Ford, five miles below Rappahannock Station, and forced a passage of the river (see **KELLY'S FORD, ENGAGEMENTS AT**), while the Fifth and Sixth corps, under command of General Sedgwick, moved along the line of the railroad, forming line about midday within one and a half miles of Rappahannock Station, the right of the Fifth corps and the left of the Sixth on the railroad. Skirmishers were thrown forward and the Confederate position reconnoitered, and as soon as it could be ascertained a plan of attack was formed. The works to be carried consisted of two redoubts, connected by a chain of rifle-pits, and a further line of rifle-pits ran from the left redoubt to the river and some distance along it. The Fifth corps was to gain the river bank on the left and the Sixth on the right, in order to establish artillery on a range of high ground in front of the works and drive the men from them. The river bank was gained both on the right and left, artillery put in position and the works shelled, but at dusk no impression had been made, the Confederate guns had not been silenced, nor had the infantry been driven from the works. General Russell, temporarily commanding Wright's division of the Sixth corps, said that he could carry the works by assault, and he was ordered to do it. It was now after dusk; artillery fire was kept up; Russell led parts of Ellmaker's and Upton's brigades, in all 2,117 men, and, under a heavy fire of musketry and canister, went over the works in a very few minutes, capturing 1,303 officers and men, the four guns, 1,225 stands of arms and seven battle flags. A part of the Fifth corps on

the left joined in the assault. General Wright says in his report that this was the first case during the war of an intrenched position being carried on the first assault, and one of General Lee's biographers writes that it was the saddest chapter in the history of the Army of Northern Virginia. General Hays, with nearly 300 of his men and about 130 of Hoke's, escaped. The Union loss was 413 killed and wounded and six missing. General Lee reports his loss as 6 killed, 39 wounded and 1,629 captured or missing, some of the missing being probably killed or wounded. Lee now abandoned his design of attacking General French, who had crossed at Kelly's Ford, burned the end of the pontoon-bridge remaining in his possession, the north end of it having been captured by Russell, and fell back during the night to Mountain Run. General Meade crossed the remainder of his army over the Rappahannock on the 8th and moved to Brandy Station, and Lee crossed to the south side of the Rapidan. Consult 'Official Records' (Vol. XXVI); Humphreys, 'From Gettysburg to the Rapidan'; the Century Company's 'Battles and Leaders of the Civil War' (Vol. IV).

E. A. CARMAN.

RAPPISTS. See **HARMONISTS**.

RAPPROCHEMENT (Fr., reconciliation), in diplomatic language, signifies a reapproachment or reconciliation between nations or governments after a period of enmity.

RAPTORES, an old name in classification, variously limited, for the predatory birds. See **BIRDS OF PREY**.

RARATONGA, *rā-rā-tōng-gā*, or **RAROTONGA**, an island in the South Pacific Ocean, belonging to the group of Cook Islands (q.v.).

RAREY, John S., American horse tamer; b. Franklin County, Ohio, 1828; d. Cleveland, Ohio, 4 Oct. 1866. In early life he showed a marked fondness for horses and skill in their management, which he later developed by study and close association with them. In 1856 he went to Texas to further his knowledge and upon his return to Ohio engaged in startling exhibitions of his skill; later he exhibited all over the United States. In training or taming the horse his methods were always prompted by a humane spirit, the use of the lash not being resorted to unless in extreme cases. In 1861 he visited England, Russia and other European countries, where his mastery over the wildest steeds amazed and delighted his vast audiences.

RARITAN, a river in New Jersey, the headwaters of which are in the northern part of the State. It enters Lower New York Bay at South Amboy, through Raritan Bay. The latter is really the broad mouth of the Raritan River. The river is navigable to Brunswick Landing, about two miles above New Brunswick.

RASCAL LEAF-CRUMPLER, the leaf-folding caterpillar of a phycitid moth (*Mineola indiginella*) injurious to many American fruit-trees, as the apple, cherry, plum (qq.v.), etc. See **MORR**.

RASH, an eruption on the skin, characterized by reddening without large pustules. The commonest rashes are those of the specific

fevers, the crimson rash of measles, the scarlet rash of scarlet fever, the rose-spots of typhoid fever, etc. But there are also numerous rashes due to disordered states of the body, and apart altogether from any infectious disease; such are nettle-rash and the like.

RASHI, *rā'shē*, properly **RABBI SALOMON-BEN-ISAAK**, sometimes erroneously called **JARCHI**, the most famous of French rabbins: b. Troyes, about 1040; d. 1105. Entering the Jewish school in Worms he made astonishing progress in ancient languages, philosophy, medicine and astronomy. His skill in explaining the Holy Scriptures and the Talmud was so remarkable that his contemporaries honored him with the titles of interpreter of the law and prince of interpreters. To satisfy his longings after knowledge he undertook an extensive tour through Italy, Greece, Palestine, Egypt, Persia and Germany, where he was particular in visiting the towns which possessed learned Jewish schools. The literary treasures thus collected he introduced into his writings, which were received at the time with the greatest enthusiasm, and are still held in high estimation. His Hebrew Bible commentary is still standard, also his famous commentary on the Pentateuch. He also wrote commentaries on the prophets; but his 23 treatises on the Talmud comprise the work that gave him his lasting fame. He wrote much in Old French, and his books are to-day the final authority as to the word forms then in use. Consult Zunz, 'Zeitschrift für die Wissenschaft des Judenthums' (1822); Graetz, 'History of the Jews' (Trans., Philadelphia 1891); Morris Liber (in 'The Jewish Ency.', New York 1905).

RASK, *räsk*, **Rasmus Christian**, Danish scholar: b. Brendekilde, island of Funen, 22 Nov. 1787; d. Copenhagen, 14 Nov. 1832. He studied at the University of Copenhagen, undertook a journey to Sweden and Russia, to increase his acquaintance with the northern languages; and in 1808, after a two years' stay in Iceland became assistant in the academical library of Copenhagen. His fame as a linguist is founded upon such works as 'An Introduction to the Knowledge of the Icelandic or Old Norse Tongue' (1811); an edition of Björnson Haldorsen's 'Icelandic Dictionary' (1817); 'Instruction in the Anglo-Saxon Tongue'; 'Researches as to the Origin of the Old Norse or Icelandic,' and a series of grammars in nine languages. In 1822 he was appointed professor of literary history at the University of Copenhagen, and subsequently professor of Oriental languages and librarian to the university. During this period he published, among other works, 'Instruction in the Friesland Tongue'; 'On the Antiquity and Genuineness of the Zendavesta.' Consult 'Samlede Afhandlinger' (3 vols., Copenhagen 1834-38), these being his collected essays.

RASKOLNIKS, *raș-kôl'nyiks*, or **RASCOLNICIANS**, the name applied collectively to all the dissenters from the orthodox church of Russia, the Greek-Eastern Church. The schism, or *raskol*, was affected at two different times principally; first during the 17th century upon the occasion of the revision of the Testaments by Patriarch Nikou (1652-58) at Moscow; and upon the further revision and the usurpation of secular powers by Peter the

Great (1689-1725). On both these occasions great bodies of Raskolniks, refusing to comply with the reforms instituted, left the Church and set up their own religious communities. The general characteristic of all the Raskolniks is conservatism. Their accessions have been due to the desire to cling to their old customs and beliefs.

The Raskolniks are of two great classes, each of which is subdivided with endless schisms and dissenting sects, more or less antagonistic to each other. The Popovtzi, those who have priests, *pops*, in Russian; and the Bezpopovtzi, or those who have no priests. Of these the Bezpopovtzi are the more numerous, the most aggressive and the least conservative.

The Popovtzi have not changed from the beliefs of their old Church. They are, for the most, inoffensive and tolerant, and have latterly been treated by the state with less severity than before. A certain measure of civic rights was also granted them, together with liberty of religious services.

The Bezpopovtzi were much more inimical to the State and the Church, as these were constituted prior to the Revolution of 1917. They believe that the present age is one of the anti-Christ, that the authorities to-day, both temporal and spiritual, are his servants and that, therefore, it would be sin to recognize their authority. Some of the principal sects of the Bezpopovtzi are: Duokhobors (q.v.), who in some respects resemble the early Quakers; the Vozdykhantzi, who hold that the world at present is under the reign of the Holy Ghost, whom they worship by prayers and sighing; the Philipppines, who observe only two sacraments, the Lord's Supper and Baptism; the Stranniki, who believe the promises of the Lord concerning the Church are already fulfilled and that we are living in the first era of the resurrection; the Molokane and the Obschie (the latter being communists), who reject all external rites; and the anarchistic Khlisti and Skoptzi. The Khlisti are ascetics and practise many fanatical rites under the direction of their prophets and prophetesses, one being that of bodily scourge. The Skoptzi carry the beliefs of the Khlisti to an even greater extreme, mutilating their bodies in horrible manner in the frenzy of their rites. The Khlisti and Skoptzi were treated as criminals and transported to Siberia by the government under the old régime; other sects of the Bezpopovtzi were denied many of the civil rights enjoyed by the Popovtzi, were closely watched by the police and were much feared by the government.

The number of Raskolniks in Russia has been variously estimated as from 5,000,000 to 15,000,000.

RASMUSSEN, *räs'müs'sën*, **Knud Johan Victor**, Danish Arctic explorer: b. Jakobshavn, Greenland, 7 June 1879. He was educated at the University of Copenhagen, visited Lapland in 1901 and in 1902-04 he was a member of the Mylius-Ericksen expedition to Greenland. In 1905-08, 1909 and 1910 he was engaged in ethnological expeditions to Greenland, and in 1912-14 he headed an expedition for the recovery of the Mylius-Ericksen records, which, however, were found by Mikkelsen. His trip resulted in the discovery of a considerable area of ice-free land and proved the non-ex-

istence of the Peary Channel. Rasmussen has made extensive reports of his explorations and ethnological researches. Author of 'Lapland' (1907); 'The People of the Polar North' (1908); 'Avangarnisalessarutit' (1909); Rasmussen *sermerssuakut Tunullarnilerssarutit'* (1916), etc.

RASORES, *ra-sô'rez*, group of birds and "scratchers," so named from their habit of scratching the ground for food, represented by such forms as the fowls, partridges, grouse, pigeons, etc., which were long ago assigned to various natural orders and families. Illiger grouped them in two sub-orders, the *Columbacei* and the *Gallinacei*. Later they were made orders of Carinate birds; the former (*Columbæ*) including the pigeons, and the latter (*Gallinæ*) with eight families: *Cracidae*, *Opisthocomidae*, *Phasianidae*, *Meleagridæ*, *Tetraonidae*, *Pterodidae*, *Turuidæ* and *Megapodidae*. The Rasores of Vigors consist of the families *Columbidae*, *Phasianidae*, *Tetraonidae*, *Struthionidae* and *Cracidae*; those of Swainson, of *Pavonidae*, *Tetraonidae*, *Struthionidae*, *Columbidae* and *Megapodidae*; and those of Gray, of *Cracidae*, *Phasianidae*, *Tetraonidae*, *Chionidae* and *Tivamide*.

RASPAIL, *ras-pä'y'*, François Vincent, French politician and scientist: b. Carpentras, 29 Jan. 1794; d. Arcueil, 7 Jan. 1878. He went in 1816 to Paris. He took part in the July Revolution of 1830, and later established a journal, *Le Réformateur*, which in 1834 was suppressed by the government, while in 1835 its editor was condemned to a six months' imprisonment. On 24 Feb. 1848, at the head of a mob, he penetrated to the council chamber of the provisional government, which he compelled forthwith to proclaim the republic. He then founded *L'Ami du Peuple*, later called *Démocratie Pacifique*, in which he proclaimed Jacobin principles. On 15 May he was a leader of the invaders of the Palais Bourbon and the hall of the National Assembly; for this he was condemned to six years in prison, but in 1855 the sentence was commuted to banishment. He lived in Brussels, but returned to France under the amnesty of 1859, was elected to the Corps Législatif in 1869, retired to private life during the Commune, and from 1876 was a member of the Chamber of Deputies. From 1824 till 1830 he contributed many scientific articles, especially on chemistry, to the 'Annals of the Natural Sciences' and other works, and by many has been considered the creator of the system of organic chemistry. Among his works were 'Annales des Sciences d'Observation' (1829-30); 'Recherches Chimiques et Physiques sur le Développement des Tissus Végétaux' (1827); 'Cours Élémentaire d'Agriculture et d'Économie Rurale' (1831); 'Système Nouveau de Physiologie Végétale et de Botanique' (1836); 'Système de Chimie Organique' (1837); 'Histoire Naturelle des Ammonites' (1842); 'Nouvelles Études Scientifiques et Philologiques' (1865); 'Réformes Sociales' (1872). Consult Marchal, 'Biographie de F. V. Raspail' (1848); Quérard, 'La France Littéraire'; 'Nouvelle Biographie Générale.'

RASPBERRY, a general name for those shrubs of the genus *Rubus*, whose fruits separate from the receptacle upon attaining maturity. They are natives of the north tem-

perate zone and are especially numerous in Europe and America. They are characterized by their perennial underground parts, usually biennial spiny stems which with few exceptions bear fruit the second season and then die. A few cultivated varieties, notably Saint Regis and Gault, bear some fruit on the young stems the same season as these develop. Several species are valued for ornamental purposes but the three following are the most important because of their edible fruits, for which the plants, except the first which is unsuited to American climatic conditions, are widely cultivated, especially in the United States and Canada. The European raspberry (*R. idæus*), which has been cultivated in Europe for several centuries, was among the earliest European fruits introduced into America, but it has not made an equal headway with the next species because it has a very extended period of ripening, and is more adapted to the amateur than to the commercial berry-grower. Its fruits, either red or yellow, are of the best quality, but the plants are considered somewhat tender in northern climates. The American red raspberry (*R. strigosus*) resembles the preceding species in habit and color of fruit, but is rather inferior in quality. This defect, however, is offset by its hardness, ready adaptability to many conditions and its prolific and rapid production of fruit. The black raspberry or blackcap (*R. occidentalis*) is the most important species of its genus, since it is hardy, productive, adaptable to many soils and conditions, and its fruits, being firm, are useful for shipping considerable distances or for evaporating as well as for canning and eating fresh. It was introduced into cultivation in 1832, since when several hundred varieties have been offered for sale.

The red raspberries are propagated by means of suckers, or root-cuttings. The former may appear at any time throughout the growing season; the latter may be made by thrusting a spade deeply into the ground around well-established plants and thus severing the roots, each piece of which will produce a new plant. With new or scarce varieties the plants are often dug up, the roots cut in small pieces and rooted in greenhouses, hot beds and cold frames. In the field the plants are usually set not less than 3 by 5 feet apart, the plants being allowed to form a continuous hedge row, cultivation being given only one way. Except while the plantations are under three years old it is impossible with most varieties to cultivate in two directions (checks) because the plants develop suckers abundantly.

The black raspberry does not produce suckers, except at the crown, but the tips of the canes bend over until they reach the ground and become covered and develop roots. Other buds near the end may develop short stems which also become rooted. These "tips" are severed for planting, sometimes in autumn but usually in spring, and are set somewhat farther apart than the red varieties, usually 5 by 5 or 6 by 6 feet part. They are generally cultivated in two directions because of this "killing" habit. There is a hybrid group of raspberries which propagate by both tips and suckers or root cuttings, usually by the latter. They are supposed to be derived from the black and the

American red species, but since they are common in the wild state and are fairly stable, they are often grouped under the species name, *R. neglectus*. Several varieties have been widely cultivated. Their fruit ranges from purple, through reds to yellow.

Raspberries succeed best upon deep, moist, but well-drained loamy soils; the blacks upon the heavier and the reds upon the lighter. The more retentive of moisture the soil is the better, since the fruit ripens at a time when water is often scarce. Hence the addition of humus is usually desirable. It may be most easily obtained in the form of stable manure and green manures, such as clover grown at least one year before planting to raspberries. The ground should be plowed as deeply as possible without turning up the subsoil, and after harrowing, the plants set. Clean cultivation both ways is usually practised until midsummer when a cover crop of crimson clover or some shallower rooting plant is sown to be turned under the following spring. Sometimes, however, other crops, such as peas, beans, tomatoes and other shallow rooting vegetables which are not tall, are grown between the rows for one or perhaps two years. Wood ashes, muriate of potash, superphosphates and ground bone are favorite sources of potash and phosphoric acid. With adequate tillage during the summer, spring plowing may be avoided.

The pruning of the red varieties consists in pinching back the shoots during the first season, allowing only about five canes to grow in each stool in after years, avoiding the pinching of shoots unless the soil is very strong and the growth rampant, and cutting out the old canes as soon as they have fruited. The pruning of the blackcaps consists in pinching off the tips each year as soon as they have reached a height of about 20 inches. This tends to make the canes stocky and self-supporting. Spring pruning consists in shortening in the branches to about 18 inches and removing pruned and excess shoots. This latter amounts to thinning and should be carefully done.

For market the fruit should never be picked until after the dew has dried and should be shipped to market in small packages. Red raspberries are usually marketed in pint baskets. Black raspberries, especially for canning, are often gathered by jarring the ripe fruits into aprons with boxes attached, the fruit being passed through a fanning mill to blow away the leaves, etc. Generally, however, the picking is done by hand with red raspberries and with both kinds for the best markets.

Among the numerous insects which feed upon the raspberry are two species of cane-boring beetles, *Agrilus ruficollis* and *Oberia bimaculata*; wilting of the canes is usually the first indication of their presence, cutting and burning the injured ones is the only remedy recommended. The striped tree-cricket (*Ecanthus nigricornis*) often lays its eggs in the stems, but is considered to be a beneficial insect otherwise, since its food consists largely of plant-lice. Several caterpillars and other foliage-chewing insects, such as the raspberry saw-fly (*Monophadnus rubi*), occasionally prove troublesome, and some of the stink-bugs reveal their presence by their disagreeable flavor when inadvertently eaten. General remedies have been recommended for these insects. (See

INSECTICIDE). Several so-called plant diseases have been reported upon the raspberry. The orange rust has never been successfully combated. It attacks weak plants. Digging out and burning the plants attacked by it is the only remedy. It should be done as soon as the disease is discovered in May. Anthracnose has been held in check by spraying with Bordeaux mixture. See FUNGICIDE.

Consult Bailey, 'Standard Cyclopaedia Horticulture' (New York 1914-17); Card, 'Bush-Fruits' (New York, 2d ed., 1917); books on insects listed under INSECTICIDE, and numerous bulletins of Agricultural Experiment Stations and of the United States Department of Agriculture.

RASPE, ras'pe, Rudolph Eric, German mineralogist and author: b. Hanover, 1737; d. Muckcross, Donegal, Ireland, 1794. In 1767 he was made professor in the Collegium Carolinum of Cassel, and curator of the Landgrave's museum of coins and antiquities. He published at this time papers on mineralogy and geology. In 1775 he went to England, where he was variously employed, generally as a mining expert. He published in 1785 'Baron Münchhausen's Narrative of his Marvelous Travels and Campaigns in Russia,' founded in part on the hunting stories of one Baron von Münchhausen, of Hanover. His work appears as chapters ii-vi of the later Münchhausen (q.v.). Among his other writings, apart from his works on mineralogy, may be noted 'A Descriptive Catalogue of a General Collection of Engraved Stones' (1791) and several philosophical stories. See ADVENTURES OF BARON MÜNCHHAUSEN.

RASPUTIN, ra'spoo-tën', from the Russian word rasputny, dissolute, profligate, libertine, licentious: an opprobrious nickname conferred upon a notorious Russian monk named Gregor Novikh (q.v.).

RASSAM, rās-sām', Hormuzd, Turkish archaeologist: b. Mosul, Asiatic Turkey, 1826; d. Brighton, England, 16 Sept. 1910. Having formed the acquaintance of Layard (q.v.) in 1845 when the latter was beginning his explorations of Nineveh, Rassam accompanied him on his return to London and entered Oxford University, after which he went with Layard on several archaeological expeditions. In 1851 Rassam, upon commission from the British Museum, collected for that institution a number of specimens of Assyrian art, particularly a series of sculptures representing the lion chase. In 1864 the British government dispatched him on a mission to Abyssinia to secure from King Theodore the release of their consul, Mr. Cameron, and others held prisoners; but he was himself taken prisoner and held until the defeat of Theodore's army by Sir R. Napier in 1868. After 1876 he resumed his collections for the British Museum, the most notable of which were the bronze gates of Balawat, dating from Shalmanezar II, 858-824 B.C., and the "Abu-Habba tablet," from the temple of the sun-god in Sippar, recording the restoration of the temple by Nabu-apal-iddin. The British Museum was also enriched by his discovery of 5,000 tablets representing, probably, the library of an ancient Babylonish king. Rassam published a 'Narrative of the British Mission to Theodore' (1869); 'Asshur and the Land of Nimrod'

(1697); 'The Garden of Eden and Biblical Sages,' and 'Biblical Lands.'

RASSE, *räs*, a small arboreal civet (*Viverricula malaccensis*), which is widely distributed in southeastern Asia and the Malayan islands, and long ago became naturalized in Madagascar. It is slender, agile in tree-climbing, has no erectile mane and lives in holes in rocky and brushy districts. In confinement it is easily tamed and feeds on small animals, which it catches with cat-like dexterity. Hence it is often kept in houses in the East as a rat-ter, and also for the sake of its civet, which is artificially removed from the glands. It is a handsome little animal of a yellowish or brownish gray color, with longitudinal bands on the back and regular spots on the side; tail 16-17 inches long with eight or nine complete dark rings; length of body and head about 24 inches; known, zoologically, as the lesser-civet. Consult Blanford, Jerdon, Tennent and other authorities on Oriental zoology.

RASSELAS, the name usually given to a moral story with an Oriental setting written by the famous lexicographer and essayist, Dr. Samuel Johnson, and published in the spring of 1759, in two volumes, under the title of 'The Prince of Abyssinia: A Tale.' It reached a second edition the same year, and has since been often reprinted and translated, maintaining its rank as a notable if somewhat old-fashioned English classic. There is uncertainty as to just when and why and in how short a space of time it was written, but it seems clear that Johnson composed it rapidly at the period of his mother's death in January 1759, and that he probably used some of the money it brought him for filial purposes connected with that event.

Scholars have exercised themselves over the sources and the materials of the story, and have shown that Johnson did not invent his happy valley, his Abyssinian paradise; but they have taken away none of the credit due him for selecting an impressive theme—the vain search of youth after happiness—and for treating it with adequate weight of thought, soundness of feeling and dignity of style. The book plainly belongs with the grave, solid, somewhat magniloquent essays of his middle period rather than with the less stilted biographies of his old age, and it holds by his early years in owing something to his translation of the French version of Lobo's 'Voyage to Abyssinia.' Everyone of its 49 short chapters, however little calculated to arouse the interest of the experienced reader of modern novels, is thoroughly representative of Johnson himself—of his sturdy morality, his common sense, his wide knowledge of men and books, his sombre but far from cowardly and depressing views of life.

The plot is simple in the extreme. Rasselas, shut up in a beautiful valley, "till the order of succession should call him to the throne," grows weary of the factitious entertainments of the place, and after much brooding escapes with his sister Nekayah, her attendant Pekuah and his poet-friend Imlac. They are to see the world and search for happiness, but after some sojourn in Egypt, where they frequent various classes of society and undergo a few mild adventures, they perceive

the futility of their search and abruptly return to Abyssinia. That the plot should be so simple, that local color should be almost nonexistent, that episodic elements, e.g., the story of Imlac and that of the mad astronomer, should abound, is not surprising when one considers what didactic purposes the Oriental tale of 18th century western Europe was intended to serve and remembers that Johnson was a moralist and essayist, not a novelist. What does surprise is that with so little of incident, with no love-making, with few endeavors to charm the fancy, with but slight recognition of the claims of sentiment, 'Rasselas' is none the less a story that deserves its fame. It does this, not so much because it is, like 'Candide,' but in a very different way, an effective protest against shallow optimism, whether of deist or of "hustler," but because it contains not a little of the courageous philosophy of life which a great, unique personality had formed for himself at the height of a literary career full of moving vicissitudes. Consult the editions of G. Birkbeck Hill and of O. F. Emerson.

WILLIAM P. TRENT.

RASTATT, *räs'tät*, or **RASTADT**, a town of Baden, Germany, on the river Murg, about four miles from the Rhine and about 15 miles southwest of Karlsruhe. It was formerly a fortress of the first rank but in 1892 the fortifications were dismantled. The town has manufactures of lace, tobacco and cigars. Pop. about 15,196. Rastatt was the scene of two diplomatic congresses in the 18th century. The first congress of Rastatt met in 1713 to arrange terms of peace between the emperor and France, then still engaged in the war of the Spanish Succession. Peace was concluded 7 March 1714. In accordance with the terms of the treaty, signed by Marshal Villars and Prince Eugene, France gave up possession of the towns of Kehl, Freiburg and Breisach, and the electors of Cologne and Bavaria were reinstated in power. The terms of the Treaty of Utrecht (q.v.) were ratified. The second congress of Rastatt met in 1797 for the purpose of terminating hostilities between France and the empire. After negotiations had been prolonged for more than a year, war broke out again between France and the allies and the congress suspended its sessions (April 1799). As the French representatives, Roberjot, Bonnier and Debry left the city on the evening of 28 April they were set upon by a company of hussars wearing the Austrian uniform and the first two were murdered and the third sabred and left for dead in a ditch. The papers of the legation were carried off, but no other spoil was taken. This violation of the law of nations aroused the indignation and horror of all Europe. Many attempts have been made to fix the responsibility for the deed. Some have ascribed the crime to the Austrian government which was desirous of obtaining certain papers in the possession of the ambassadors; others maintain that the murderers were French émigrés, while others still assert that the act was instigated by Napoleon and other leaders of the War party in France for the purpose of exasperating the French people against Austria. In 1849 the town again became conspicuous as the stronghold of the Baden revolutionists.

RAT, any of several large rodents of the mouse family (see *Mouse*), especially two species of "house-rats" now habituated to civilization in all parts of the world. The black rat (*Mus rattus*) is of light and slender build, about seven inches in length, usually of a bluish black color, but sometimes grayish, and has quite large, thin ears. The brown rat (*M. decumanus*) or Norway rat, as it is often inappropriately styled, is much heavier and larger, with short, rounded ears and a dull brown color. Both species are believed to be natives of China but the black rat was abundant in Europe at least as early as the 13th century. The brown rat migrated from western China, entering Russia in great numbers in 1727, and from there quickly spreading over Europe, which was fully occupied by it by the middle of the 18th century. By its greater fecundity and ferocity it quickly overcame the black rat, which it has now replaced in most parts. It infested ships and by this means has been carried to all parts of the world. Its wonderful capacity for increase (from 20 to 50 annually), its boldness, tough, elastic constitution and adaptable nature, make it everywhere dominant, and its omnivorous habits, voracity and destructiveness frequently lead it to become a source of great annoyance, loss and disease about human habitations. The ferocity of this species when brought to bay is well known; and when driven by hunger it is so ravenous that neglected babies have been known to be killed and eaten by them, and a few cases are recorded where even able-bodied men have suffered a like fate when attacked by hordes of rats. They are also agents in the spread of disease, particularly bubonic plague and trichinosis. Against their many faults may be set the solitary virtue that they serve a useful purpose as scavengers in the city sewers, etc. The albino and black and white pied rats sold for pets by bird dealers are derived from the black rat, which has a far milder disposition. The rats of the United States include the black and brown of Norway, above described; the roof, or white-bellied (*M. tectorum*) of the Southern States, named from its preference for thatched roofs for its abode; the Florida (*neotorus floridana*) a habitat of the Gulf States, common to wild places and swamps, and frequently nesting in trees; the Cotton (*Sigmodon hispidus*), named from its use of cotton in forming its nest; and the Rocky Mountain, which is destructive to the trappings and stores of campers. Rat skins make fine leather for gloves.

RAT-KANGAROO. See *KANGAROO*.

RAT PORTAGE. See *KENORA*.

RAT-TAIL, one of the pelagic, cod-like fishes of the genus *Macrourus*, specifically *Macrourus bairdi* of the coast-waters of the eastern United States. The body terminates in a long, compressed, tapering tail, covered with spiny, keeled or straited scales. About 40 species are known.

RATA, any of several New Zealand trees of an Australian group of the myrtle family which includes the local ironwoods. Foremost among them is *Metrosideros robusta*, a tall strong tree, of very hard wood, used by the natives for making their war-clubs and by the colonists in cabinet-work and in shipbuilding.

Another species (*M. florida*) is a huge climber. These trees have very showy flowers, usually red, and characterized by many long erect stamens; and several species of the genus are cultivated as ornamental shrubs, and have been acclimatized in other parts of the world. One (*M. tomentosa*) is known in New Zealand as "fire-tree."

RATAFIA, *rât-â-fê-â*, generic name of a series of cordials, prepared usually by mixing an alcoholic liquor with the juice of some fruit or some flavoring material and sugar or syrup. The name is of French origin, and is said to have been given in consequence of the former habit of preparing a choice drink to be used at the ceremony of ratifying a treaty. A favorite flavoring is the almond—hence, bitter almonds, as well as cherry, peach, apricot, plum and other similar kernels, are much used; but many other flavors are also used, as orange flowers, gooseberries, raspberries, aniseed, chocolate, black currants, etc.

RATANY, or *RHATANY*. See *RATTANY*.

RATCHFORD, Michael D., American labor leader: b. Clare, Ireland, August 1860. He came to the United States with his parents in 1872, settling in Stark County, Ohio, and entered the coal mines soon afterward, studying in the evening schools. He became an active trade unionist in 1880, was elected president of the Massillon, Ohio, miners in 1890 and continued active in labor organization, serving as president of the United Mine Workers of America in 1897-98. During his presidency of that organization he succeeded in gaining the eight-hour day in bituminous coal fields and secured an annual wage contract between mine workers and operators. He was a member of the National Industrial Commission in 1898-1900; served as commissioner of labor statistics of Ohio in 1900-08; was commissioner of the Ohio Coal Operators in 1909-12, and since 1913 has been commissioner of the Illinois Coal Operators' Association.

RATEL, a South African badger (*Mellivora capensis*), rather larger than the common European or American badger, which lives in burrows in open districts. It differs from the Indian honey-badger (q.v.) mainly in the presence of a distinct white line along its sides, from the nose to the hocks, separating the black underparts from the blanket-like gray of the back. It is easily tamed, and is amusingly active in confinement, continually running about its cage and turning odd somersaults to attract attention of spectators, from which it seems to derive great pleasure.

RATHBONE SISTERS, Order of. See *ORDERS, RELIGIOUS*.

RATHBUN, Richard, American naturalist: b. Buffalo, N. Y., 25 Jan. 1852. He was educated at Cornell and at the University of Indiana. He was assistant geologist of the Geological Commission of Brazil in 1875-78, and assistant in geology at Yale in 1879-80. Since 1880 he has been curator of the United States National Museum. He was scientific assistant on the United States Fish Commission in 1878-96, being in charge of the scientific inquiry after 1887; and in 1892-96 he was United States representative on a joint commission with Great Britain for the purpose of

preserving the fisheries in the waters contiguous to the United States and Canada. He has been assistant secretary of the Smithsonian Institution since 1897 and in charge of the United States National Museum since 1899. He has contributed extensively to government and other publications.

RATICHIOUS, rä-tik'i-üs. See **RATKE**, **WOLFGANG**.

RATIFICATION, in law, the confirmation, sanction or approval given by a person who has arrived at his majority to acts done by him during his minority. It has the effect of giving validity to such acts as would be otherwise voidable. "An act performed by one for another, is adopted as his own act when by him ratified. Ratifications are either expressed or implied. The former are made in express and direct terms of assent; the latter are such as the law permits for the acts of the principals."

In *Scotch law* the acknowledgment by a married woman, apart from her husband and before a justice of the peace, that a deed executed by her is voluntary, and with full knowledge of its legal effect. In this sense the term corresponds to what is technically called in England and the United States an "acknowledgment" by a married woman. In American political life the term is applied to a popular endorsement of an act by party leaders, as a nomination for public office. The term is also synonymous with "confirmation," as when a verbal, telegraph or telephone agreement is confirmed by a signed evidence from the parties in interest.

RATIO (from the Latin *ratio*, meaning reckoning, calculation), in mathematics, the measure of the relation which one quantity bears to another of the same kind; that is, the number of times that one quantity contains another regarded as a standard. This is found by dividing the one by the other. The quotient or ratio thus obtained is the proper measure of the relation of the two quantities. Some mathematicians define the ratio of one quantity to another as the quotient of the first quantity divided by the second, and others define it as the quotient of the second quantity divided by the first. The operation of finding a ratio is purely numerical, and the resulting ratio is consequently an abstract number. Ratios are known as *prime* or *ultimate*, according as the ratio of the variable quantities is receding from or approaching to the ratio of the constant quantities. Proportion is the relation of equality subsisting between two ratios. See **MATHEMATICS**; **PROPORTION**.

RATION, in the army and navy, is the allowance of provisions given to each officer, non-commissioned officer, soldier and sailor. In the American army the ordinary ration is commonly supplemented by additional articles bought with what is known as "the company fund," money derived from certain allowances made to the soldiers. The American troops and sailors are as well fed as any in the world, whether in camp or war. The rations have varied with the time and place. A standard United States garrison ration includes 20 ounces beef, 18 flour, 2.4 beans, 20 potatoes, 2.8 prunes, 1.12 coffee, 2 sugar, 0.5 canned milk, 0.5 butter, 0.6 lard and minute portions of salt, pepper and vinegar. For a field ration bacon

usually takes the place of beef, and the bread may be reduced with an increase of canned beans, tomatoes, etc. A forage ration for a horse is 12 pounds oats, 14 of hay; the mule being lighter is fed 9 pounds of oats, but the same quantity of hay. During the World War bakeries were maintained in the army to supply fresh field bread whenever possible. The cost of the United States army rations has advanced steadily, being 13.18 cents in 1890, 14.42 in 1895, 16.97 in 1900, 16.18 in 1905, 21.44 in 1910, 25.32 in 1915, 26.81 in 1916 and 32 in 1917. British army rations are nearly identical with the American; the German is less expensive, they introducing considerable rice, zwiebach, etc.

RATIONALISM, in its more general significance, denotes a tendency or attitude of thought, either on the part of an individual or an age, to demand that prevailing beliefs, customs and institutions shall be subjected to critical examination, and be required to justify themselves before the court of reason. In its more specific sense, the term refers to the doctrines of a particular school of philosophical thinkers, which flourished mainly in France and Germany during the 17th and 18th centuries and which regarded reason as the only source of certain knowledge and the only test of truth.

In the general and more popular use of the term, rationalism is equivalent to a demand for a reasonable explanation in scientific terms. The rise of rationalism is thus in many respects identical with the development of the scientific spirit of inquiry. As such, it is opposed to mysticism and supernaturalism. Lecky, in his 'History of the Rise and Influence of Rationalism in Europe,' explains the word as follows: "By the spirit of rationalism, I understand not any class of definite doctrines or criticisms, but rather a certain cast of thought, or bias of reasoning, which has during the last three centuries gained a marked ascendancy in Europe. . . . At present, it will be sufficient to say, that it leads men on all occasions to subordinate dogmatic theology to the dictates of reason and of conscience, and, as a necessary consequence, greatly to restrict its influence upon life. It predisposes men, in history, to attribute all kinds of phenomena to natural rather than miraculous causes; in theology, to esteem succeeding systems the expressions of the wants and aspirations of that religious sentiment which is planted in all men; and, in ethics, to regard as duties only those which conscience reveals to be such." Between the claims of revealed religion and the spirit of rationalism the conflict has been especially sharp and long-continued. This opposition shows itself even before the birth of Christianity in almost all of the older religions. In Greece, for example, where religion was only to a very slight extent embodied in dogmas, the philosophers were nevertheless frequently charged with atheism, or with perverting and destroying the national religion through their rationalistic teachings. With the establishment of the Christian Church, the doctrines of religion were explicitly declared to be above reason and to rest upon a higher authority than human reason could afford. Nevertheless, from time to time there arose thinkers within the Church itself who strove to reduce the theological doctrines to a rationalistic

basis, interpreting them in such a way as to minimize or destroy the supernaturalistic elements which they contained. Of these mediæval rationalists Abelard (q.v.), 1079-1142, is perhaps the most famous. It was not until the 18th century, however, that rationalism became strong enough and bold enough to make open war upon the prevailing theological beliefs and doctrines. This century was called the age of enlightenment, and in it the demand arose on all sides that everything should be explained in terms of the clear and distinct ideas of reason, that mysteries and superstitions should be abolished, that the authority of Church and State should be limited and subordinated to the principles of reason and the interest of the individual members of society. The Deistic movement in England is especially noteworthy as maintaining the right of individual free thought in matters of religion, and as attacking the abuses and absurdities in the existing theological creeds. Lord Herbert of Cherbury and John Locke may be regarded as forerunners of English Deism (q.v.). The best-known representatives of the movement are John Toland (1670-1729), Anthony Collins (1676-1729), Matthew Tindal (1657-1733), Thomas Chubb (1679-1747) and Thomas Morgan. The influence of this movement was felt throughout Europe. In Voltaire it found a spokesman of extraordinary literary power who had also the courage to carry its principles to its logical conclusions.

The spirit of rationalism, in so far as it represents the claims of free scientific inquiry, may be said to have already won its triumph. This triumph too, it must be admitted, was largely the result of the enthusiastic zeal of the apostles of the enlightenment. Nevertheless, the spirit of modern inquiry has been profoundly modified in many respects during the 19th century. In the first place, it has lost the narrowness and hardness that it necessarily exhibited so long as a large share of its strength was expended in negative criticism and in making war upon prevailing creeds and institutions. In addition, it has been transformed by the historical and evolutionary conceptions that have become dominant in every field of inquiry, leading men's thoughts to problems of genesis and origin, and so to understand and sympathize with much that appeared absurd and unmeaning to the older rationalists. The 18th century rationalists regarded the world as static; they looked at each thing as it actually stood before them in their own day, and judged it by the unflinching standard that each individual was supposed to possess in the clear and distinct ideas of his own individual reason. The historical point of view has brought with it a broader conception of reason and what is rational; it has taught us that it is only in the light of its origin and function that a thing can properly be judged, and that, accordingly, there may be a truer rationality in historical creeds, beliefs and institutions than in the self-confidence of the individual of clear and distinct ideas who ventures to criticize what he does not understand.

The philosophical doctrine known as Rationalism owes its origin to Descartes (1596-1650), and has its home mainly in France and Germany, while empiricism (q.v.), the theory to which it was directly opposed, flourished mainly

in England. The rationalistic philosophers take mathematical demonstration as the perfect type of knowledge and seek to model their procedure in all fields of inquiry on what they assumed to be its method. From the chaotic and contradictory material supplied by sense-perception they believed that real knowledge, science, could not be attained. Mathematics, however, reaches its results in independence of such a source. It begins with fundamental principles and conceptions which are self-evident and proceeds by means of logical analysis and reasoning to show what further results are necessarily involved and implied in the starting-point. Now, the rationalistic thinkers maintain that what has been achieved in this particular science may be carried out universally by the application of the same method. That is, the true method of knowledge consists in first discovering by analysis the fundamental truths that lie at the basis of all thinking. These truths are not derived from experience, but, like the mathematical axioms and first principles, are native to the mind, innate ideas or *a priori* truths that are the starting-points for all demonstration and all science. When these are once discovered, it is the further task of philosophy to deduce by logical reasoning the further results that follow from them. In this way the rationalists supposed that it was possible to arrive at conclusions in philosophy that are as demonstrably certain as the propositions of geometry.

Besides Descartes, the chief representatives of rationalism are Spinoza (1632-77), who adopted the geometrical form of proof in his chief work, the 'Ethics'; Leibnitz (1646-1715), and Christian Wolff (1679-1754). The last-mentioned philosopher, though the least original, exercised a great influence over the thought of Germany by his terminology and by the systematic way in which he divided the field of philosophy into the so-called sciences of rational cosmology or physics, rational psychology, and rational theology. The first of these seeks to furnish demonstrative proof of the fundamental nature of the physical universe; for example, that it is limited in space, had a beginning in time, is made up of indivisible parts, etc. Rational psychology sets out from the conception of the soul as a spiritual substance and attempts to prove that it necessarily follows as a result of this initial conception, that the soul is simple, indivisible, indestructible and, therefore, immortal, and, moreover, that it possesses certain faculties, such as those of representation, desire, as essential to its true nature. In like manner, rational theology dealt in the same *a priori* and deductive way with the various proofs for the existence and attributes of God. This was the form of rationalism in which Kant was educated and it is against these so-called rationalistic sciences that he directs his attack in the dialectic of the 'Critique of Pure Reason.' The criticism of Kant was so penetrating and thoroughgoing that it annihilated at a blow the claims of rationalism. It did this by pointing out, in terms that could neither be mistaken nor denied, the falsity of the assumptions upon which this philosophical theory rests. Kant is thus the destroyer and finisher of rationalism.

Professor of Logic and Metaphysics, Cornell University.

RATIONALISTS. See RELIGIOUS SECTS.

RATISBON, rät's-bön (**REGENSBURG**, rä'gëns-boorg), Bavaria, Germany, 82 miles by rail northeast of Munich, partakes of the artistic tendencies of the latter. Chief among its public buildings and institutions are the Gothic cathedral, library, art-gallery, seminaries and glass-staining factory. Trade, facilitated by its favorable position on the Danube, is considerable. Ratisbon suffered much from bombardments at various periods of its history, especially in 1809, when it was stormed by the French. It became a free port in 1853. Pop. (1910) 52,624.

RATITÆ, rä-tītē, a group of birds broadly characterized as having a non-carinate sternum and little or no power of flight. The group originally was one of the two grand divisions of *Aves*, embracing all those whose sternum had no keel, as opposed to *Carinata*; but this character alone will not define the *Ratitæ* as at present constituted by the researches of Gadow and accepted by ornithologists generally. Its place is as a subdivision of the *Neornithes* (q.v.) co-ordinate with the *Odontolca* (*heperornis*, etc.) and the *Carinata*; and the sum of many anatomical peculiarities distinguishes the group, which consists of the ostriches, cassowaries, kiwis, moas, rocs (*Aepyornis*), and perhaps some of the fossil birds of Patagonia whose relationships are not yet perfectly clear. The conspicuous feature of all these is the rudimentary condition of the wings, so that the ratites are well-designated flightless birds, the disappearance of the tail and the great prominence of the functions and development of the legs and feet. These features are believed to be the result of changes, very long continued, from ancestors which possessed the power of flight and have lost it by disuse, and in adaptation to life upon plains and deserts. This group was introduced by Merrem in his 'Attempt at a Natural System of Birds,' and contains his genus 'Struthio,' since divided. Consult Evans, 'Birds' (1900); Newton, 'Dictionary of Birds' (1893-96); Stejneger, 'Standard Natural History' (Vol. IV, 1885).

RATKE, rät-kè, Wolfgang (better known by his Latinized name of RATICHUS), German educator: b. Wilster, Holstein, 18 Oct. 1571; d. Erfurt, 27 April 1635. He was trained in the Johanneum at Hamburg and the University of Rostock. Between 1603 and 1611 he lived in Holland and was the inaugurator of a new plan of school reform. The essence of his system was to discard the old memory and rote

method of teaching children; to interest them, by presenting things to their observation, and, afterward, names—a reversal of the method then in vogue; to teach them their mother tongue first and thence proceed to foreign languages. At first he met with little success in propagating his views. In 1618, however, he settled at Köthen, Anhalt, and Prince Ludwig von Anhalt furnished him with the means of opening a school to be conducted according to his own ideas. Owing to certain faults of his own, as well as to the unsettled religious condition of Germany at that time, he was obliged to leave Köthen and settled at Magdeburg in 1721. Here he made a second failure and afterward led a somewhat wandering life. But his influence upon his contemporaries and posterity was much greater than would be supposed from the failure of his own attempts to put his plan in practice. Consult Krause, 'Wolfgang Ratke, im Licht seiner und seiner Zeitgenossen Briefe' (1872); Schumann, 'Die echte Methode W. Ratkes' (1876).

RATON, rä-tôn', N. Mex., city, county-seat of Colfax County, on the Atchison, Topeka and Santa Fé Railroad, about 130 miles northeast of Santa Fé and eight miles south of the northern boundary of the State. In the vicinity are extensive coal fields. It is the commercial and industrial centre of a large region devoted chiefly to farming and stock raising. It has railroad shops, stock-yards, grain elevators, wholesale houses and brick and lumber yards. Pop. 4,539.

RATTAN, rät-tân, a product of *Calamus rotang*, a scandent palm of Ceylon, but also found in India and Burma. While this species furnishes the best commercial rattan, there are about 200 species in this genus, inhabiting tropical and subtropical Asia, Africa and Australia. The most important species other than the above are *C. rudentum*, *C. pachystemon* and *C. radiatus*, abounding throughout the damp forests of Ceylon up to 3,500 feet elevation. *C. rotang* and the first two species named above are manufactured into a great variety of useful articles such as baskets, chairs, the hoods of carts, and when split into strips can be twisted into cordage of great strength. *C. rotang* is often used in Eastern countries for rope bridges, or, used entire, is stretched across rivers as the supports of suspension bridges; and is also employed for the manufacture of Malacca canes. In China rattan is a favorite material for cordage, and the material also enters into the manufacture of umbrella handles and ribs, and as a substitute for whalebone. The cane is used for saddlery and harness and for wicker-work helmets, said to be sword-proof. The two smaller species (*C. pachystemon* and *C. radiatus*) are largely employed in the manufacture of baskets for the Ceylon tea gardens, used in picking the tea leaves. *C. radiatus* supplies the material for chair bottoms, being split into thin strips. In fact the many uses of rattan in Eastern countries are almost nameless. In the United States rattan is largely used for manufacturing chairs and other furniture, for chair-seating, baby-carriage bodies, baskets, floor mattings, brooms, corset-stays, whips and many other uses of minor importance. The "reed" used in raffia fancy-basket manufacture is the split inner portion of rattan dressed in

cylindrical form like the true reeds. See also **FIBRE**.

RATTANY, or **RHATANY**, a coarse plant of the genus *Krameria* and order *Polygalæ*, native to the Andean table-lands in Peru and Bolivia. The roots have medicinal value as an astringent, when finely powdered they furnish a frequent constituent of tooth-powders, and they also serve, especially in Portugal, to color wines ruby-red. This property is due to the presence of ratanhia tannic-acid. The root-bark also contains an almost insoluble free red substance called ratanhia-red.

RATTAZZI, rât-tât'sé, Marie Studolmine de Solms, French novelist: b. Waterford, Ireland, 1833; d. Paris, February 1902. She was the daughter of Sir Thomas Wyse, British Ambassador to Greece, and Letitia, eldest daughter of Lucien Bonaparte. She was married to Frederic de Solms, a rich native of Alsace in 1850, to Urbano Rattazzi (q.v.) in 1863 and to M. de Rute in 1877. Twice, in 1852 and 1864, she was exiled. She wrote much in prose and verse, and was a prominent figure in politics and society. She was one of the first woman journalists; for four years she wrote a feuilleton for the *Constitutionnel*, and also wrote for the *Pays* and the *Turf*. In the early days of the Second Empire she was a woman of great personal beauty and gathered around her in her salon men of all shades of opinion — Hugo, Rochefort, Semenuais, Sue, About, etc. In Italy she was called the 'Divina Fanciulla.' In 1881 she edited 'Rattazi et son Temps,' and in the last two or three years of her life she published two volumes of her own memoirs, and edited the *Nouvelle Revue Internationale*, to which she also contributed largely. Among her other works were 'Les Mariages d'une Creole' (1864); 'Si j'étais Reine' (1868); 'L'Aventurier des Colonies' (1885), a drama; and the volume of tales, 'Enigme sans Clef' (1894).

RATTAZZI, rât-tât'sé, Urbano, Italian statesman: b. Alessandria, 29 June 1808; d. Frosinone, 5 June 1873. He studied law at Turin and, after practising with marked success at the capital and at Casale, was elected a member of the Sardinian Parliament from his native town in 1848. He allied himself with the Liberal party and attained such speedy recognition that in August he was made Minister of Public Instruction. He left office after a few days, but in December of the same year assumed the portfolio of the Interior under Gioberti, exchanging it later for that of Justice. On the fall of the Gioberti ministry, Rattazzi was entrusted with the formation of a new cabinet (February 1849) but the disaster of Novara in the following month robbed him of power. From Democrat he now turned Moderate Liberal and formed the party of the left centre whose coalition with the right centre under Cavour (q.v.), the so-called "connubio," brought about the fall of the d'Azeglio Cabinet in November 1852 and the organization of a new ministry by Cavour. Rattazzi gave up the presidency of the Chamber to become in 1853 Minister of Justice, and later, of the Interior, and in the second capacity precipitated a bitter struggle with the Clerical party by the introduction of a law providing for the partial secularization of church property and restricting the

influence of the religious associations. He left the cabinet in 1858 but in July of the following year, after Villafranca, succeeded Cavour as head of the cabinet, only to give place to his predecessor within six months. His opposition to the cession of Savoy and Nice to France led to his retirement in 1860, but changing his views on this policy he became president of the lower chamber in the first Italian Parliament and in March 1862 succeeded Ricosoli in the government, retaining for himself the portfolios of Foreign Affairs and of the Interior. His course in checking the patriotic agitation against the Austrians in Lombardy and the papal rule in Rome brought him great unpopularity and in December 1862 he retired from office. Once more he succeeded Ricosoli, as Premier, in 1867, but again had to yield to the storm of popular anger aroused by his hostile attitude toward Garibaldi (q.v.) and he resigned in October of the same year.

RATTIGAN, Sir William Henry, English jurist: b. Delhi, British India, 4 Sept. 1842; d. London, 4 July 1905. He was educated at King's College, London; admitted to the bar in 1873; served four times as judge of the chief court of Punjab; was additional member of the supreme legislative council of India 1892-93, and member of the Punjab legislative council 1898-99. In 1895 he was knighted and in 1901 became member of Parliament for northeast Lanarks. He published 'De Jure Personarum' (1873); 'The Science of Jurisprudence' (3d ed., 1892); 'Private International Law' (1895), etc.

RATTLESNAKE, a distinctively American group of poisonous serpents characterized by a peculiar horny rattle appended to the tail. They belong to the suborder *Solenoglypha*, all the members of which are poisonous and have the fang-bearing maxillary bones erectile. To this suborder belong the Old World families of *Viperidæ* (vipers) and the *Crotalidæ*, or pit-vipers, which inhabit both hemispheres. The latter have the maxillary bone deeply excavated to lodge a sensory pit of unknown function opening on the face between the eye and nostril. There are two subfamilies, the *Lachninae*, which have no caudal rattle, and the *Crotalinae*, or rattlesnakes. The former includes the copper-head, water moccasin and fer-de-lance (qq.v.). the banana snake, whose presence in bunches of this fruit so often causes consternation on fruit ships and in storage houses, and numerous others of tropical America, India and the Malay Islands.

The *Crotalinae*, or rattlesnakes, represent the highest type of serpent development and specialization. The caudal rattle, from which they take their name, consists of a series of dry horny epidermal rings so loosely fitted that any movement causes them to knock together with a sharp rustling rattle. They are formed in the following manner: Several of the terminal vertebrae of the tail are coalesced to form a dilated vertically enlarged plate. This is covered with a thick vascular skin so cut by an annular constriction as to form a larger anterior, and a smaller posterior knob, which together may be considered to be a mold on which the joints of the rattle are formed. The epidermis covering this region is especially thick, and in the young snake forms a button

and ring, which are the only indications of the rattle. When the snake sloughs, the horny covering is loosened here as elsewhere and a new layer is formed beneath it; but instead of being cast off with the rest of the epidermis, the open end of the old horny ring fits over and by its elasticity clasps the new knob at the end of the tail, and by this means remains attached. With each subsequent molt a new ring and button are added, the latter serving to hold its predecessor in the series, and which continues to increase in size with the growth of the snake and its caudal knob. As well-fed snakes may slough three or four times a year, and as the rings sooner or later become worn out and detached, it is evident that the popular belief that the number of joints in the rattle indicate the years of the snake's age is unfounded. Rattles of more than 12 joints are rare, but one having 21 is known. When the snakes are irritated or angry, the end of the tail is more or less elevated and vibrated rapidly, producing a sound audible at a distance of 30 or 40 paces. Many snakes, both venomous and innocuous, have this habit of vibrating the tip of the tail when angry and many have a hard horny spur or cap at its end, but no others retain this through a succession of molts. Many fantastic theories have been proposed in explanation of the utility of the rattle, but it is probably little more than a recognition character, which helps to bring the sexes together and to segregate the species. However, it is probable that its sounding formerly saved the lives of many rattlesnakes by warning large animals acquainted with their deadly powers from the vicinity, but since the advent of the white man it has had a precisely opposite result.

Poison.—The venom apparatus of the rattlesnakes is the most complete and effective contrivance imaginable for injecting the poisonous fluid into the circulation of a victim. The maxillary bones are very short and are freely movable on an articulation with the prefrontals. Upon them are attached the venom fangs at such an angle that with the movements of the maxillary they may be depressed in a fold of mucous membrane or erected vertically in the very front of the mouth in a most effective position for striking. The tooth substance of the fang is folded into a tubular form, with an opening at the base to receive the end of the venom duct and another near the front face of the needle-pointed tip. Behind the functional fang, which may be nearly an inch long in large snakes, is a succession of smaller reserve fangs, which become functional in order as their predecessors are lost. The venom gland, which corresponds to the parotid salivary gland of other animals, is situated on the cheek and has a duct running to a sinus at the base of the fang. All of the muscles and other parts are so arranged that the same movements that open the mouth and press the horizontal pterygoid bones forward to erect the maxillaries with their fangs also compress the poison gland and squeeze out its secretion. Cope describes the biting movement as three-fold: "First, there is the spring of the body, which never exceeds two-thirds of its length; second, the bite proper, caused by the seizing of the jaws; and, third, the clutch with the fangs themselves, which are moved freely backward and forward." This movement

of the fangs may be easily seen by holding a rattlesnake so that it cannot strike, when drops of the pale yellow venom may be seen to fall from their tips and are sometimes blown from the mouth by forcible expirations. The active principles of the venom are several soluble proteids, one of which has a disorganizing effect on tissues with which it comes in contact and another is a powerful heart and respiratory depressor. The immediate effect of a bite is severe burning pain followed in 10 or 15 minutes by prostration, with dizziness, vomiting and cold sweats; the heart action is very feeble and the pupil dilated. This condition gives way in from 12 to 15 hours to one of fever and difficult respiration, while the part affected becomes greatly swollen and the neighborhood of the wound suppurates. Death may occur in either of these stages or as a result of secondary gangrene. Treatment to be effective must be prompt and thorough. A ligature should be applied above the wound and the latter enlarged with a clean knife until the blood flows freely. Permanganate of potash, bleaching powder, chromic acid, silver nitrate or other substances which render the active albumens insoluble should be applied to the wound. Small and frequent doses of whisky, strychnine or ammonia should be administered as a stimulant, but an excess of alcohol may increase the depression. Every effort should be made to press or draw the poison from the wound before the ligature is removed, but sucking with the mouth is always dangerous.

Species of Rattlesnake.—Of rattlesnakes three species of *Sistrurus* and 16 of *Crotalus* have been described, three of which are South and Central and the rest North American. None occurs in the West Indies. The species of *Sistrurus* are small snakes with the snout and frontal region of the head covered with large plates. The ground rattlesnake or massasauga (*S. catenatus*) is found on low prairie lands from Ohio and Minnesota southward, but is now rare or exterminated in all settled parts. It reaches a length of three feet and is not considered especially dangerous. About six young are born alive in September; and this is one of the snakes for which it is pretty clearly established that the newly-hatched young seek refuge from danger in the mouth and gullet of the mother. A related species (*S. miliarius*) is found in the Southern States.

In the genus *Crotalus* the entire top of the head is covered with small scales. The common or banded rattlesnake (*C. horridus*) was formerly abundant throughout the entire eastern United States and it is the only species found in southern New England and the Middle States, but has been largely exterminated by the white man and his companion, the hog. The latter in roaming the woods in search of mast, etc., never fails to kill and devour the rattlesnake whenever possible. It is commonly believed that the hog is immune to snake-bites, but the truth is that the poison is dissipated in the thick skin and layer of subcutaneous fat and never reaches the vascular tissues beneath. This rattlesnake prefers sparsely wooded rocky ridges with sunny exposures and in such localities is still common in the mountains from Pennsylvania to Tennessee. It is a sluggish and generally peaceful creature, and seldom bites

except to secure food, unless it be trod upon or startled. When about to strike it coils with the head in the middle and elevated and the rattle sounding, delivers a lightning-like blow and immediately recoils or slowly retreats. It seldom attacks without provocation or follows a foe. All kinds of small mammals, especially mice, and occasionally birds, are its food, and it drinks water freely. The cold months of the year are passed in hibernation and frequently large numbers of these snakes congregate in caves or beneath rocks for this purpose. Mating takes place in the early summer and about September from six to nine young about nine inches long are born alive. A length of five feet is sometimes attained, but ordinary examples seldom exceed four. Among the natural enemies of the rattlesnake are the kingsnake and blacksnake, birds of prey and herons. The diamond or water rattlesnake (*C. adamanteus*) reaches a length of more than eight feet and a circumference of 15 inches and is not only the largest of the rattlesnakes, but the bulkiest of all poisonous snakes, being exceeded in length only by the slender snake-eating cobra. It inhabits the Southern States and is particularly abundant on the Florida Keys. Except that it prefers the vicinity of water, in which it swims freely, its habits are much like those of the common species. Because of its great size, and the large amount of venom that it secretes, this is an extremely dangerous reptile; it is also sometimes inclined to be aggressive. The prairie rattlesnake (*C. confluentus*) inhabits most parts of the Western plains and deserts and is exceedingly abundant in unsettled regions. This is the species which plays a part in the famous triple alliance of prairie-dog, owl and rattlesnake, which, although popularly supposed to be a most amicable arrangement, is at best a state of armed neutrality and frequently of open warfare. The owls and snakes seek the burrows of the marmot as safe retreats and nesting sites, as well as for the purpose of feeding on the young marmots, while the latter frequently show their resentment of the intrusion in a variety of ways. A very distinct species is the horned rattlesnake (*C. cerastes*), in which the superciliary scales are produced into a pair of prominent horns surmounting the eyes. It is abundant in the desert region of the Southwest, especially about Death Valley, and is known in Arizona as "sidewinder" from its peculiar habit of retreating sidewise from an intruder. Several other species inhabit these hot dry regions.

Service to Man.—Rattlesnakes possess a certain economic importance. As checks on the increase of the native mice and rats, they, in common with many other snakes, perform an important service. Their venomous qualities are such a menace to man and beast as to render their destruction both expedient and certain in all thickly settled districts. By the Indians and by the whites in certain parts of the South their flesh is relished; an oil or salve, supposed by the credulous to possess peculiar medicinal virtues, is claimed to be manufactured from their livers and other fatty parts; and the use of the skin for making purses, belts and other small articles is well known. Certain tribes of Indians employ these snakes in their ceremonials and others formerly poisoned the tips of their war-arrows with rattlesnake venom, while the rat-

tles always figured among the charms of the medicine-man.

RATTRAY, rā'trā, William Jordan, Canadian journalist: b. London, England, 1835; d. Toronto, Canada, 26 Sept. 1883. He went to Canada with his parents in 1848, was graduated from the University of Toronto in 1858 and engaged in journalism as an editorial writer on the *Toronto Mail*. He also contributed to the *Canadian Monthly* and other periodicals and established a reputation as an able defender of Christianity against agnosticism. Author of 'The Scot in British North America' (4 vols., 1883).

RAU, row, Charles, American archaeologist: b. Verviers, Belgium, 1826; d. Philadelphia, Pa., 25 July 1887. He was educated at the University of Heidelberg and came to this country in 1848, where he engaged in teaching. From 1875 until his death he was curator in the National Museum at Washington, D. C., and devoted himself to the study of American archaeology, on which he became a recognized authority. He wrote 'Early Man in Europe' (1876); 'The Palenque Tablet in the United States National Museum' (1879); 'Articles on Anthropological Subjects, 1853-1877' (1882). He left unfinished a work on the types of early American implements, and what was projected to be an exhaustive record of American archaeology. His great library and collections were bequeathed to the National Museum.

RAU, Karl Heinrich, German political economist: b. Erlangen, 1792; d. 1870. He received his education at the University of Erlangen, was privat docent there in 1812, becoming professor of political economy there in 1818. Four years later he removed to Heidelberg in a similar capacity. In 1835 he founded the *Archiv der politischen Oekonomie und Polizeiwissenschaft*. He is the author of 'Ueber das Zunftwesen und die Folgen seiner Aufhebung' (1816); 'Grundriss der Kameralwissenschaft und Wirtschaftslehre' (1823); 'Lehrbuch der politischen Oekonomie' (1826-37).

RAUCH, rowch, Christian Daniel, German sculptor: b. Arolsen, western Germany, 2 Jan. 1777; d. Dresden, 3 Dec. 1857. In Arolsen he received his first instruction in art from the sculptor Valentin, under whom he executed ornamental work chiefly. Going to Cassel he became a pupil of Kuhl, the sculptor, and was appointed groom of the chamber in the king's household at Berlin. This gave him an opportunity of advancing in his art, and in 1802 he exhibited his 'Sleeping Endymion' and modeled a bust of Queen Louise (1804), which he subsequently executed in marble at Rome. In this city he found a patron in Humboldt, as well as in the first sculptors of the time, Canova and Thorwaldsen. Among his Roman work

of early days must be mentioned the busts of the poet Werner, the life-sized busts of Queen Louise, Count Weyerski, the painter Raphael Mengs, executed under the commission of Ludwig of Bavaria, and the bassi-relievi of 'Hippolytus and Phædra' and 'Mars and Venus Wounded by Diomedes.' By 1824 he had executed 70 busts in marble of which 20 were of colossal size. His colossal bronze statues of Blücher are 13 feet in height, and he also executed the greater part of the 12 statues in iron which compose the national monument at Kreuzberg, near Berlin. One of his finest works is the group 'Faith, Hope and Charity,' which he presented to his native town, Arolsen, while his crowning work as a portrait and historic sculptor is his statue of Frederick the Great at Berlin (1851), the result of 20 years' labor. He was one of the first, if not the very first, among German sculptors of his time, combining in his work the pure lines of transcendent dignity and grace with genuine portraiture of the individual. There is a poetic freedom in his conception of ideal subjects which does not yet overstep the limits of truth and fidelity to nature, and he may be safely styled the founder of the great Berlin school of sculpture. Consult Eggers, 'Chr. n. Rauch' (1873); 'Rauch und Goethe, urkundliche Mitteilungen' (1880).

RAUHES HAUS, row'ēs hows (corrupted from 'Ruges Haus'), an educational and benevolent institution at Horn, near Hamburg, founded in 1833 by Johanne Heinrich Wichern (1808-81), who long remained at its head. It is connected with the German Home Mission, and besides forming a refuge for neglected children receives boarding pupils from the higher classes, and serves as a training school for those wishing to become teachers, superintendents or assistants in hospitals, reformatories, houses of correction and the like. It is supported by voluntary contributions, the profits arising from the productive enterprises carried on in connection with it and the fees of the richer pupils. In recent years there has been an average of 100 poor and neglected children, about one-third girls, receiving instruction within its walls. They live in 'families' of from 12 to 15, each 'family' being under the care of one of the adult members of the mission training school. The educational department is in the hands of assistants, who also take part in the instruction of the institution, in order to prepare themselves for the work of the Home Mission in other localities. This indeed has become one of the most important features of the work carried on by the Rauhes Haus, and its graduates are found in every field of charitable work in Germany. The whole staff of assistants, consisting of young men of 20 to 29 years of age, are formed into a kind of society (*Brüderschaft*). Since 1844 the institution has carried on a printing and book-binding business. Its organ is the *Fliegende Blätter*.

RAUM, rowm, Green Berry, American lawyer: b. Gokonda, Ill., 3 Dec. 1829; d. Chicago, Ill., 18 Dec. 1909. He was admitted to the bar in 1853; removed to Kansas and served in the Union army in the Civil War, rising to the rank of brigadier-general of volunteers. He sat in Congress 1866-69; was commissioner of internal revenue 1876-83, and United States commissioner of pensions 1889-93. He pub-

lished 'The Existing Conflict between Republican Government and Southern Oligarchy' (1884); 'History of Illinois Republicanism' (1900).

RAUMER, row'mër, Friedrich Ludwig Georg von, German historian: b. Wörlitz, near Dessau, Anhalt, 14 May 1781; d. Berlin, Germany, 14 June 1873. He studied law at Halle and Göttingen, and entered the Prussian state service in 1801. In 1811 he accepted the chair of political economy at Breslau, and in 1819 was called to Berlin. He was for some time secretary of the Berlin Academy, and at different times between 1816-55 traveled extensively through Europe and the United States. In 1848 he was elected to the Parliament of Frankfurt, and was sent to Paris as Ambassador. He was a member of the House of Lords of Prussia from 1851 until his death. He founded and edited in 1830-67 'Historisches Taschenbuch.' The first scientific historian to popularize history in German, Von Raumer wrote 'Geschichte der Hohenstaufen und ihrer Zeit' (1823-25); 'Briefe aus Paris zur Erläuterung der Geschichte des 16 und 17 Jahrh' (1831); 'Ueber die geschichtliche Entwicklung der Begriffe von Recht, Staat und Politik' (1832); 'Geschichte Europas seit dem Ende des 15. Jahrhunderts' (1832-50); 'Beiträge zur Neuern Geschichte aus dem Brit. Museum, etc.' (1836-39); 'Die Vereinigten Staaten von Nordamerika' (1845); 'Handbuch zur Geschichte der Litteratur' (1864-66), besides special works on 'Prussian Municipal Law' (1828); 'England, 1835' (1836); 'England, 1841' (1842), and 'Italy' (1840).

RAUMER, Karl Georg von, German geologist and educator, brother of the preceding: b. Wörlitz, Germany, 9 April 1783; d. Erlangen, Germany, 2 June 1865. He was educated in Göttingen, Halle and Freiberg, and in 1811 became professor of mineralogy at Breslau, was called to Halle in 1819 and in 1827 settled permanently as professor of natural history at Erlangen. He published 'Geognostische Fragmente' (1811); 'A B C Buch der Krystallkunde' (1817, 1821); 'Lehrbuch der allgemeinen Geographie' (1832); 'Geschichte der Pädagogik' (1843-51); 'Beschreibung der Erdoberfläche' (6th ed., 1866), etc. Consult his autobiography (1866).

RAUMER, Rudolph von, German philologist, son of Karl Georg von Raumer: b. Breslau, Germany, 14 April 1815; d. Erlangen, Germany, August 1876. He was privat docent at Erlangen in 1840-46; professor there in 1846-76, and published 'Untersuchungen über die Urverwandtschaft der semitischen und indo-europäischen Sprachen' (1868 et seq.).

RAUPACH, row'pāh, Ernst Benjamin Salomo, German dramatic poet: b. Straupitz, near Liegnitz, 21 May 1784; d. Berlin, 18 March 1852. He studied theology at Halle, afterward went as a tutor to Russia, and in 1816 obtained a chair in the philosophical faculty of the University of Saint Petersburg; but quitted the country in 1822, and after various changes finally settled, in 1824, in Berlin, where he employed himself chiefly in writing for the stage. His dramatic works have been collected and published in two divisions, the one containing his comic pieces, under the name of 'Drama-

tische Werke komischer Gattung' (1828-35); and the other, 'Dramatische Werke ernster Gattung' (1830-43). In his earlier works he was an imitator of Schiller, and some of the tragedies belonging to this period, such as 'Die Erdennacht,' show much real power. His popular success was considerable; but his dramas became more and more trivial in content. They display, however, considerable knowledge of stage effect, great creative power and a wealth of verbal wit. His early plays include 'The Princess Chawansky' (1818); 'Die Gefesselten' (1821); 'Der Liebel Zauberkreis' (1824); 'Isidar und Olga' (1826); and 'Die Tocuter der Luft' (1829); his comedies 'Die Schleichhändler'; 'Der Zeitgeist,' and 'Das Sonnett'; his farces 'Deuken Cäsar,' and 'Schelle im Monde'; his posthumous works 'Jacobine von Holland,' 'Der Kegelspider,' 'Mulier tacat in Ecclesia' (1853), and 'Seed and Fruit' (1854). A life of the dramatist was published by Pauline Raupach (1853).

RAUPP, rowp, Karl, German painter: b. Darmstadt, 1837. He began as a landscape painter, and between 1856 and 1858 studied genre under J. Becker at Frankfurt, and under Karl Piloty at Munich Academy from 1860 to 1865. Subsequently he opened a studio, taking private pupils in painting, and in 1868 his reputation as a teacher gained for him the position of professor in the art school at Nuremberg, which he held up to 1879, when he was appointed professor in the academy at Munich. Among his works may be mentioned 'A Boating Party on the Chiem See'; 'Home Before a Storm'; 'A Calm'; 'Ave Maria'; 'Sport and Work'; 'Starting Home from the Monastery School.'

RAUSCHENBUSCH, rou'shën-bûsh, Walter, American Baptist clergyman and author: b. Rochester, N. Y., 4 Oct. 1861. He was educated at the classical gymnasium, Gutersloh, Germany, the University of Rochester and the Rochester Theological Seminary, and was ordained in the Baptist ministry in 1886. He was engaged in religious work among German immigrants in 1886-97, and in educating German pastors in 1897-1902. Since 1902 he has been professor of church history at the Rochester Theological Seminary. He lectured at Berkeley College, Cal., in 1910; at the Ohio Wesleyan University in 1911 and at Grinnell College in 1914. Author of 'Christianity and the Social Crisis' (1907); 'Prayers of the Social Awakening' (1910); 'Unto Me' (1912); 'Dare We Be Christians?' (1914); 'Theology for the Social Gospel' (1917), etc.

RAVAILLAC, François, frân-swā rā-vā-yāk, French assassin: b. Tournes, near Angoulême, 1578; d. Paris, 27 May 1610. He was successively valet to an attorney, in which situation he learned to read and write, attorney's clerk and schoolmaster. He could never succeed in any undertaking, however, and was thrown into Angoulême prison for debt, where he remained for a considerable time. At last he was released, and turned out into the world a beggar. He entered the order of the Feuillants, but was expelled shortly afterward as a visionary. His naturally gloomy disposition degenerated into fanaticism when he began to meddle in the religious controversies that distracted France. He came to consider King Henry IV as the arch enemy of the Church,

to destroy whom would be a meritorious work. On 14 May 1610, while the king's carriage was standing in the street, Ravallac approached and stabbed him. He was condemned to be torn to pieces by four horses, and this he underwent, previously declaring that he had no accomplices to his crime. Henri Martin in his 'Histoire de France' and M. Poirson in his 'Histoire de Henri IV' concluded, after an examination of all available evidence, that the crime was wholly due to monomania, resulting from fanaticism.

RAVANA, rā-vā-nā, in Hindu mythology, one of the Rakshasa, a class of evil spirits or demons, who, as attendants on Kuvera, the god of riches, were guardians of his treasures, and had the power of assuming any shape at will. They were cruel, hideous monsters, ever ready to oppose the gods. At the time of Rama, Ravana ruled over Lanka, or Ceylon, and having carried off Sita, the wife of Rama, to his palace, was ultimately conquered and slain by the latter. He is described as a giant with 10 faces, who in consequence of austerities and devotion had obtained from Siva a promise which bestowed on him immunity from the power of demons and gods. Vishnu became incarnate as Rama, and hence killed the demon giant, whose kingdom had been invaded by men with the assistance of monkeys, against whom Ravana, in scorn, had omitted to make any stipulations in his compact with Siva.

RAVEN, a typical species (*Corvus corax*) of the crow family (*Corvidæ*), of which, as indeed of all passerine birds, it is the largest representative. The size is quite variable, but is generally about two feet in length and four feet in expanse. Plumage, bill and feet are all black, the former with rich purple and violet lustres, but duller in the young and females, which are likewise smaller. The raven inhabits Europe, a large part of Asia, and North America from the Arctic Ocean to Guatemala. In North America two sub-specific forms are found, *C. corax sinuatus* being the western, and *C. corax principalis* the larger northern and eastern race. The former is generally abundant in the Rocky Mountain region; the latter has been largely exterminated in the eastern United States, but is still found in many inaccessible waste and mountain districts and reaches a very large size in Labrador and northward. Northwardly the raven is migratory, but may withstand the cold of the severest winters, as it often does in Canada and about the Great Lakes.

It is most abundant in rocky districts, near the banks of lakes and rivers, and is generally seen alone or in pairs, but sometimes in small flocks after the breeding season; the flight is rapid, elevated and protracted, often sailing for hours at a time at a great height; on the ground the gait is grave and dignified, with frequent opening of the wings. It is truly omnivorous, but by preference carnivorous, eating small animals of all kinds, eggs and young birds, carrion, dead fish, mollusks, crustaceans, insects, nuts and berries. The European raven is reputed to destroy young rabbits and even lambs. It disgorges indigestible substances, as bones, hair and feathers, like birds of prey. It is very wary and cunning and is rarely caught in traps or shot by the hunter, but it often falls a victim

to the poisoned baits set by the trappers for the fur-bearing animals. It breeds according to latitude, between January and June, making a rude nest on inaccessible cliffs or tall trees, repairing the same for years in succession: the eggs are four to eight, two inches long, light greenish blue with numerous light purple and yellowish brown blotches, especially at the larger end; incubation lasts about three weeks, and the young remain in the nest several weeks before they are able to fly, fed at first on the half digested food disgorged by the parents; only one brood is raised in a year, and this is bravely and successfully defended against the largest birds of prey. The raven is easily domesticated by kindness, and becomes much attached to its master, following him like a dog. Like others of the family it can be taught to imitate the human voice and to pronounce a few words with great distinctness; but the natural note is a deep, hoarse croak. The white-necked raven (*C. cryptoleucus*) of Mexico and the southwestern United States has the concealed bases of the neck feathers pure white. Several other raven-like species inhabit Africa. The large size, black color, mournful croak, charnel-house habits, together with the boldness, sagacity and wariness of the raven, have combined to make it an object of superstitious fear and hate. As a bird of ill-omen it was watched by the ancient augurs with close attention; it holds a prominent place in mythology and folklore, and receives frequent notice in literature.

RAVEN, The. 'The Raven' by Edgar Allan Poe is the one of his poems which is most inseparably connected with his name in common recollection. It is entirely expressive of the dominant sentiment of his life, the longing and regret for beauty which he had once known; it is an excellent example of his most popular qualities as a versifier; and he himself has selected it as a means of explaining how a poet might develop his ideas into poetic form. Like 'Annabel Lee,' 'Ulalume' and others of Poe's best-known verse, 'The Raven' is a recurrence of the thought of a beautiful love early known and early lost. In its form it has all the quality of softness and sonorosity, of repetition and refrain which will be found elsewhere in Poe. In 'The Philosophy of Composition' Poe explains the steps by which these elements were built up and combined into the present poem. It is possible that he tells exactly what took place in his own mind. He was, however, rather fond of boasting people; he was also fond of exact intellectual manipulation; and it is very possible that his account is really an after-statement of what might have been. However that may be, the poem is a wonderful example of the emotional, even sentimental, lyric of the middle of the 19th century. It is a mistake to think of Poe's poetry as being more music than meaning. 'The Raven' has a very distinct meaning although not such as could easily be reduced to a systematic statement. In our own day such reveries and meditations seem sentimental and old-fashioned; a century ago they were the natural moods of hundreds of young men. And no poem in our literature better expresses just the mood that in that post-Byronic day was so common, not even anything by Byron himself.

As an expression of its author and its own time 'The Raven' is perfect. It realises an ideal of beauty which is rare to-day and which many to-day find it impossible to appreciate, but it is an ideal of beauty and it is realised.

EDWARD EVERETT HALE.

RAVENEL, Henry William, American botanist: b. Berkeley, S. C., 19 May 1814; d. Aiken, S. C., 17 July 1887. He was graduated from South Carolina College in 1832, made a life study of the fungi and cryptogams and became one of the best botanical authorities in the United States. He made a critical study of the phanogams of South Carolina, was botanist of the government commission to Texas in 1869 and was agricultural editor of the *Weekly News and Courier*. The genus *Ravenelia* of the *Uredineæ* is named in his honor. He was credited with being the only American after the Rev. Moses A. Curtis, who knew specifically the fungi of the United States. The University of North Carolina gave him the degree of LL.D. in 1886. He wrote 'Fungi Caroliniani Exsiccati' (1853-60); and with M. C. Cooke 'Fungi Americani Exsiccati' (1878-82).

RAVENNA, rà-vèn'a, capital of the Italian province of the same name, in the compartimento of Emilia, about 45 miles east of Bologna. It is situated on marshy ground which was, within historic times, a lagoon and the scenes of extensive maritime movement. The Corsini Canal and the two non-navigable streams, Montone and Ronco, connect Ravenna with the Adriatic, where there is a harbor at the mouth of the canal. The city has also railway connection with Bologna, on the west, Terrara, on the north, Rimini, on the south coast by the Adriatic Railways, which skirting the west shore of the Adriatic joins Ravenna with Brindisi in the far south. The connection with other places along the shore of the "Boot" is made by the Mediterranean Railways. Ravenna is joined to all the great western centres of commercial activity by lines of railway connecting with the Adriatic Railways. It has extensive parks and gardens, most of which lie outside the compact centre of the city, which is occupied by the Piazza Vittorio Emanuele. This Piazza, and other public squares and parks, possess many interesting statues and other sculptured work. Owing to the fact that it was an imperial, political and ecclesiastical centre for many years, Ravenna is now one of the greatest depositories of ecclesiastical architectural art in Italy, more especially of the art of the 5th, 6th, 7th and 8th centuries, which is a curious mingling of Roman, early Christian and Byzantine construction. Among the notable ecclesiastical edifices of the city, with the date of completion in each case, are Ecclesia Ursiana, known as the Metropolitan Church (390), San Giovanni Evangelista (425), Santa Agata (435), San Pier Crisologo (450), San Giovanni Battista (450), Nazario Celso (450), San Pier Maggiore (458), also called San Francesco, San Teodoro (526), also known as Santo Spirito, Santa Maria in Cosmodin (526), San Martino (526), now called Apollinare Nuovo, San Vitale (530), Santa Maria Maggiore (530), San Apollinare in Classe (535). The early cathedral, completed in 390, was destroyed toward the middle of the 18th century, and only some small parts of it and some decorations remain incor-

porated in the modern edifice. From 404 to 455, when Vienna was the official imperial residence, was a period of great architectural activity in the city. This includes six great churches and the Basilica Petriana, which has been demolished. Most of the other churches have been remodeled, added to or almost altogether rebuilt, but they all have incorporated in them interesting reminders of the original structures which preceded them. The modern churches are rich in mosaics, capitals, columns, crypts, frescoes, statuary, wall decorations and other paintings. The close of the period above indicated showed a very decided decrease in the building activity and art creation of Ravenna. But the reign of Theodoric (493-526) again awakened the latent artistic life of the city. Theodoric himself built a huge palace in the eastern quarter of the capital; but this has long since disappeared; and he also erected for himself a massive marble mausoleum at the northeast of the city. This building, which is still standing, is circular, two stories in height and crowned by a monster monolith of more than 300 tons weight. It is now a church dedicated to the Virgin. San Apollinare Nuovo was built by Theodoric himself. In his day it was the largest and one of the handsomest of the Arian churches. The impetus given to building and art by Theodoric was communicated to the reigns of several of his successors. A part of the activity of this period is indicated by the list of prominent churches already cited. The city is rich in remains of the past and of the imperial and ecclesiastical occupations, in museums, tombs and other historical landmarks, among these being the palace and tomb of Theodoric already mentioned, the tomb of Dante and the temple containing it, Lord Byron's house, old Roman and other roads in the neighborhood and buried and partially excavated ruins of the ancient city. Near to the modern city are also remains of the ancient harbor; in the near-by marshes stands the vast ecclesiastical edifice of San Apollinare in Classe, with its fine mosaics of the 6th and 7th centuries. Among the other notable monuments of the city are the granite columns of the Piazza Vittorio Emanuele set up there by the Venetians (1483) and the statues of San Apollinaris and San Vitalis.

Industries.—Among the industries of Ravenna are lace manufacture, silk raising, wine manufacture, grape growing, spinning, weaving. The raising of grain, fruit, fishing and the making of glass, leather, bricks, musical and agricultural implements have tended lately to increase the commercial activity of the city.

History.—Ravenna is one of the most ancient cities of Italy. Pliny says it was founded by the Sabines. In 191 a.c. it became part of the Roman dominions in Gallia Cisalpina. Augustus made Ravenna one of the important stations for his fleet, and by turning a branch of the Po through the city on its way to the Adriatic, increased the port facilities so as to accommodate a very considerable portion of the "upper sea" fleet, which was apparently composed of vessels of lighter draught, for we are assured that its situation "in the sea," the devious nature of the water-ways leading to it and their shallowness made it almost impregnable. For this reason and its apparent healthfulness it was the residence of numerous

emperors, among them Odoacer, who made his final stand against Theodoric, the leader of the Ostrogoths, sustaining a siege of three years conducted from land and sea. A few days after his surrender he was murdered by Theodoric, who made Ravenna his official residence in 493. During the following 33 years of his reign Theodoric lavished all his care on Ravenna, making it one of the most noted cities in his domains, and the pride of the Goths, who retained their power there for many years after they had lost Rome. In 539 Belisarius conquered Ravenna and added it to the Roman Empire of Justinian, which formed a part of his Byzantine dominions, and to which it was destined to remain joined for over 200 years, as the centre of Byzantine power in Italy. Aistulf the Lombard captured Ravenna in 752 but soon lost it to the Frankish king Pepin. In the 13th century it and the surrounding country became an independent republic; but was afterward subjected successively to the Polentani, the Venetian and the papal authorities, remaining finally part of the papal see from 1509 to 1859, since which time it has formed a part of the Italian union.

Bibliography.—Agnellus, 'Liber Pontificalis Ecclesie Ravennatis' (written about 840); Allen and Williamson, 'Cities of Northern Italy' (Boston 1906); Blashfield, 'Italian Cities' (New York 1912); Bormann, 'Corpus Inscript' (Berlin 1888); Diehl, 'Ravennae, études d'archéologie byzantine' (Paris 1855); Goetz, 'Ravenna' (Leipzig 1901); Gregorovius, 'Wanderjahre in Italien' (Vol. IV, Leipzig 1892); Gsell-Fels, 'Oberitalien und Mittelitalien' (Leipzig 1912); Pasolini dall' Onda, 'Ravenna e le sue grandi memorie' (Rome 1912); Ricci, 'Ravenna' (Bergamo 1902); Rivoira, 'Origini dell' Architettura Lombarda' (Rome 1901); Quast, 'Die altchristlichen Bauwerke Von Ravenna' (Berlin 1842).

RAVENNA, Ohio, township, city and county-seat of Portage County, on the Baltimore and Ohio, the Erie and the Pennsylvania railroads, about 28 miles southeast of Cleveland. It is in an agricultural region, and has extensive industrial interests. The chief manufacturing establishments are foundries, machine shops, furniture factories, brick and tile works, electrical supply works, flour and lumber mills, iron and boiler works and cigar factories. It has a large trade in farm, clay and iron products and in livestock. In the vicinity are a number of small and beautiful lakes, which have been made popular outing places. Pop. township, 6,451; city, 5,310.

RAVENNA GRASS. See GRASSES IN THE UNITED STATES.

RAVENSCROFT, rä'venz-kroft, Edward, English dramatist, who flourished between 1671 and 1700. He was exceedingly popular in his day, though his work was never original, consisting of translations from older plays, and at times he even borrowed from his own previous works. His first play was 'Mamamouchi' (1671), taken from Molière's 'The Gentleman Citizen.' His plays include 'The Wrangling Lovers' (1676), after Corneille; 'Scaramouch, a Philosopher' (1677); 'King Edward and Alfrede' (1677); 'Ignoramus' (1678); 'Dame Dobson' (1683); 'The Canterbury Guests'

(1695); 'The Italian Husband' (1698); 'The London Cuckolds' (published 1783), etc.

RAVENS-CROFT, Thomas, English composer: b. near London, 1592; d. London, 1635. He was educated for his profession in Saint Paul's choir, and at 15 received the degree of bachelor of music from Cambridge. In 1611 he published a collection of 23 part-songs, under the title 'Melismata,' which are of remarkable beauty. Musical tradition has ascribed to him the compilation of two earlier works, similar in character to his 'Melismata,' the 'Pammelia,' comprising 100 pieces, and the 'Deuteromelia,' containing 32, both dated 1609. In 1614 appeared his 'Brief Discourses,' another collection of 20 part-songs to which he has prefixed an essay on the ancient musical modes. In 1621 he published his 'Whole Book of Psalms,' containing a chant for each psalm, many new, and all harmonized in four parts by Tallis, John Milton (the poet's father), Ravenscroft himself and other musicians. The Roxburghe Club published selections from the 'Melismata,' 'Brief Discourses,' 'Pammelia' and 'Deuteromelia' in 1823.

RAVENSHOE, rá'vénz-hô, a novel by Henry Kingsley, published in 1862. The House of Ravenshoe, in Stonington, Ireland, is the scene of this novel; and the principal actors are the members of the noble family of Ravenshoe. The plot is remarkable for its complexity, and the book contains many bits of piquant humor.

RAVENSTEIN, rá'vén-stín, Ernst George, Anglo-German geographer and statistician: b. Frankfurt-on-the-Main, 30 Dec. 1834; d. 13 March 1913. He was educated privately and in 1852 removed to London. In 1855-75 he was engaged in the topographical (now intelligence) department of the War Office, was a member of the council of the Royal Statistical Society in 1877-92 and of the Royal Geographical Society in 1894-96. He founded the German Gymnastic Society in 1861 and served as its president for 10 years and in 1882-83 he was professor of geography at Bedford College. He published 'The Russians on the Amur' (1861); 'Geographie und Statistik des Britischen Reiches' (1863); 'Systematic Atlas' (1864); 'Map, Equatorial Africa' (1884); 'Handy Volume Atlas' (1895, 1907); 'The Strange Adventures of Andrew Battell' (1901); 'A Life's Work' (1908); 'The New Census Physical, Pictorial and Descriptive Atlas of the World' (1911).

RAVESTEIJN, rá'vè-stín, Jan van, Dutch painter: b. The Hague, about 1572; d. there, 21 June 1657. He was elected into the old Painters' Guild of Saint Luke at The Hague in 1598; the new guild was organized in 1655, and a Jan van Ravesteijn is enrolled among its members, but this may have been his son who bore the same name. He probably began his artistic studies under Frans Hals. His special department was portrait, in which he took rank among the first painters of Holland. Two large pictures of his with grouped portraits are to be seen in the Hall of the Company of Archers at The Hague; and in that city and at Antwerp are several portraits of individuals. His portrait picture of his own family is at Brunswick. His faces are life-like, his handling vigorous

and his coloring transparent, although somewhat too red to be quite natural.

RAVIGNAN, rà-vén-yân, Gustave Xavier Delacroix de, French Jesuit pulpit orator: b. Bayonne, 1 Dec. 1795; d. Paris, 26 Feb. 1858. He had already enlisted in the Bourbon cause in 1815, and, after juristic studies, been made auditor of the Paris Supreme Court (1817) and substitute Attorney-General (1821), when in 1822 he entered the Jesuit novitiate at Montrouge. In July 1828 he was ordained priest, and subsequently was professor of theology at Saint-Acheul (1828-30) and at Brieg (Canton Wallis), Switzerland. He returned in 1835 to France, where he was for five years head of the Jesuit establishment at Bordeaux. In 1837 he took the place of Lacordaire (q.v.) at Notre Dame, and continued the "conferences" there until 1846. He spoke with much simplicity, but with intense conviction. Crowds flocked to hear him, the cathedral being, it is said, often filled hours before the sermon began. He has been considered one of the greatest preachers of his time. Among his writings were 'De l'Existence et de l'Institut des Jésuites' (1844; 7th ed., 1855); and 'Clément XIII et Clément XIV' (1854). Consult the sketches by Poujoulat (1858) and Ponlevoy (1860, 13th French ed., 1890; Eng. trans. 1873).

RAVINE-DEER, the name among East Indian sportsmen of the common gazelle of India (*Gazella bennetti*), which is numerous in open rocky places and on the plains from central India to Persia; known also as the dui kara, goat antelope and kalsiefie or black-tail. See GAZELLE.

RAVOGLI, Augustus, American surgeon: b. Rome, Italy, 7 Feb. 1851. He was graduated from the University of Rome in 1873, studied medicine at Vienna, Prague and Berlin, served as surgeon in the Italian army with the rank of major and came to the United States in 1880. He settled in Cincinnati, Ohio, in 1881 and shortly after became professor of dermatology and syphilography at the University of Cincinnati. He has published numerous scientific articles and 'The Hygiene of the Skin' (1888), and 'Syphilis in its Medical, Medicolegal and Sociological Aspects' (1907).

RAWAL PINDI, rá'ûl pin'dê, India, in the Punjab, (1), the administrative capital of the division and district of its own name between the Indus and Jhilam, on the railway from Lahore to Peshawar. It is modern in appearance, well-built and an important grain market. There are an arsenal, a fort, a fine public park, several European churches and the headquarters of the Punjab Northern State Railroad. Transit trade is carried on with Cashmere and Afghanistan. The Sikhs surrendered here after their defeat at Gujrat in 1849, and in 1885 a great durbar or review was held during which the queen of Afghanistan and Lord Dufferin, then governor-general of India, met in an important conference. Pop. 86,483. (2) The Rawal Pindi division comprises four districts with a total area of 15,435 square miles. The district contains many towns connected with the campaign of Alexander the Great. Pop. 4,212,794.

RAWDON, Francis. See HASTINGS, FRANCIS RAWDON.

RAWHIDE, a form of leather in which the curing process stops short of destroying the life of the material. The result is a material remarkable for toughness, durability, tensile strength and pliancy. It is used for belting rope, hydraulic packing, laces of various kinds, pinion wheels, washers, harness, mauls and mallets, trunks, saddles, artificial limbs, whips, lariats, etc.

RAWLE, râ, Francis, American lawyer: b. Freedom Forge, Pa., 7 Aug. 1846. He was graduated at Harvard in 1869, studied law there and in 1871 was admitted to the bar. He was treasurer of the American Bar Association in 1878-1902, and presided in 1902-03; and was overseer of Harvard in 1890-1902. He is author of articles contributed to legal journals and edited Bouvier's 'Law Dictionary' (eds., 1883, 1898, 1913).

RAWLE, William, American lawyer: b. Philadelphia, Pa., 28 April 1759; d. there, 12 April 1836. He studied law in New York and in London, was admitted to the Pennsylvania bar in 1783, in 1791 was appointed by Washington as district attorney of Pennsylvania, and in 1794 assisted in the prosecution of the offenders in the Whisky Rebellion. He acted as counsel for the United States Bank for many years, was chancellor of the Associated Members of the Bar of Philadelphia, and of the Law Association of that city and was a trustee of the University of Pennsylvania from 1796 until his death. He assisted in the revision of the civil code of Pennsylvania in 1830, was one of the founders of the Historical Society of Pennsylvania in 1824, serving as its first president and was also president of the Abolition Society. His publications include 'A View of the Constitution of the United States' (1825); 'Discourse on the Nature and Study of the Law' (1832); 'A vindication of the Rev. Mr. Heckewelder's 'History of the Indian Nations''; 'Biographical Sketch of Sir William Keith'; 'A Sketch of the Life of Thomas Mifflin'; and a translation from the Greek of Plato's 'Phædo.' He left in manuscript an 'Essay on Angelic Influences,' and a dissertation on 'The Evidences of Christianity.' Consult Wharton, 'Mémorial of William Rawle' (1840).

RAWLE, William Henry, American lawyer: b. Philadelphia, 31 Aug. 1823; d. 19 April 1889. He was graduated at the University of Pennsylvania in 1841 and three years later was admitted to the bar, where he rapidly attained prominence. He enlisted in the Union army during the Civil War (1861) and re-enlisted in 1863, then serving as quartermaster. He was vice-provost of the Law Academy (1865-73) and vice-chancellor of the Law Association from 1880 to the time of his death. He published 'Law of Covenants for Title' (1852); 'Equity in Pennsylvania' (1868); 'Some Contrasts in the Growth of Pennsylvania in English Law' (1881); 'Oration at Unveiling of the Monument Erected by the Bar of the United States to Chief-Justice Marshall' (1884); and 'The Case of the Educated Unemployed' (1885).

RAWLING, Cecil, English general and explorer: b. 1870; killed in action, 28 Oct. 1917. His early military career was spent in India, where he took part in the North-West Frontier

campaigns of 1897-98. His 'passion for high mountains and the waste places of the earth' led him to surveying work on the Tibetan frontier, where he mapped some 40,000 square miles of territory in 1903 and gained local knowledge that proved valuable in the Tibet Expedition of 1904. With a small party he next explored the northern slopes of the Himalaya and the sources of the Bramaputra, which he traced to its sources. The record of his discovery was published in his book, 'The Great Plateau.' His next undertaking was an expedition to Dutch New Guinea, where, in the course of an adventurous journey, the party discovered a new pigmy race. The outbreak of the European War prevented him from carrying out a bold plan to attempt the ascent of Mount Everest from the Tibetan side. He raised a battalion himself and fought on the Western Front at Hooge, Ypres and at the Somme. The Royal Geographical Society awarded him the gold medal (June 1917) for his exploring work. He was killed by a stray shell.

RAWLINS, râ'lînz, John Aaron, American military officer: b. East Galena, Ill., 13 Feb. 1831; d. Washington, D. C., 9 Sept. 1869. He took up the study of law and in 1854 began practice in his native town. In 1861, soon after the storming of Fort Sumter, he made a brilliant war speech at a meeting presided over by Ulysses S. Grant, who was so greatly impressed that he requested Rawlins to act as his assistant adjutant-general. He then entered the army and throughout the war was Grant's closest friend and adviser. He took an active part in the campaigns of 1862-63, and was appointed brevet major-general, 13 March 1865. He was a man of marked ability as a soldier, although he never had military training. General Sherman said that Rawlins 'was an intense thinker and a man of vehement expressions, a soldier by force of circumstances rather than of education or practice, yet of infinite use to his chief throughout the war and up to the time of his death.' He was Secretary of War during Grant's first administration.

RAWLINS, Joseph Lafayette, American legislator: b. Salt Lake County, Utah, 28 March 1850. He received a classical education at the University of Indiana, but was not graduated and was a professor at the University of Deseret in Salt Lake City 1873-75. He was admitted to the bar in 1875 and practised until 1892, when he was a successful candidate for Delegate in Congress. Defeated for a second term in 1895 he was elected to the United States Senate in 1897, where he served till 1903, and was a member of the committees on Foreign Relations, Immigration, Geological Survey, Indian Affairs, Pacific Railroads, Public Buildings and Grounds and the Philippines.

RAWLINS, Wyo., city, county-seat of Carbon County, on the Union Pacific Railroad, about 135 miles west by north of Laramie. It is the commercial centre of an extensive stock-raising and mineral region. Its manufactures are chiefly for local use; but the railroad shops give employment to a number of persons. It ships annually a large amount of minerals, sheep, wool and live cattle. The State Penitentiary is at Rawlins. Pop. 4,256.

RAWLINSON, rà'lin-sòn, George, English Orientalist: b. Chadlington, Oxfordshire, 23 Nov. 1815; d. London, 6 Oct. 1902. Educated at Oxford, he took orders and was made a Fellow and Tutor of Exeter College in 1840. In 1845 he became sub-rector, delivered the Bampton lectures in 1859, and in 1861 was made Camden professor of ancient history. He received from Mr. Gladstone a canonry of Canterbury Cathedral in 1872, and in 1888 accepted the living of All Hallows, Lombard Street, London. An indistinct utterance interfered with his public speaking and his pulpit was mainly filled by proxy. His learning was large and various and his services to biblical scholarship of the highest importance. With his brother, Sir Henry Rawlinson (q.v.), and Sir George Wilkinson he published an annotated edition of Herodotus (1850-60). Among his other works are 'The Historical Evidences of the Truth of Scripture Records' (1860); 'The Five Great Monarchies of the Ancient World' (1862-67); 'Historical Illustrations of the Old Testament' (1871); 'The Sixth Great Oriental Monarchy, or the Geography, History and Antiquities of Parthia' (1873); 'The Seventh Great Monarchy' (Persian Empire) (1876); 'The Origin of Nations' (1877); 'Saint Paul in Damascus and Arabia' (1877); 'History of Ancient Egypt' (1881); 'Religions of the Ancient World' (1882); 'The Antiquity of Man Historically Considered' (1882); 'The Early Prevalence of Monotheistic Beliefs' (1883); 'Egypt and Babylon from Scripture and Profane Sources' (1884); 'Religious Teachings of the Sublime and Beautiful in Nature' (1884); 'Ancient History' (1887); 'Ancient Egypt' (1887); 'Moses: His Life and Times' (1887); 'A History of Phœnicia' (1889); 'The Kings of Israel and Judah' (1889); 'Isaac and Jacob: Their Lives and Times' (1890); 'Parthia' (1893); 'A Memoir of Major-General Sir Henry Creswicke Rawlinson' (1898); and others in the department of biblical commentary.

RAWLINSON, SIR Henry Creswicke, English diplomatist and Orientalist: b. Chadlington, Oxfordshire, 4 Nov. 1810; d. London, 5 March 1895. He went to Bombay in 1827 as a military cadet in the service of the East India Company, at once applied himself assiduously to the study of the Oriental languages and was soon in request as an interpreter. After five years' service with the First Bombay Grenadiers, he was employed in military work in Persia (1833-39). When the rupture with Persia compelled the withdrawal of British officers from that country he proceeded to Afghanistan and in June 1840 was appointed political agent at Kandahar. Throughout the troubles that ensued he held the southern capital of the Afghans safe from all intrigues within and attacks without. In 1843 he was appointed political agent in Turkish Arabia. His stay in Persia had made him acquainted with the cuneiform inscriptions at Behistun and on being appointed in 1844 consul at Badgad, he set himself to copy and decipher the chief inscription. The result was his great paper on 'The Persian Cuneiform Inscription at Behistun,' printed in the *Journal of the Royal Asiatic Society* in 1846. Though not without important predecessors in the same field, Rawlinson is justly regarded as the chief founder of

the study of Persian cuneiform and the first successful decipherer of cuneiform writings. Having shown great zeal and ability in the discharge of political duties, he was raised in 1851 to the rank of consul-general. Resigning in 1855, he returned to England and in 1856 was created K.C.B., promoted lieutenant-colonel and appointed a crown director of the East India Company. In 1858 he was elected to the House of Commons for Reigate as a conservative and again sat there in 1865-68 as a member for Frome. In 1859-60 he was minister-plenipotentiary at Teheran, in 1889 became a G.C.B., and two years later was created a baronet. Rawlinson received many honors both at home and from foreign countries. He was president of the Royal Asiatic Society in 1878-81 and of the Royal Geographical Society in 1871-72 and 1874-75. His chief published works are 'A Commentary on the Cuneiform Inscriptions of Babylon and Assyria' (1850); 'Cuneiform Inscriptions of Western Asia' (1861-80; 2d ed. of Vol. I, 1891), with Norris, E., Smith, G. and Pinches, T. G.; 'England and Russia in the East' (1875), a strongly anti-Russian pamphlet; notes in the translation of 'Herodotus' by his brother, George Rawlinson (q.v.), and many papers in the journals of the Royal Asiatic and Royal Geographical Societies. See the 'Life' by his brother (1898), with an introduction by Earl Roberts.

RAWNSLEY, rànz'li, Hardwicke Drummond, English Anglican clergyman and poet: b. Henley-on-Thames 28 Sept. 1851. He was educated at Oxford, took orders in 1875, was vicar of Wray, Windermere, 1878-83, and has been vicar of Crosthwaite, Keswick, from the last-named date. Among his many published works are 'Sonnets Round the Coast'; 'Sonnets at the English Lakes'; 'Literary Associations of the English Lakes'; 'Village Sermons'; 'Sonnets in Switzerland and Italy' (1899); 'Memories of the Tennysons' (1900); 'Ruskin and the English Lakes' (1901); 'A Rambler's Note Book at the Lakes' (1902); 'Sketches at the English Lakes' (1903); 'Flower-time in the Oberland' (1904); 'The Sacrum commercium of Saint Francis' (1904); 'Sermons on the Sayings of Jesus, from the Oxyrhyncus Papyri' (1905); 'A Sonnet Chronicle, 1900-05' (1906); 'The European War: Poems' (1915); 'Past and Present at the English Lakes' (1916).

RAWSON, rà'sòn, Albert Leighton, American author and artist: b. Chester, Vt., 15 Oct. 1829; d. New York, November 1902. He studied law, theology and art and traveled extensively in the Orient, later exploring the Indian mounds in the Mississippi Valley, and traveling in Central America and in the Hudson Bay territories. He founded the Theosophical Society in the United States, was adopted into the tribe of the Adwan Bedouins of Moab and initiated by the Druses in Mount Lebanon. His books, illustrated by his own maps and drawings, include 'Bible Dictionaries' (1870-75); 'Histories of All Religions' (1870); 'Antiquities of the Orient' (1870); 'Vocabulary of the Bedawin Languages of Syria and Egypt' (1874); 'Chorography of Palestine' (1880); 'Historical and Archaeological Introduction to the Holy Bible' (1884); 'The Unseen World' (1888); 'History of Mysticism'; etc. He illustrated Rev. Dr.

Charles F. Deems's 'Jesus' (1868), and Rev. Henry Ward Beecher's 'The Life of Jesus' (1871). At the time of his death he was completing an elaborate history of Freemasonry. His priceless collection of manuscripts, sketches, photographs and various art treasures were destroyed by fire in 1893.

RAWSON, Edward Kirk, American educator: b. Albany, N. Y., 21 Feb. 1846. He was graduated from Yale in 1868, from Andover Theological Seminary in 1872, and was ordained in the Congregationalist ministry. In 1871-90 he was chaplain in the United States navy, serving at the Naval Academy from 1886, and in 1888-90 professor of ethics and English there. In 1897-1902 he was superintendent of naval war records; in 1902-08, head of the department of English and law at the Naval Academy; in latter year retired. He published 'Twenty Famous Naval Battles: Salamis to Santiago' (1899).

RAY, Anna Chapin, American author of juvenile fiction: b. Westfield, Mass., 3 Jan. 1865. She was graduated at Smith College 1885; received the degree of A.M. in 1888, and removed to Quebec, Canada, in 1903. She published 'Half a Dozen Boys' (1890); 'Half a Dozen Girls' (1891); 'In Blue Creek Cañon' (1892); 'Dick' (1896); series of six 'Teddy' books (1898-1904); 'Each Life Unfulfilled' (1899); 'Bumper and Baby John' (1903); 'The Dominant Strain' (1903); 'By the Good Sainte Anne' (1905); series of six 'Sidney' books (1905-10); 'The Bridge Builders' (1909); 'A Woman with a Purpose' (1911); three 'Buddie' books (1911-13), etc.

RAY, George Washington, American jurist: b. Otselec, Chenango County, N. Y., 3 Feb. 1844. He was educated at Norwich Academy; served in the Civil War as private and brigade clerk; was admitted to the bar and began practice at Norwich, N. Y., in 1867. He was a representative in Congress in 1883-85 and 1891-92, resigning in the latter year to become United States district judge in the Northern District of New York. He opposed the free silver bill of 1892, was chairman of the committee on invalid pensions and of the committee on judiciary.

RAY, Isaac, American physician: b. Beverly, Mass., 16 Jan. 1807; d. Philadelphia, Pa., 31 March 1881. He was graduated from Bowdoin in 1827, practised medicine, and in 1841-45 was superintendent of the State insane asylum at Augusta, Maine. In 1845-66 he had charge of the Butler Hospital for the Insane at Providence, R. I., and then removed to Philadelphia, where he engaged in medical practice. He published 'Conversations on Animal Anatomy' (1829); 'Medical Jurisprudence of Insanity' (1838); 'Education in Relation to the Health of the Brain' (1851); 'Mental Hygiene' (1863); 'Contributions to Mental Pathology' (1873), etc.

RAY, John (at an earlier period spelled by him WRAY), English naturalist: b. Black Notley, near Braintree, Essex, 29 Nov. 1627; d. there, 17 Jan. 1705. He was educated at Trinity College, Cambridge, was made Greek lecturer in 1651; mathematical lecturer in 1653; humanity reader in 1655 and junior dean in 1658. He made long botanical and zoological tours in

England, Scotland and Wales, and in 1663-66 traveled about Europe with Francis Willoughby in an attempt to accomplish a systematic description of the entire organic world. It is thought that much of the credit bestowed on Ray as the founder of English natural history should properly attach to Willoughby. Ray was elected F.R.S. in 1667. Among his works are 'Catalogus Plantarum Angliæ' (1670), the basis of all subsequent English floræ; 'Methodus Plantarum Nova' (1682), giving a new system of classification; 'Historia Plantarum' (1686-1704); 'Synopsis Methodica Animalium Quadrupedum et Serpentine Generis' (1693), and three posthumous volumes on birds, fishes and insects. He also arranged and classified Willoughby's collection of materials for an extensive work on the animal kingdom, published under the titles of 'Ornithologia' (1676) and 'Historia Piscium' (2 vols. 1686). These volumes noted many species of birds and fishes not observed by previous naturalists. In 1844 The Ray Society was founded at London for the publication of scientific works of established merit. Consult the 'Memorials' by Lankester (1844).

RAY, a group of elasmobranchs forming the suborder *Batoidei*. The skates and the rays are nearly allied to each other, and are recognized by their broad flattened bodies, which are generally of a rhomboidal shape, and consist in greater part of the enormously developed pectoral or breast fins, which are supported upon a modified portion of the anterior skeleton. On the upper surface of the disc-like body the eyes are borne, together with spiracles or apertures, by which water may be admitted to the gill-sacs. The mouth, nostrils and gill-openings (five on each side) are in the lower surface of the body. The mouth is generally furnished with broad flat teeth of rhomboidal shape, and is of small size. The tail is elongated and slender, and is generally armed with sharp spinous processes. (See STING-RAY). Two or more dorsal fins may exist, whilst the caudal or tail fin is heterocercal. These fishes produce eggs, which, like those of sharks, are enclosed in cartilaginous capsules, known as "mermaids' purses," etc. Occasionally the rays may attain very large dimensions and weights. They are bottom-fishes, and feed upon other small fishes, crustaceans and mollusks. They swim chiefly by peculiar undulating motions of the edges of the pectoral fins. In the true rays (*Rajidae*) the snout is more or less pointed and prolonged, and two dorsal fins exist near the end of the tail. The most common members of this group are the sting-rays (q.v.). The European sharp-nosed ray (*R. oxyrinchus*) is a favorite French food-fish; the homely ray (*R. maculata*), also, is frequently sold in the London markets. The American species are called skates (q.v.). The eagle rays (*Myliobatidae*) possess projecting heads, with the pectoral fins extended laterally in a great degree so as to imitate wings. The teeth are hexagonal, flat and pavement-like. The slender tail possesses one dorsal fin and is armed with a notched spine. These include the California "batfish" (*Myliobatis californicus*), and a famous whip-tailed species of the Mediterranean (*M. aquila*). Allied to these are the huge blanket-rays (*Mantida*), so much dreaded by swimmers and

divers in all warm seas. Specimens weighing more than 1,000 pounds have been taken in the Mediterranean. (See DEVILFISH.) Other families are the sawfishes (*Pristidae*), the guitarfishes (*Rhinobatidae*) and the electric rays or torpedoes (*Narcobatidae*), elsewhere described. See FISHES; ICHTHYOLOGY.

RAYAHS, rā'yāz, the Christian peasantry, laborers and small farmers who lived under Turkish rule in the Balkan peninsula. The word means "cattle," and as cattle these people were treated by their Turkish masters in Bosnia, Servia, Bulgaria and the neighboring states. The term is also applied in Turkey to non-Mohammedan subjects who pay the haratch or capitation tax.

RAYLEIGH, rā'li, John William Strutt, BARON, O. M., English physicist: b. 12 Nov. 1842; d. 30 June 1919. He was educated at Cambridge, became a Fellow of Trinity College in 1866 and succeeded as 3d Baron Rayleigh in 1873. From 1879 till 1884 he was professor of experimental physics at Cambridge; from 1887 to 1905 was professor of natural philosophy in the Royal Institution; from 1887 till 1896 was secretary to the Royal Society and the latter year scientific adviser to Trinity House. Beside contributions to the proceedings of scientific societies, he contributed the articles "Optics" in the 'Encyclopædia Britannica' (9th edition) and 'The Theory of Sound' (1877-78; new ed. 1894-96). He also edited Maxwell's 'Heat' (1891-94). He was associated with Prof. William Ramsay in the latter's discovery, in July 1894, in atmospheric nitrogen of a new gas, called by them argon, for which in 1904 he was awarded the Nobel prize in physics. He became lord chancellor of Cambridge University in 1908. His work was the most productive in chemical physics, theory of gases, flow of liquids, photography, optics, color vision, wave theory and in electric and magnetic problems of all kinds.

RAYMOND VI, rā'mōnd, count of Toulouse: b. 1156; d. 1222. He succeeded to the territory in 1194. He protected the Albigenses, against whom Pope Innocent III sent an army in 1208 to avenge the assassination of his legate. Raymond's territories were ravaged, he himself twice excommunicated, 1208 and 1211, and his lands given over to Simon de Montfort. After the death of de Montfort at the siege of Toulouse in 1218 Raymond recovered his territories, but again espousing the cause of the Albigenses he was once more excommunicated.

RAYMOND VII, son of Raymond VI and last count of Toulouse: b. 1197; d. 1242. He engaged with his father for the recovery of Toulouse from Simon de Montfort, and finally forced the latter's son Amalric to a complete surrender. Forced to make peace with the Pope and King Louis IX of France in 1229, he ceded Narbonne and other territory to France and made Alphonse, Count of Poitiers, brother-in-law of the king and the husband of his only daughter Jeanne, heir to the remainder of his estate.

RAYMOND, Andrew Van Vranken, American clergyman: b. Visscher's Ferry, N. Y., 8 Aug. 1854. He was graduated at Union College 1875, and at the New Brunswick Theological Seminary 1878. He was pastor of the

First Reformed Church, Paterson, N. J., 1878-81; Trinity Reformed Church, Plainfield, N. J., 1881-87, and of the Fourth Presbyterian Church, Albany, N. Y., 1887-94; president of Union College, Schenectady, N. Y., 1894-1907, and pastor of the First Presbyterian Church, Buffalo, N. Y., from 1 July 1907.

RAYMOND, Bradford Paul, American educator: b. Stamford, Conn., 22 April 1846; d. Middletown, Conn., 27 Feb. 1916. He was graduated from the Theological School of Boston University in 1873, ordained to the Methodist Episcopal ministry in 1874, and studied in Germany in 1880-81. He held successive pastorates in New Bedford, Mass., Providence, R. I., and in Nashua, N. H., was president of Lawrence University, Appleton, Wis., in 1883-89; president of Wesleyan University, Middletown, Conn., in 1889-1908, and professor of ethics and biblical literature there from 1909. He published 'Christianity and the Christ.'

RAYMOND, Evelyn Hunt, American writer of juvenile fiction: b. Watertown, N. Y., 6 Nov. 1843; d. Baltimore, Md., 18 April 1910. She was educated at Mount Holyoke College, and was married to John B. Raymond in 1869. Among her many popular books may be cited 'Mixed Pickles' (1892); 'A Cape May Diamond' (1896); 'Little Red Schoolhouse' (1897); 'A Daughter of the West' (1899); 'Reels and Spindles' (1900); 'The Sun Maid' (1900); 'A Daughter of the Forest' (1902); 'Polly the Gringo' (1905); 'The Heroine of Roseland' (1907); 'Carlota of the Rancho' (1909), and the 'Jessica Trent' series (2 vols.), and the 'Dorothy' series (6 vols., 1907-10).

RAYMOND, George Lansing, American educator: b. Chicago, Ill., 3 Sept. 1839. He was graduated from Williams College in 1862 and from Princeton Theological Seminary in 1865. After spending three years in Europe he entered the Presbyterian ministry and was pastor at Darby, Pa., 1870-74; professor of oratory at Williams 1874-80; professor of oratory and æsthetic criticism at Princeton 1880-93, of æsthetics at Princeton 1893-1905, and at George Washington University 1905-12. Among his many published works in verse and prose are 'Life in Song' (1886); 'Poetry as a Representative Art' (1886); 'Ballads of the Revolution' (1887); 'The Representative Significance of Form' (1900); 'The Aztec God and Other Dramas' (1900); 'The Essentials of Æsthetics' (1907); 'Psychology of Inspiration' (1908); 'Fundamentals in Education, Art and Civics' (1911); 'Suggestions for the Spiritual Life' (1912); 'An Art Philosopher's Cabinet' (1915).

RAYMOND, Henry Jarvis, American journalist: b. Lima, N. Y., 24 Jan. 1820; d. New York, 18 June 1869. He was graduated from the University of Vermont in 1840, went to New York, studied law, and contributed to 'The New Yorker', a literary weekly published by Horace Greeley. Upon the establishment of the 'New York Tribune' in 1841 he became assistant editor. While editorially connected with the 'Courier and Enquirer' (1843-51) he engaged with Greeley in a spirited controversy on the subject of Fourierism, which had at that time taken a strong hold upon the American people resulting in the establishment of communities more or less resembling Brook Farm.

He was elected to the State assembly in 1849 and 1850, the latter year becoming speaker. In 1851 he established the *New York Times*, the first number being issued on 18 September. In 1854 he was elected lieutenant-governor of the State. He was one of the prominent organizers of the Republican party, and drew up the "Address to the People," promulgated by its first national convention held in Pittsburgh February 1856. His choice for President in 1860 was William H. Seward, and he used his influence to place him in the Cabinet after Lincoln's election. After the disaster at Bull Run he proposed a provisional government, feeling that Lincoln's policy was too hesitating. He was again member of the assembly in 1861, where he was chosen speaker; and in 1864 was elected to Congress, giving his support to President Johnson's policy. He was the author of the "Philadelphia Address" to the people of the United States, promulgated by the National Union Convention, which he helped to organize in 1866. He was an effective public speaker and exerted a marked influence on the elevation of the tone of journalism. He wrote 'Political Lessons of the Revolution' (1854); 'Letters to Mr. Yancy' (1860); 'History of the Administration of President Lincoln' (1864); 'Life and Services of Abraham Lincoln' (1865). Consult Maverick, 'Henry J. Raymond and the New York Press for Thirty Years' (1870).

RAYMOND, John Howard, American educator: b. New York, 7 March 1814; d. Poughkeepsie, 14 Aug. 1878. He was graduated at Union College in 1832; studied law in New Haven; entered the theological seminary at Hamilton, N. Y., in preparation for the Baptist ministry in 1834; was appointed tutor in Hebrew before graduation; became professor of rhetoric and English literature at Madison University in 1839, and removed to the newly established Rochester University as professor of belles-lettres in 1850. As an organizer of educational institutions he showed remarkable aptitude, performing that service for the Collegiate and Polytechnic Institute in Brooklyn in 1856 and for Vassar College in 1865. He filled the post of president and professor of mental and moral science at Vassar until his death. Consult his 'Life and Letters' (1880).

RAYMOND, John T., American actor: b. Buffalo, N. Y., 5 April 1836; d. Evansville, Ind., 10 April 1887. His original name was John O'Brien. His first appearance was at Rochester in June 1853, as Lopez in 'The Honeymoon.' In 1861 he made a great hit as Asa Trenchard in 'Our American Cousin,' and in 1867 went to England and appeared in this character in the company of E. A. Sothorn, who was the famous Lord Dundreary. In 1874 he achieved his greatest success as Colonel Mulberry Sellers in a dramatization of Mark Twain's 'Gilded Age.' He was widely popular and depicted certain types of broad, humorous character with great success.

RAYMOND, Miner, American Methodist Episcopal clergyman: b. New York, 29 Aug. 1811; d. Evanston, Ill., 25 Nov. 1897. He was graduated at Wesleyan Academy, Wilbraham, Mass., in 1831, and was a member of the faculty there in 1831-41. After holding pastorates at Worcester, Boston and Westfield he returned to Wesleyan Academy and was its principal

in 1848-64. He became professor of systematic theology at Garrett Biblical Institute, Northwestern University, Evanston, Ill., in 1864 and remained in that position 30 years. Author of 'Systematic Theology' (3 vols., 1877).

RAYMOND, Rossiter Worthington, American mining engineer: b. Cincinnati, Ohio, 27 April 1840; d. Brooklyn, N. Y., 31 Dec. 1918. He was graduated from the Brooklyn Polytechnic Institute in 1858 and spent three years in study at Freiburg, Munich and Heidelberg. Returning from Europe he entered the Union army and served from 1861 to 1864 as additional aide-de-camp with the rank of captain. From 1864 to 1868 he was consulting engineer in New York, at the end of which time he was appointed United States commissioner of mining statistics and held this post until 1876. From 1870 to 1882 he was lecturer on economic geology at Lafayette College. In 1885-88 he was New York State commissioner of electric subways for the city of Brooklyn. One of the original members of the American Institute of Mining Engineers, he became its vice-president in 1871, was its president 1872-74, secretary 1884-1911, and secretary emeritus from 1911. He was a member of scientific and technical societies in Europe and America, including the Society of Civil Engineers of France. In 1903 he became lecturer on mining law in Columbia University. He published 'Reports on the Mineral Resources West of the Rocky Mountains' (1869-76); 'The United States Mining Industry'; 'Mines, Mills and Furnaces'; 'Silver and Gold'; 'Brave Hearts,' a novel (1873); 'The Man in the Moon and Other People' (1874); 'The Book of Job' (1878); 'Camp and Cabin' (1880); 'A Glossary of Mining and Metallurgical Terms' (1881); 'Memorial of Alexander L. Holly' (1883); 'Life of Peter Cooper' (1901); also technical works and papers, especially on mining law.

RAYMOND, Walter, English novelist: b. Yeovil, Somerset, 13 March 1852. He was educated at private schools, and was partner in a glove manufactory, but in 1895 gave up business for literature. Among his works, several of which appeared under the pseudonym "Tom Cobbleigh" are 'Misterton's Mistake' (1890); 'Gentleman Upcott's Daughter' (1894); 'Love and Quiet Life' (1894); 'Tryphena in Love' (1895); 'Two Men o' Mendip' (1898); 'The Idler Out of Doors' (1901); 'Jacob and John' (1905); 'The Book of Simple Delights' (1906); 'Tales from Gossip-Corner' (1907).

RAYMOND, William Galt, American civil engineer: b. Princeton, Iowa, 2 March 1859. He was graduated at Washington University as a civil engineer in 1884; was instructor of civil engineering at the California State University 1884-90; was professor of geodesy, road engineering and topographical drawing at the Rensselaer Polytechnic Institute 1892-1904, and since 1904 professor of civil engineering and director of the School of Applied Sciences at Iowa State University. He published 'Plane Surveying' (1896); 'Elements of Railroad Engineering' (1908); 'Railroad Field Geometry' (1910); 'Railroad Field Manual for Civil Engineers' (1915).

RAYMOND, Battle of. After the battle of Port Gibson (q.v.), 1 May 1863, the Con-

federates fell back beyond the Bayou Pierre and destroyed the bridges. General Grant followed on the 2d, occupied Port Gibson, and the same evening the Confederates continued their retreat across Big Black River, at Hankinson's Ferry, leaving a force behind to prevent the crossing, which was attacked on the morning of the 3d by Crocker's division of McPherson's corps. The Confederates stoutly contested the ground, retiring very slowly, until late in the day, when Logan's division came upon their flank, when they hastily crossed the river. McPherson's corps was moved forward to Hankinson's Ferry and McClelland's to Willow Springs, where they remained until the 7th, when, Sherman's corps having crossed the Mississippi, the advance was resumed, the main body of the army moving along the line of the Big Black toward Edwards' Station, midway between Vicksburg and Jackson, while McPherson, on the right, was directed upon Jackson, the capital of the State, 45 miles east of Vicksburg, and the geographical and railway centre of the State. On the night of the 11th McPherson bivouacked five miles northeast of Utica, on the road to Raymond, and early in the morning pushed rapidly for Raymond, 18 miles from Jackson, hoping to capture some commissary stores, but before 9 A.M. Logan's division, in the advance, encountered a strong body of the enemy, upon which the division was deployed and continued its advance for two hours, when, coming to a small stream crossing the road about two miles from Raymond, General Gregg's brigade of about 3,000 men, with two batteries, was seen beyond the stream, disposed to enfilade the road and bridge over the stream. Logan threw out skirmishers and advanced, bringing on a severe engagement which continued more than two hours, when the leading brigade of Crocker's division came up to his support, upon which Gregg, leaving two disabled guns, abandoned the field and retreated toward Jackson, being joined on the way by Walker's brigade, and when overtaken by night, bivouacking five miles from the field. The Union loss was 66 killed, 339 wounded and 37 missing. Gregg reported a loss of 73 killed, 229 wounded and 204 missing. Consult 'Official Records,' Vol. XXIV; Grant, 'Personal Memoirs,' Vol. II.

E. A. CARMAN.

RAYNAUD'S (rā-nōz') **DISEASE**, a vasomotor affection, occurring mostly in children and young adults, and characterized by coldness and whiteness of the toes, the tips of the fingers, the end of the nose and sometimes of the lobes of the ears. It may exist with other functional nervous disorders, such as hysteria and neuralgia, and occurs especially in persons of neurotic heredity or temperament. It was first studied by Raynaud in 1862. He believed that the local manifestations are due to constrictor spasm, probably originating in the gray centres of the spinal cord. No central lesions have been found. After exposure to cold, the toes, fingers, nose, etc., become cold, numb and white (local syncope), and pricking draws no blood. When warmth and color return, there is frequently pain, also congestion, swelling and a purple color (local asphyxia). Either of these stages may be recovered from, or the second stage may end in gangrene of the parts (Ray-

naud's gangrene, local or symmetrical gangrene). Recurrences of the disease are common. The prognosis is not good, especially in debilitated children. For treatment avoid cold, use warm baths, electricity and massage. Ichthyol ointment sometimes alleviates the pain. Other remedies should be advised by the physician.

RAYNER, rā'ner, **Emma**, American novelist: b. Cambridge, England. She was graduated from Cambridge University in 1888, came to this country and was employed on the staff of the *Youth's Companion* in 1896-1902. She published 'Free to Serve' (1897); 'In Castle and Colony' (1899); 'Visiting the Sin' (1900); 'Doris Kingsley: Child and Colonist' (1901); 'Handicapped Among the Free' (1903); 'The Dilemma of Engeltie' (1911).

RAYNER, Isidor, American lawyer and politician: b. Baltimore, Md., 11 April 1850; d. Washington, D. C., 25 Nov. 1912. He received his education at the University of Virginia, and entering on the practice of law in 1870, soon became one of the leaders of the Baltimore bar. In 1878 he was elected to the State legislature for two years, in 1885 was chosen a State senator for four years, but resigned in the middle of his term to become the Democratic candidate for Congress, in which he served in 1887-89 and 1891-95. In 1899-1903 he was attorney-general of Maryland, and from 1905 till his death, United States Senator. In early youth he practised declamation and became an effective speaker.

RAYNOUARD, rā-noo-ār, **François Juste Marie**, French poet and philologist: b. Brignoles, department of Var, 18 Sept. 1761; d. Passy, 27 Oct. 1836. He studied for the bar at Aix and practised law at Draguignan with great success. Elected a deputy to the legislative assembly in 1791, he attached himself to the Girondins, and on the proscription of that party was thrown into prison. The fall of Robespierre set him at liberty, whereupon he resumed his profession of advocate in his native province and acquired a fortune. Having previously made two unsuccessful attempts to live by his pen, he once more settled in Paris. His poems 'La vertu nécessaire dans les républiques' (1803) and 'Socrate dans le Temple d'Aglaure' (1804), obtained prizes from the French Academy. These were followed by two tragedies, 'Eléonore de Bavière' and 'Les Templiers,' the latter performed at the Théâtre Français in 1805 by order of Napoleon. In 1806 he was elected a member of the Corps Législatif. In 1817 he was nominated perpetual secretary of the Academy, a post he resigned in 1826, when the ministry presented to the chambers a bill which had for its object the limiting of the liberty of the press. Of most value to the world is the work in the field of Romance philology, his writings including 'Grammaire comparée des Langues de l'Europe Latine dans leurs Rapports avec la Langue des Troubadours' (1821); 'Choix des Poésies originales des Troubadours' (1816-21); 'Lexique Roman ou Dictionnaire de la Langue des Troubadours comparée aux autres Langues de l'Europe Latine' (posthumous, 1838-44); 'Observations Philologiques sur le Roman de Rou, et sur quelques Règles de la Langue des Trouvères au XIIe Siècle' (1829).

RAZIN, ră'zën, **Stenko**, Russian bandit: d. Moscow, 1671. He was the leader of Cossacks who plundered caravans and fisheries along the Volga. Being captured he was pardoned by Alexis, but rebelled again, and gathered about himself the dissatisfied elements, captured cities and ruled along the Volga as far as Nijni-Novgorod. He was finally taken and executed at Moscow. Thereupon he became the hero of epic song of the 17th century and was regarded as the champion of the people against the nobles.

RAZOR, the well-known keen-edged instrument for shaving off the beard or hair. Razors seem to have been in use at a very early period of the world's history. They were used by the ancient Egyptians. The Levitical code expressly forbade the shaving of the beard, and many Jews in some countries remove all superfluous hair with the scissors until this day. It is believed by many authorities that the primitive shaving-instruments were made of sharpened flints; the savages of Polynesia still use two pieces of flint of the same size, or pieces of shells or sharks' teeth ground to a fine edge, for this purpose. Among civilized nations the blade is metal, usually steel, the finest cast steel being preferred. The handles are made of a great variety of materials, as silver, ivory, tortoise-shell, bone, horn, etc. The Chinese and Japanese razors are very rarely furnished with handles. In the United States a modern form, known as a "safety" razor, has become widely popular.

RAZOR-BILL, the *Alca torda*, the sole species of the genus, the *Alca impennis*, or great auk, being extinct. It is intermediate in structure between the guillemots and the great auk; but characterized by its compressed, elevated, hooked and furrowed bill, its peculiar stiff wedge-shaped tail and ample wings. It is about 18 inches long, generally black above and white below; but in the breeding plumage the head and neck become lustrous black all around, with a very characteristic fine white line running from the eye to the base of the bill. This bird is abundant in the North Atlantic, frequenting rocky islands and coasts to breed with puffins and guillemots, but at other seasons keeping farther out at sea, and in winter migrating as far south as the Mediterranean and the coast of New Jersey or even North Carolina. On the American side it breeds in the Bay of Fundy and in great colonies in the Gulf of Saint Lawrence, about Labrador, etc. A single much blotched and streaked whitish egg, about three inches long, is deposited on a ledge or in a fissure of some precipitous rocky cliff. It feeds upon floating refuse or fish, worms, etc., for which it dives or which it pursues in the water, using both wings and feet in swimming. When molested it sometimes fights viciously, at the same time uttering harsh cries. The large eggs are much gathered for food. It is also known as the black-billed auk, the murre, and the tinker.

RAZOR-CLAM, or **RAZOR-FISH**, a bivalve mollusk of the family *Solenida*, known on all sandy shores. The shell is long and narrow, like a razor-handle, and gapes at both ends, the siphons are short, the foot is large and powerful. The shell is handsomely ornamented and in some tropical species is of great

beauty. These mollusks always live buried in the sand in an upright position, leaving only an opening shaped like a keyhole, which corresponds with the two siphon tubes. They are generally found at a depth of one or two feet, and when they make their burrows, as they are often in the habit of doing, among the rocks, not even an iron hook can draw them from their retreat, but they may sometimes be beguiled by pouring salt water on the spot, deceiving them into the impression that the tide has risen and they may begin to feed. They are edible, but rather tough. A familiar and typical species on the eastern coast of the United States is *Ensis americana*. Consult Kingsley, 'Standard Natural History' (Vol. I, 1885).

RAZORBACK, one of the large whales of the genus *Balaenoptera*, called also finbacks and rorquals. (See **FINBACK**; **WHALE**). The *B. musculus*, the common rorqual or razorback, is 60 to 70 feet long, black above and brilliant white below. The *B. rostrata*, or lesser rorqual, resembles the other, but is much smaller. The rorquals are widely distributed and some of them are found in almost every sea. Razorback is also a name for the thin and agile semi-wild hogs which range the woods in the less settled parts of the southern United States.

RE, ră, the sun god, first and most important of Egyptian divinities. Re is supposed to be the son of Neith (q.v.), the goddess of the upper air, and to have had for his wife Mout, the mother of nature. He had for children Athor, the light; Mu, the sunlight; and Mat, spiritual light, and was widely worshipped by the ancient Egyptians, and in course of time every local divinity became identified with Re; thus, Ammon became Ammon-Re; Sobk changed to Sobk-Re. The attempt to unify the personages of mythology under Re and thus erect a monotheism is credited to Amenophis IV of the 18th dynasty. Re is represented, like Horus, with the head of a hawk and bearing the disc of the sun on his head, and was more extensively worshipped than any other Egyptian deity except Osiris.

RE, ră, or **RHÉ**, Île de, France, a small low-lying island three miles distant from the coast of the department of Charente-Inférieure, opposite the city of La Rochelle, from which it is separated by the Pertuis Breton. It is about 18 miles long and three broad and measures 28 square miles. The inhabitants are chiefly engaged in the preparation of salt, producing 32,000 tons annually. The west coast is rocky; on the east side there are some good harbors. Oyster farming has become an important branch of industry, yielding 35,000,000 annually. Wine is made and exported. The chief town, Saint Martin, was fortified by Vauban. Pop. of island about 15,000.

REA, ră, **Samuel**, American railroad president and engineer: b. Hollidaysburg, Pa., 21 Sept. 1855. He entered the engineering department of the Pennsylvania Railroad when 15 years of age, becoming locating and construction engineer on various branches of the road. He was afterward connected with the Pittsburgh and Lake Erie Railroad, and was chief engineer in the construction of the belt line and tunnel under Baltimore for the Baltimore and Ohio Railroad. He returned to the Pennsylvania

Railroad in 1892 and became its president in 1913. He was in charge of the construction of the New York tunnel extension and the station of the Pennsylvania Railroad in New York, for which the University of Pennsylvania conferred upon him the degree of Sc.D. in 1910. He was appointed a member of the executive committee of the special commission on national defense in the United States Railroad Administration in 1917. Author of 'The Railways Terminating in London' (1888).

REACTION, in chemistry, a general term for any chemical change that is brought about by the mutual interaction of two or more substances. Reactions between two primary substances may be conveniently divided into three classes, as follows: (1) Those in which the two substances combine additively, so as to form a single third substance by their union. (2) Those in which one of the primary substances is broken up, the other primary substance combining additively with one or all of its parts, so as to produce one or more new substances. (3) Those in which there is a double decomposition of the two primary substances, the several parts of the first combining with those of the second so as to produce two or more new substances. The first of these is illustrated by the action of oxygen gas upon metallic sodium, the combination taking place additively according to the equation $2\text{Na} + \text{O} = \text{Na}_2\text{O}$. The second is illustrated by the action of chlorine gas upon an excess of methane (CH_4); methyl chloride and hydrochloric acid being formed (upon exposure to diffuse daylight) in accordance with the equation $\text{CH}_4 + 2\text{Cl} = \text{CH}_3\text{Cl} + \text{HCl}$. The third general type of reaction between two primary substances (that, namely, in which there is a double decomposition) may be illustrated by the action of hydrochloric acid upon caustic potash, KOH , as indicated by the equation $\text{KOH} + \text{HCl} = \text{H}_2\text{O} + \text{KCl}$, the products of the reaction being water and chloride of potassium.

Reactions take place with widely varying degrees of intensity. This intensity is known in chemistry as "affinity," and is evidenced by an exhibition of great heat, violent ebullition, explosion and like physical manifestations. These phases are more noticeable when the two combining substances are of different "electricities," that is, one positive and the other negative. Temperature has a decided effect upon the velocity with which chemical reactions take place, and many reactions may be restrained by cold. On the other hand, after a reaction has taken place a sufficient rise in temperature may decompose the new compound into its primary constituents.

In all reactions it is observed that substances combine in certain definite proportions, and these are called their "combining weights," or "constant proportions." The law which is found to obtain in all cases is that the elements combine in the ratios of their combining weights, or in simple multiples of such ratios—the term "combining weight" standing for the smallest relative mass of the element (that is, the smallest number of atoms) in which the element enters into combination with other elements. Thus, 110.34 parts of potassium bromide are required to supply the exact amount of bromine to convert 100 parts of silver into silver

bromide. Conversely, 100 parts of silver combined with chlorine will form 132.845 parts of silver chloride—no more and no less, though a much greater quantity of chlorine may be present.

The subject of chemical reaction is intimately connected with the entire question of chemical constitution, of which much remains to be learned. See the article CHEMISTRY; also CATALYSIS; CHEMICAL AFFINITY; EQUILIBRIUM, CHEMICAL; PERIODIC LAW; VALENCY.

REACTION TIME. One of the cardinal problems of psychophysics is the measurement of the duration of mental processes. The mental processes themselves are always inaccessible to direct temporal measurement, but certain physiological-psychological complexes are easily available. These consist in the entire aggregate of phenomena which occur between the reception of some stimulus and the conscious, voluntary response to the stimulus. The duration of the aggregate is known as the reaction of time and is measured by various types of chronoscope (q.v.). A simple reaction times is one where the response follows directly upon the stimulation. The length of a simple reaction depends on the sense and mode of reaction employed, and on whether the attention is directed toward the stimulus or the reaction. The following table gives an idea of the order of magnitude of reaction times:

	Attention towards stimulus.	Attention toward reaction.
Reaction to light	.270 seconds	.180 seconds
Reaction to sound	.225 seconds	.120 seconds
Reaction to pressure	.210 seconds	.110 seconds

Besides these simple reactions, reaction experiments may be performed which demand a recognition or a discrimination before the subject can press the reaction key. These experiments will require .03 to .05 seconds more than a simple reaction experiment of the same sort with the attention directed toward the stimulus. It may be thought that this is the actual time of the process of recognition. This interpretation is dependent on interpreting the reaction as an ordinary sensory reaction interrupted by an act of discrimination or cognition. This is in all probability an over-simplification of the facts. Reaction-experiments have also been used to determine the duration of an act of choice and of various types of association. In this latter connection they have been used by some investigators to determine the mental content of a subject who is concealing something. Consult James, W., 'Principles of Psychology' (New York 1890); Külpe, 'Outlines of Psychology' (trans. London 1895); Pilzecker, A., 'Die Lehre von der sinnlichen Aufmerksamkeit' (1889); Titchener, 'Experimental Psychology' (New York 1905); 'Text-book of Psychology' (New York 1909-11); Wundt, 'Grundzüge der physiologischen Psychologie' (6th ed., Leipzig 1908-11).

REACTIONS AND REACTION TIMES IN PSYCHOLOGY. Owing to the large place occupied by movement in man's life and the practical importance of knowing the time required in movements in making records in physics and astronomy, much labor has been spent by the psychologist and physiologist in measuring the time used in making different reactions. The first interest in the topic was

aroused when it was found that different men recorded the time at which a star crossed a wire in the telescope differently. Experiment showed that this was in part due to the variation in the time needed to make the recording movement. Later experiments were devoted to measuring the times of other mental processes that were involved in more complex mental and physical operations, with the object of explaining movement in general. All measurements involve determining the time that elapses between some stimulus and a prescribed movement. The times are recorded electrically. The apparatus most frequently employed is a Hipp chronoscope with instruments for giving stimuli and keys to make or break circuits as the movement is completed. The Hipp chronoscope is a clock controlled by the vibration of a fork or metallic tongue which vibrates 1,000 times per second. The hands are so adjusted that an electric magnet will articulate them with the clock work. As the stimulus is shown a circuit is made through the clock which engages the hands in the gears, and they continue to revolve until the movement breaks the circuit. One reads the time elapsed in thousandths of a second (ordinarily designated σ). One distinguishes simple and compound reactions. The simple are made as quickly as possible after the stimulus, the compound are delayed until some mental operation is introduced. The simple reaction varies in length with the individual and with the mental attitude. If one attends to the movement alone the response is quicker than if one attends to the stimulus and makes sure that one knows what it is before one acts. The latter or sensory times for auditory stimuli range from 180σ to 220σ ; for visual stimuli from 200σ to 290σ , and for tactual stimuli are about 210σ . The muscular reactions require about 100σ less. It was at first asserted that they were always less by this amount, but in most of the more recent experiments the difference has been smaller and has varied for individuals. Sound stimuli involve times of 110 – 125σ ; light, 170 – 180σ , and tactual, 105 – 110σ . The mean variation for the muscular reaction is smaller — from 6 – 9σ , as compared with 24 – 28σ for the sensory, and premature reactions are more frequent. The time required for any movement may be analyzed into four parts: the time required to stimulate the sense organ, the time of transmission along the nerve fibre, the time involved in passing from one nerve element to another and the time needed to excite the contraction in the muscle. The more important variables are the time required in the sense organ and the time for passing from one neurone to another. The greater length of the visual reaction is due to the longer time required to excite the retina, a photochemical process. The fact that reactions are shortened by training and by the attitude or preparation is a result of reducing the time needed to pass from one nerve element to another. The very short time of the reflex winking on stimulation of cornea (as little as 35σ) is probably explained by its having a path in the subcortical tracts with relatively few elements to pass over. The simplest of the compound reactions is the discrimination reaction. In this the reactor is asked to discriminate between two or more stimuli before he responds. The time required increases with the number of objects or quali-

ties between which discrimination must be made. Distinguishing between two qualities adds 20 – 30 to the sensory time, and when one must distinguish between 10, the time may be increased by 500σ or more. In the choice reaction, the reactor must make a different movement for each of the qualities. He may, e.g., react with the right hand to red and with the left to white, or he may be shown one of 10 colors and react with a different finger or thumb to each. The times for the choice reaction vary greatly with the individual and the amount of practice as well as with the complexity of the response demanded. They add to the discrimination time from 60 – 80σ when one of two movements may be chosen to 400σ or more when 10 movements are possible. In addition to these motor processes and processes essential to movement, measurements have been made of association times and the times involved in other more complicated mental processes. Association times are usually investigated by showing the observer a word and asking him to give some other word as quickly as possible. To think this word takes from 400σ to two seconds or more longer than it does to read a word. This time varies greatly with the individual and also with the conditions prescribed for the association. When one is left free to give any word whatever, one uses more time than when one is restricted in some way. Thus, when two numbers over each other are shown and one has been told in advance that one may either add, subtract or multiply, the response is more delayed than when one is told to add. In general, the smaller the number of possible associates the shorter the time. To name a member of the class when a class is given takes longer than to name the class when one member is shown. It might be noted that the association time is increased when the word arouses an emotion. This fact has been used by Jung as an aid in the detection of emotional complexes that may be responsible for hysteria. In explaining all responses and attempting to allot portions of the time to different acts, we must recognize that preparation of the act begins with the instructions. We may divide the process into two parts, the fore period from the time of receiving the instructions until the stimulus is given and the time between the stimulus and responses. During the fore period there is apparently a process of partially arousing the possible paths of discharge, and all that is necessary after the stimulus presents itself is to select the appropriate response from those that are already prepared. This "determining tendency" acts with the stimulus in deciding both the form of association and the nature of the response. This fact, that instruction and stimulus unite in determining the act, makes it impossible to divide the compound reaction into a number of part processes each distinct from the other. One does not see first, then discriminate, then choose and finally react, but the various processes overlap. Much of the choice is made before the stimulus is shown and the way for the association begins to be prepared when the instructions are heard. Studies of these conditions are valuable, for the explanation of action in general as well as for understanding the nature of reaction times. Consul Titchener, 'Text-book of Psychology' (pp. 428–447); Ladd-Woodworth, 'Elements of Physi-

ological Psychology' (pp. 476-499); Myers, 'Text-book of Experimental Psychology' (ch. XI); Ach, 'Die Willenstätigkeit und das Denken'; Alliotto, 'La misura in psicologia sperimentali.'

WALTER B. PILLSBURY,
Professor of Psychology, Univ. of Michigan.

READ, red, George, American patriot and jurist, one of the signers of the Declaration of Independence: b. Cecil County, Md., 18 Sept. 1733; d. New Castle, Del., 21 Sept. 1798. He was educated at Chester, Pa., studied law and was admitted to the bar in Philadelphia, soon afterward settling in New Castle, Del., where he practised his profession. He served as attorney-general for the Crown for the counties of Delaware, Kent and Sussex from 1763 to 1764, when he was elected a member of the first Continental Congress. Early an opponent of independence, at last he saw no alternative, and signed the petition to George III, the Declaration itself and later the Federal Constitution, the three fundamental documents of the American government. He was chairman (1775-77) of the first naval committee of the colonies, and is to be considered as one of the chief founders of the primitive American navy. The new constitution of Delaware (1776) was drafted by him and he was president of the convention which adopted it. He was made vice-president and acting president (governor) of the State of Delaware, whose laws he codified. In 1782 he was appointed judge of the United States Court of Appeals for Admiralty Cases. He was a delegate to the Annapolis Convention (1786) and to the Constitutional Convention (1787), and was elected to the United States Senate in 1789 and in 1791. Resigning in 1793, he became chief justice of Delaware and held that office during the rest of his life. Consult his 'Life and Correspondence' (1870).

READ, John Elliot, American journalist: b. South Amherst, Mass., 4 Jan. 1845. He was educated in the public schools and wrote much for agricultural, religious and literary periodicals. He was associate editor of *The Working Farmer* in New York 10 years, and corresponding editor of *The Practical Farmer*, Philadelphia, for 12 years, and on the editorial staff of 'Men of Mark in America' in 1903-09. He published 'Farming for Profit' (1880); 'Life Triumphant: A study of the Nature, Origin and Destiny of Man' (1900); also wrote 'A Brief History of the Principal Earlier Arctic Explorations from the 9th Century to the Peary Expedition' as the concluding section of 'Nansen in the Frozen World' (1897). In 1910 he became connected with the *Gazette*, Schenectady, N. Y., and the *Knickerbocker-Press*, Albany, N. Y.

READ, John Joseph, American naval officer: b. Mount Holly, N. J., 17 June 1842; d. 24 Oct. 1910. He was graduated from the United States Naval Academy, 1861, served under Farragut during the Civil War, and on the Atlantic blockades, and in 1866 was promoted lieutenant-commander. He received steady advancement, was made rear-admiral in 1900 with command of the receiving-ship *Richmond*, in 1901 was placed in command of the navy yard at Portsmouth, N. H., and in 1904 was retired.

READ, John Meredith, American jurist: b. Philadelphia, Pa., 21 July 1797; d. there, 29

Nov. 1874. He was a son of George Read, signer of the Declaration of Independence, was graduated at the University of Pennsylvania in 1812 and admitted to the bar in 1818. In 1822-23 he occupied a seat in his State's legislature, and later as city solicitor drew up the first statement of the finances of Philadelphia. He was United States attorney for the eastern district of Pennsylvania in 1837-44, and served as solicitor-general of the United States; attorney-general of Pennsylvania and chief justice of that State from 1860 until his death. In 1845 he was nominated for associate justice of the United States Supreme Court, but his confirmation was opposed in the United States Senate because he had been a founder of the free-soil wing of the Democratic party, and he withdrew his name. With the formation of the Republican party he became one of its members, and by it was elected judge of the Supreme Court of Pennsylvania in 1858. His name was proposed as a candidate for the presidency of the United States in 1860 and several votes were actually cast for him in the Chicago convention, though he used his personal influence in favor of Abraham Lincoln. His 'Views on the Suspension of the Habeas Corpus' (1863) became the basis of the act of 3 March 1863, authorizing the President to suspend the habeas corpus act. His legal opinions extend through 41 volumes of reports, while of his published addresses the principal are 'Plan for the Administration of the Girard Trust' (1833); 'The Law of Evidence' (1864); 'Jefferson Davis and his Complicity in the Assassination of Abraham Lincoln' (1866).

READ, John Meredith, American diplomatist: b. Philadelphia, Pa., 21 Feb. 1837; d. Paris, 27 Dec. 1896. He was a son of Judge Meredith Read (q.v.), was graduated at Brown University in 1858, and at the Albany Law School in 1859. He pursued the study of international law in Europe, was admitted to the bar in Philadelphia and settled at Albany. From 1860 to 1866 he was adjutant-general of the State of New York. In 1869 he was appointed United States consul-general at Paris, and during the period of the Franco-Prussian War he acted there also as consul-general for the German government, for which he received the thanks of both the French and German governments, and personal recognition of his services from Prince Bismarck. From 1873 to 1879 he was United States Minister to Greece, and during the latter part of his tenure of office personally paid the expenses of the legation, when the government refused the appropriation, he believing that the time was too critical to close the mission. His important services during his term were his securing the revocation by the Greek government of an order prohibiting the sale of the Bible in Greece; the release of the American ship *Armenia*, and the report of an open Russian port during the Turkish War, to which he urged the despatch of a grain fleet. After his relinquishment of diplomatic duties he continued to reside in Europe, engaged in archæological, historical and art studies. He was the author of a 'Historical Inquiry Concerning Henry Hudson' (1866).

READ, Nathan, American inventor: b. Warren, Worcester County, Mass., 2 July 1759; d. near Belfast, Maine, 20 Jan. 1849. He was graduated from Harvard in 1781; studied medicine; in 1796 established with others the Salem iron foundry, where chain cables and other iron work for ships were manufactured, and in 1798 patented a nail-making machine. In 1788 he became interested in steam navigation, and as his first task attempted the construction of a boiler that should be at once compact, light and safe. He made, in 1788 or 1789, the first drawings of what he styled his "portable furnace boiler," which was devised for use on steam carriages and steamboats, and for which he obtained a patent 26 Aug. 1791. He had built a steamboat in 1789, and by a trial of this craft, which was fitted with paddle-wheels and a crank operated by hand, was satisfied that his method of applying steam to the propulsion of vessels would work suitably. This steamboat is said to have been substantially identical with that of Fulton's of 1807, and it is further stated that he withdrew his application for a patent in 1790, under a misapprehension. There is no evidence, however, that he succeeded in even an experimental demonstration of his plans. His model steam carriage, exhibited by him while endeavoring to obtain aid in his schemes, was never developed. He did, however, invent the vertical multi-tubular firebox boiler, which has long been in use as a standard form. Among his other inventions were several forms of pumping engines, and a plan for utilizing the force of the tide by means of reservoirs alternately so filled and emptied as to produce a continuous stream of water. Much credit belongs to Read for his early and clear perception of the importance of steam navigation. From 1800 to 1803 he was a Federalist representative in Congress, and after his removal to Maine was for many years chief justice of the Court of Common Pleas of Hancock County. Consult Read, 'Nation Read' (1870); Thurston, 'A History of the Growth of the Steam Engine' (1878).

READ, Opie Percival, American journalist and novelist: b. Nashville, Tenn., 22 Dec. 1852. He was educated in Gallatin, Tenn.; entered journalism at Franklin, Ky., and later removed to Little Rock, Ark. He edited the *Arkansas Gazette* in 1878-81; founded the *Arkansas Traveler* in 1883, and edited it for eight years, and then removed to Chicago, where he devoted himself to literary work. His publications include 'Len Gansett' (1888); 'Up Terrapin River' (1889); 'A Kentucky Colonel' (1890); 'My Young Master' (1896); 'In the Alamo' (1900); 'Our Josephine' (1902); 'An American in New York' (1905); 'The Mystery of Margaret' (1907), etc.

READ, Thomas Buchanan, American poet and painter: b. Chester County, Pa., 12 March 1822; d. New York, 11 May 1872. His father was a farmer and he received but little schooling. He lived at various times during his youth and young manhood at Philadelphia, Cincinnati, New York and Boston, occupied in ways that satisfied his tastes, such as portrait painting and writing verses, when he could; and in other ways that supplied his necessities, such as sign painting, cigar making, play acting, when he must. He published his first verses in the

Boston Courier in 1843-44; later a Revolutionary tale 'Paul Redding' (1845) and 'Poems' (1846), before his removal to Philadelphia, where he edited 'The Female Poets of America' (1848), and brought out his 'Lays and Ballads' (1849). In 1850 he went to Europe and joined the circle of American artists living at Rome. Here he had the first opportunity for the serious study of painting, and for the rest of his life, save for occasional visits to America, he made his home at Rome. His better known paintings are 'The Water Sprite'; 'The Lost Pleiad'; 'The Star of Bethlehem'; 'Sheridan and his Horse.' He made portraits of Mrs. Browning, the ex-Queen of Naples, Henry W. Longfellow and a group of Longfellow's children. His portrait of George Peabody is at the Institute in Baltimore. A sculptured bust of General Sheridan was executed late in life. It is as a poet, however, that he will be remembered, especially by his stirring 'Sheridan's Ride,' written for the elocutionist and actor, James E. Murdock, and the exquisitely musical lyric 'Drifting.' His volumes of verse are 'The New Pastoral' (1855); 'Sylvia or the Last Shepherd' (1857); 'The Wagoner of the Alleghanies,' in which occurs the fine lyric 'The Maid Who Binds Her Warrior's Sash' (1862). A complete edition of his poems was published in 1882.

READE, red, Charles, English novelist and play-writer: b. Ipsden House, Oxfordshire, 8 June 1814; d. Shepherd's Bush, London, 11 April 1884. He was graduated at Oxford in 1835, at which he obtained a fellowship, and was called to the bar in 1843, but, finding literature more attractive than law, devoted himself to the former and never practised. He became first known by a comedy (in conjunction with Tom Taylor) called 'Masks and Faces,' which he presently elaborated as the novel of 'Peg Woffington' (1852). This was followed by 'Christie Johnstone' (1853), in which he showed considerable appreciation of certain characteristics of Scottish life. The appearance, in 1856, of 'Never Too Late to Mend,' one of his "novels with a purpose," in which he attacked the English prison system with perhaps greater zeal than unbiased judgment, secured for him a wide reputation. His next great work, the most scholarly and artistic of his writings, 'The Cloister and the Hearth,' dealing with the lives of the parents of Erasmus, appeared in 1861, is decidedly his masterpiece, and has been described by Besant as the greatest historical novel in the language; but it has not attained the popularity, with the general reader, of some of his more melodramatic novels. Among the more important of his other works are 'Love Me Little, Love Me Long' (1859); 'Hard Cash' (1863); 'Griffith Gaunt' (1866); 'Foul Play' (with Dion Boucicault, 1869); 'Put Yourself in His Place' (1870); 'A Terrible Temptation' (1871); 'The Wandering Heir' (1872); 'A Perilous Secret' (1884). He was also the author, either alone or in collaboration with others, of several dramas, including 'Gold'; 'Two Loves and a Life'; 'The King's Rivals'; and 'Drink,' the last adapted from Zola's 'L'Assommoir.' None of these won much success for Reade. His 'Courier of Lyons,' renamed 'The Lyons Mail,' has been made famous by Sir Henry

Irving in the dual rôle of Lesurques and Dubosc. Reade was enthusiastic by nature, and continually filled with new enthusiasms toward any cause which roused his easily excited interest. The abuses in the convict prison system produced, as was said, one of his best-known novels; the system of private lunatic asylums furnished the motive for 'Hard Cash,' as the trades-union outrages at Sheffield did for 'Put Yourself in His Place,' while in 'Foul Play' he attacked the alleged practice of overloading and over-insuring ships. His writings show considerable skill in the delineation of character, much narrative, descriptive and dramatic power, combined at times with coarseness and theatricality, and they were based on much painstaking research. He may, perhaps, be said to rank first in the second order of English novelists of the 19th century, and was as popular in this country as in his own. See CLOISTER AND THE HEARTH, THE. Consult Swinburne's article in his 'Miscellanies' (1886); 'Charles Reade: A Memoir' (1887); Ireland, 'Extracts,' with an introduction (1891); and the *Gentleman's Magazine* for 1882.

READE, John, Canadian journalist: b. Ballyshannon, Ireland, 13 Nov. 1837. He was educated at Queen's College, Belfast, and in 1856 went to Canada, where he founded the *Montreal Literary Magazine*, engaged in teaching, practised law at intervals, and in 1864 took orders in the Church of England, afterward beginning his association as editorial writer with the *Montreal Gazette* which he has ever since maintained. In 1887 he was elected president of the Montreal Society for Historical Studies. He wrote 'The Prophecy and Other Poems' (1870); 'Language and Conquest' (1883); 'The Making of Canada' (1885); 'Vita sine Liberis' (1886); 'Aboriginal American Poetry' (1887), etc.

READE, William Winwood, English traveler and novelist, nephew of Charles Reade (q.v.): b. Ipsden, Oxfordshire, 30 Jan. 1838; d. Wimbledon, Surrey, 24 April 1875. He visited the western coast of Africa in 1862, and in 1868 started from Sierra Leone and reached close to the source of the Niger. He was special correspondent for the *London Times* in the Ashantee War, 1873-74. Of his literary work perhaps his most notable effort is 'The Martyrdom of Man' (1872), a history of human slavery. His other works include 'The Veil of Isis' (1861); 'Savage Africa' (1863); 'The African Sketch Book' (1873); 'Story of the Ashantee Campaign' (1875); 'The Outcast' (1875), etc.

READER, Francis Smith, American journalist: b. Coal Centre, Pa., 17 Nov. 1842. He served with the Union army throughout the Civil War, and was connected with the United States Civil Service for 10 years. Later he became editor of the *Beaver Valley News*. He published 'Life of Moody and Sankey' (1890); 'History of the 5th West Virginia Cavalry' (1890); 'History of New Brighton, Pa.' (1899); 'Some Pioneers of Washington County, Pa.' (1902); 'History of the Newspapers of Beaver County, Pa.' (1905); 'History of Schools, New Brighton, Pa.' (1910), and a number of historical monographs.

READER. See HOLY ORDERS.

READING, rēd'ing, England, parliamentary and county borough and capital of the county of Berkshire, 28 miles southeast of Oxford. It has handsome municipal buildings; a public hall and free library; a museum, university college and excellent schools and a fine public park. There are remains of the magnificent Benedictine Abbey founded by Henry I, in which he was buried. Henry VIII converted the castle into a palace; later it was destroyed during the Cromwellian wars, and the gateway alone has been restored. Other churches are Saint Mary's, rebuilt from a nunnery founded by Elfrida to expiate the murder of her stepson (Edward the Martyr); Saint Lawrence (Norman), rebuilt in the 15th century; Saint Giles' (mixed architecture), and Greyfriars Church. Reading was the headquarters of the Danes in 871; was a refuge for the students who defied the Parliament; for the law courts obliged to leave London to escape the terrible plague, and was the fighting ground of rival armies during the conflicts of the rebellion. Reading is the centre of a large agricultural district, and is celebrated for its biscuits and seeds. Archbishop Laud and Goldwin Smith were natives. The borough returns one member to Parliament. Pop. 89,419.

READING, Mass., town in Middlesex County, on the Boston and Maine Railroad, about 10 miles north of Boston. It was settled in 1638, and six years later was incorporated. It is a beautiful residential town, and has considerable manufacturing interests. The chief manufactured products are imitation leather, wire brushes, boots and shoes, rubber and rubber goods, games, church organs and organ pipes, toys and furniture. The public library contains nearly 10,000 volumes. The government is administered by town meetings, which convene annually. Pop. 5,818.

READING, Ohio, village in Hamilton County, on the northern outskirts of Cincinnati, and on the Pittsburgh, Cincinnati, Chicago and Saint Louis Railroad. It is the seat of Mount Notre Dame Academy. Manufactories include fireworks, cigars and bottles, and there is also an industry in mineral waters. Pop. 3,985.

READING, Pa., city, county-seat of Berks County, on the Schuylkill River and the Schuylkill Canal, and on the Pennsylvania and the Philadelphia and Reading railroads, about 58 miles northwest of Philadelphia, and 54 miles east of Harrisburg. Its area is about 10 square miles. Reading was first settled by English colonists, sons of William Penn, and was named after Reading in England. In 1748 it was laid out, and in 1783 was incorporated as a borough. It was chartered as a city in 1847. It is in an agricultural region. It has extensive manufacturing and commercial interests. Immediately east of the city is Mount Penn, and south of it is Neversink Mountain. Electric railways encircle both mountains. Mount Penn is 1,140 feet above sea-level. The chief industries are connected with iron and steel productions. The chief industrial establishments are railroad shops, machine shops, foundries, optical goods, builders' hardware, paper mills, breweries, knitting mills, hosiery mills, hat factories, carriage works, cigar factories and iron and steel works. The capital

invested in manufacturing in 1909 (Federal census) was \$45,334,000 and the average annual output was valued at \$53,232,000. The iron and steel industries had the largest invested capital and about one-fourth of the output. There were, in 1910, over 500 manufacturing establishments, representing about 100 different industries. The principal public buildings of Reading are public library, Y. M. C. A., Boys' High School and the churches. The charitable institutions are Saint Catherine's Orphan Asylum (girls), Saint Paul's orphanage (boys), the Home for Friendless Children, House of the Good Shepherd, Saint Joseph's, the Reading, and the Homœopathic hospitals. The educational institutions are the Schuylkill Seminary, two high schools and a business school.

The city has an excellent park system covering in all nearly 200 acres. The city is governed by a commission, a mayor and four councilmen. The members of the board of education are chosen by popular election. During 1915-16 there was an enrolment of more than 15,000 children, the total expenses for the year being \$550,000. The annual municipal expenditures for maintenance and operation are about \$1,052,000; the chief items being, for streets and public improvements, \$190,000; park and public property, \$150,000; public safety, \$140,000; public affairs, \$125,000; accounts and finance, \$25,000. The waterworks cost the city originally \$1,937,762. They are owned and operated by the municipality. In 1867, 1869, 1914 and 1915 the city boundaries were enlarged. Pop. (1783), when it became a borough, 2,100; (1847), when chartered, 12,000; (1900) 78,961; (1910) 96,071; (1916) 110,000.

READING OF EARLEY, Rufus Daniel Isaacs, 1st earl, British jurist: b. London, 10 Oct. 1860. The son of a fruit merchant, he was educated at University College School, London, and in Brussels and Hanover. For a time he was a seaman on a coal ship running to South America, and acted as his father's agent in Magdeburg. He took up the study of law, was called to the bar and in 1898 became queen's counsel. In 1904 he was elected to the House of Commons as a Liberal member for Reading. In 1910 he was knighted and made successively solicitor-general and attorney-general. His part in the libel suit against Edward Mylius, who had published an old fiction to the effect that King George V had contracted an early secret marriage, won Isaacs increased royal favor, for he had already been a personal friend of the previous king. As a lawyer, Sir Rufus held a high reputation as a fair attorney, with a remarkable mastery of financial and technical details acquired as a member of the Stock Exchange. His brilliant powers of cross-examination and forensic erudition marked him for the highest honor. He was invited to a seat in the Cabinet in 1912, the first time that an attorney-general received that distinction. Together with the then Chancellor Lloyd George, he was accused of speculation in Marconi stock, admitted the charge and seemed to lose nothing in political prestige with his own party. He was one of the staunchest defenders of the Liberal financial policy in the Home Rule Bill of 1913. Late in that year the lord chief justice, Lord Alverstone, retired on account of ill-health and Sir Rufus Isaacs succeeded him.

He was the first Jew to hold that important position. In 1914 he was elevated to the peerage, and in 1915 headed the Anglo-French commission to the United States to arrange for the American loan of \$500,000,000. On 7 Jan. 1918, the Earl of Reading was appointed British High Commissioner in the United States "in the character of Ambassador Extraordinary and Plenipotentiary on Special Mission," with full authority over the members of all British missions sent to the United States in connection with the active prosecution of the war. Consult Gardiner, A. G., 'Prophets, Priests and Kings' (London 1908).

READJUSTERS, or REFUNDERS, the name of a political party in Virginia, which passed several bills providing for the scaling and partial rejection of the public debt of the State. Virginia, at the close of the Civil War, was greatly impoverished, burdened with a large indebtedness, and shorn of part of its territory, which had been erected into the State of West Virginia. The reconstruction government added considerably to the debt, and a keen controversy arose over the question of meeting the obligations. An act passed in the legislative session of 1870-71 to refund the debt was repealed, but the repeal was declared unconstitutional by the courts. In 1878 the legislature passed a measure known as the McCulloch bill, which provided for new bonds, to be exchanged at par for outstanding bonds, and to bear interest at 3 per cent for 10 years, 4 per cent for the following 20 years, and 5 per cent for 10 years, when the principal would fall due. This act did not satisfy those opposed to payment of the debt in full, who became known as "Readjusters," and included in their ranks both Democrats and Republicans. Under the leadership of H. H. Riddleberger they succeeded in getting control of the legislature, and passed a bill scaling the debt from \$31,102,571 to \$19,665,196. This bill was vetoed by the governor. In 1881 the Readjusters obtained complete control of the State, and laws were enacted in accordance with their policy, the same course being pursued in 1884, 1886 and 1887. The United States Supreme Court delivered nine opinions declaring the readjustment measures, so far as they prohibited the receipt of State bond coupons for taxes, as provided by the McCulloch law, to be in conflict with the provision of the Federal Constitution, upholding the obligation of contracts. The State could not be coerced into payment, and matters remained unsettled until a compromise was agreed upon between the State and holders of the bonds.

REAGAN, ré'gan, John Henninger, American politician: b. Sevier County, Tenn., 8 Oct. 1818; d. Palestine, Tex., 6 March 1905. He acquired a limited collegiate education, studied law and was admitted to the bar and in May 1839 settled in the republic of Texas to practice. He was a deputy surveyor of public lands in 1839-43, was elected to the State house of representatives in 1847, served as judge of the District Court in 1852-57 and was a Democratic representative in Congress in 1857-61. In the latter year he was a member of the Secession Convention of Texas, a deputy to the Provisional Confederate Congress, and became postmaster-general of the Confederate States, and acting secretary of the Confederate treasury.

He was a member of the Texas Constitutional Convention 1875, member of the Congress 1875-97, United States Senator 1887-91, and chairman of the Texas State Railroad Commission in 1897-1903. He introduced the "Reagan Inter-State Commerce Bill," on which the subsequent interstate commerce legislation has been based.

REAL, *re'al*, a Spanish coin, the old unit of value in Spain. By the monetary law of June 1864, the silver real was made to weigh 1.298 grams, .81 fine and equivalent to $4\frac{1}{2}$ cents. It has varied in value from $4\frac{1}{2}$ to 10 cents.

REAL NUMBERS. See ALGEBRA.

REAL PRESENCE, the doctrine of the actual presence of the body and blood of Christ in the Eucharist. See CONSUBSTANTIATION; EUCHARIST; MASS; TRANSUBSTANTIATION.

REAL PROPERTY. See PROPERTY, LAWS OF.

REAL VARIABLE, Theory of Functions of the; a mathematical science. A variable is a symbol (such as x or y or "time" or "temperature") which stands for any member of a class of things. A particular member of the class is called a "value" of the variable which is said to "take on" its values. One variable, y , is said to be a single-valued function of another variable, x , if to every value of x there corresponds one and only one value of y . This is the case, for example, if x stands for any number and $y = x^2$. It is customary to express such a relation between y and x by the equation $y = f(x)$; x is called the independent and y the dependent variable. If the restriction that only one value of y shall correspond to each value of x is removed, y is called a multiple-valued function of x . Unless otherwise provided, the word function in the following pages shall mean single-valued function.

While the notions of variable and function as thus defined apply to any class of objects whatever, they are usually thought of only in connection with classes of numbers. In fact the phrase Theory of Functions is at present understood by mathematicians to mean either the theory of functions of a complex variable (q.v.) or the theory of functions of a real variable. In a certain abstract sense, the theory of the complex variable might be supposed to include the theory of the real variable, since all values of the real variable x_1 are included as special values ($x_2 = 0$) of the complex variable $x_1 + x_2\sqrt{-1}$. As matter of fact, however, the theory of functions of a complex variable has yet concerned itself but little except with analytic functions, i.e., those functions which may be thought of as defined by a power-series together with its continuations. This theory, therefore, leaves untouched the widest class of functions of the real variable. On the other hand, since the theory of functions of a complex variable gives a broader and hence more unified theory of analytic functions than can be furnished by the real function theory, these functions are not ordinarily given special attention in the latter theory. For a discussion of algebraic functions the reader is referred to the article on Algebra; for transcendental functions, i.e., functions which are not algebraic, see TRIGONOMETRY; HARMONIC ANALYSIS; EQUATIONS; SERIES, etc.

The theory of functions of a real variable is a product of the critical tendency of mathematics in the latter half of the 19th century. It has yielded comparatively few new theorems about the functions hitherto studied in applied mathematics, and has therefore had less influence on these sciences than has the complex variable theory. Its main business has been the restatement in rigorous form and with proper limitation of generality, the brilliant though sometimes inexact theorems won by the earlier students of infinitesimal calculus. For example, the study of vibrating strings, membranes, etc., and of the conduction of heat led to the celebrated trigonometric series of J. B. J. Fourier (q.v.), which was at first incorrectly supposed to furnish a method of representing an arbitrary function. The reconsideration of this series and the attempt to determine exactly what functions are expandible by trigonometric series has led to many of the most abstruse theorems about point-sets. The theory of point-sets (Punktmengen, 'Assemblages of Points'; see article ASSEMBLAGES, GENERAL THEORY OF), it should be remarked in explanation of the proportionately large space allotted to it below, is the most characteristic feature of real function theory.

The Real Variable.—The real numbers are, first, the whole numbers positive and negative; second, the rational fractions of the form m/n where m and n are whole numbers, and, third, the irrational numbers such as $\sqrt{2}$ and π . On this subject, see the articles on ARITHMETIC and ALGEBRA and the BIBLIOGRAPHY at the end of this sketch. (Reference numbers such as that on the word Bibliography correspond to the numbers attached to works in the Bibliography).

The totality of real numbers is a field (Körper), i.e., a set of elements upon which can be performed the operations of addition and multiplication, according to the well-known rules.¹ We suppose also known the derived operations of subtraction, division and raising to a power. A special symbol is used to distinguish the numerical from the algebraic value of a number: if x is positive, $|x| = x$, if x is negative, $-|x| = x$. The relation of greater and less is indicated by the symbols $<$, $>$; $a > b$ means a is greater than b , $a < b$ means a is less than b . Considerable attention has been given to the problem of stating explicitly the hypotheses of the real number system. We state here only that one the discussion of which has had the most far-reaching consequences.

Principle of Continuity.—If $[x]$ is any set of real numbers all less than a certain number, b , then there is a number, $\bar{x}$, such that every number of $[x]$ is less than or equal to $\bar{x}$, and such that $\bar{x}$ is the smallest number of which this is true. In other words, $x \leq \bar{x}$ for every x of $[x]$, and if $a < \bar{x}$, there is a number x' of $[x]$ such that $a < x'$.

Any number, such as b in the statement above, which is larger than every number of a set $[x]$ is called an upper bound of $[x]$; a number smaller than every number of a set $[x]$ is called a lower bound of $[x]$. In this language the principle of continuity says that every set having any upper bound has a least upper

bound. It follows immediately that every set having a lower bound has a greatest lower bound. The greatest lower bound or least upper bound of a set may or may not belong to the set. Thus, zero is the greatest lower bound of the set of all positive numbers but does not belong to it; on the other hand, zero is the least upper bound and does belong to the set of all real numbers which are not positive.

A very large proportion of the advances in critical sharpness of the modern analysts over those of the 17th and 18th centuries is due to the recognition of places where the earlier analysts had unconsciously assumed, or had neglected to apply, the principle of continuity. The form in which this postulate is here stated is due to K. Weierstrass^{1, 2}. Other forms have been given by R. Dedekind³ and G. Cantor⁴. Indeed, the theory of continuity and irrational numbers is due about equally to these three great Germans.

Segment, Interval, Limit Point.—By the method of analytic geometry (q.v.) there is a correspondence between the totality of real numbers and the points of a line; likewise between the set of all pairs of numbers (x, y) and the points of a plane, the pair (x, y) corresponding to the point of which x and y are the co-ordinates. On account of this correspondence, it is customary to use geometrical language in the theory of real functions; thus, the word point is used interchangeably with the word number. A linear segment is the set of all numbers x , $a < x < b$, or the set of all points between a and b ; a planar segment is the interior of a parallelogram with sides parallel to the co-ordinate axes, or the set of all number-pairs (x, y) , $a < x < b, c < y < d$. The word interval is used for a segment plus its boundaries, i.e., $<$ is replaced by $\leq$ in the

definition just given. A segment linear or planar as the case may be, including a point, is called a neighborhood of the point.

Among the most important consequences of the principle of continuity is the following theorem which was first stated in a slightly different form by E. Borel¹¹ in 1895. Since its method is essentially involved in the proof of the theorem of uniform continuity (see below) given by E. Heine⁶ in 1871, it is usually called (after A. Schoenflies⁹) the Heine-Borel theorem: "Every set of segments $[\sigma]$ such that every point of an interval, i , is an interior point of at least one σ , has a finite subset $\sigma_1, \sigma_2, \dots, \sigma_n$, such that every point of i is an interior point of at least one σ_k ($k=1, 2, \dots, n$)."

We shall prove this theorem only for the linear case, the proof of the planar case being quite analogous. Let the end points of the interval i be a and b , $a < b$. Let $[b']$ be a set including every point, b' , of i such that the interval ab' is contained in a finite number of segments of $[\sigma]$. There is at least one b' ; for one of the end points of any segment of $[\sigma]$ which includes a is evidently a point of $[b']$. By the principle of continuity, the set of all

points, $[b']$, has a least upper bound B , $B \leq b$. We shall prove that B is a point of $[b']$ and that $B=b$.

Let $a''b''$, $a'' < b''$, be a segment of $[\sigma]$ including B . Since B is the least upper bound of $[b']$

there is a point of $[b']$, b'_1 between a'' and B . But if $\sigma_1, \sigma_2, \dots, \sigma_n$ is the finite set of segments including all points of the interval ab'_1 , this set together with $a''b''$ will include B , which proves that B is a point of $[b']$. Moreover, if $B < b$, the set $\sigma_1, \sigma_2, \dots, \sigma_n$ together with $a''b''$ would include every point of an interval ac , c being a point between B and b'' . c would therefore be a point of $[b']$ contrary to the hypothesis that B is an upper bound of $[b']$. Hence $B=b$ and the Heine-Borel theorem is proved.

A point a in every neighborhood of which there are points, distinct from a , of a set $[x]$ is a limit point of $[x]$; a either may or may not be a point of the set $[x]$. If $[x]$ is a linear set, a is either the greatest lower bound of the numbers of $[x]$ greater than it or the least upper bound of the numbers of $[x]$ smaller than it. A linear point-set without an upper bound is said to have the limit point $+\infty$ and one without a lower bound to have the limit point $-\infty$. The following theorem of Weierstrass is a simple corollary of the Heine-Borel theorem.

"Every infinite set of points lying on an interval has at least one limit point." If it had no limit point, then about every point of i there would be a segment including not more than one point of $[x]$. This set of segments, by the Heine-Borel theorem, would have a finite subset including all the points of i . But each interval of the subset not containing more than one point of $[x]$, $[x]$ could contain at most a finite number of points, contrary to hypothesis.

If $[x]$ is a linear point-set, and if we allow $+\infty - \text{pue } \infty$ to figure as limit points, the theorem may, of course, be modified to read: Every infinite linear point-set has at least one limit point.

Theory of Linear Point-sets.—The set of limit points of a set $[x]$ is called the first derived set of $[x]$. The first derived set of the first derived set is the second derived set, etc. The theory of successive derived sets has been highly developed by the aid of the transfinite numbers of Cantor.¹ (See ASSEMBLAGES). A set which includes its first derived set is said to be closed (*abgeschlossen*). A set included in its derived set is dense in itself (*insichdicht*). A set which is the same as its first derived set, i.e., which is both closed and dense in itself, is said to be perfect. An example of a set closed but not dense in itself is furnished by the number 0, together with the numbers $\frac{1}{2^n}$ ($n=1, 2, 3, \dots$). A set dense in itself but not closed is the set of all rational numbers. The set of all numbers is an example of a perfect set.

A set whose derived set is the set of all real numbers on a certain interval is everywhere dense (*überalldicht*) on this interval. Such a set has a point between every two points of the interval. A set which is everywhere dense on no interval is nowhere dense. The first of the examples above is a nowhere-dense set, the second and third are everywhere-dense sets.

If $[x]$ is a closed set, nowhere dense on an interval ab , and c any point of ab not in $[x]$ then there is a segment, including c , whose end points belong to $[x]$, but which contains no point of $[x]$. Such a segment is called a point-free segment of $[x]$. Thus, for every closed set $[x]$ there exists one, and only one, set of point-free segments. No two of these segments overlap.

Therefore they are an enumerable (or denumerable) set (see ASSEMBLAGES), namely, there can be only a finite number of length $\geq \frac{b-a}{2}$, a

finite number of length $\geq \frac{b-a}{4}$, and in general

only a finite number of length $\geq \frac{b-a}{2^n}$. The set

$[s]$ of end points and limit points of end points of the point-free segments is evidently a closed set and is identical with $[x]$. Since the set of point-free segments is enumerable, its end points are enumerable and thus the nowhere-dense closed set is the derived set of an enumerable set of points together with the enumerable set itself. A consequence of this which we do not stop to prove here is that there is a one-to-one correspondence between the continuum and any perfect subset of itself; the argument depends on the theory of point-free segments and the fact that the continuum is the derived set of the enumerable set of all rational numbers.⁸

The notion, length of an interval, finds a generalization in the content of a point-set. $[x]$ being any set of points on an interval i , let $\sigma_1, \sigma_2, \dots, \sigma_n$ be any finite set of intervals of length $l_1, l_2, \dots, l_n$, including every point of $[x]$. Let $L = l_1 + l_2 + \dots + l_n$. There are, of course, an infinity of numbers, L . Their greatest lower bound is called the content of $[x]$ and written $c[x]$. If $[x]$ is a closed set and S is the sum of the finite or infinite series obtained by taking the lengths of the point-free segments in the order of their magnitude, we have $c[x] = l - S$, where l is the length of the interval i . Thus in the case of a closed set $[x]$ and its complementary set $[x]$, which consists of all points of the interval not points of $[x]$, we have $c[x] + c[\bar{x}] = l$. This, however, is not true of sets in general. For example, the set of all rational numbers between 0 and 1 has the content unity and the set of all irrational numbers on the same interval has the same content. The notion of length is, therefore, extended by the definition of content, only to closed sets and not to sets in general. A much more far-reaching generalization of length has, however, been suggested by E. Borel¹² and carried out by H. Lebesgue¹³ in connection with the theory of definite integrals (see below). (See also *Measure and Measurable Assemblages*, under ASSEMBLAGES, GENERAL THEORY OF).

Functions Defined on an Interval.—On account of the generality of the definition, practically no theorems are known which apply to all functions on a given interval. One of the most general theorems known is obtained by introducing the restriction that on a certain interval, $f(x)$ shall have an upper bound. By this it is meant that there shall be a number, B , such that for every x on the given interval $f(x) < B$. From the principle of continuity it

is clear that a function having an upper bound upon an interval, i , has a least upper bound B_i , and by aid of the Heine-Borel theorem, it is easily proved that there is at least one point, x_1 , on the interval, such that for every interval of i which includes x_1 , B_i is the least upper bound of $f(x)$. This is a theorem of Weierstrass.¹

Another broad class of functions is that of

the monotonic functions.¹ A function, $f(x)$, is monotonic increasing if whenever $x_1 < x_2$, $f(x_1) < f(x_2)$; it is monotonic decreasing if whenever $x_1 < x_2$, $f(x_1) > f(x_2)$. In the case of a monotonic function, $f(x)$, not only is there a single value of $y = f(x)$ for every value of x , but for every value of y taken on by $f(x)$ there is one and only one value of x . In this case it is the custom to write $x = f^{-1}(y)$ and to call $f^{-1}(y)$ the inverse function of $f(x)$. Thus every monotonic function, $f(x)$, has a single valued inverse which, however, is not necessarily defined for all values of y .

In antithesis to the monotonic functions stand oscillating functions, those such that on the interval under consideration there are three values of the independent variable, x_1, x_2, x_3 , $x_1 < x_2, x_2 < x_3$ such that $f(x_1) < f(x_2)$, $f(x_2) > f(x_3)$, or $f(x_1) > f(x_2)$, $f(x_2) < f(x_3)$. There exist functions which oscillate on every interval; indeed, a function may oscillate on every interval and still be continuous and have a continuous derivative.⁸ The definition of continuity is given below and of derivation in the article CALCULUS. In most investigations hitherto the functions considered have had only a finite number of oscillations, i.e., there would exist a finite set of points such that on the intervals between successive points the function would not oscillate. It is to be noted that a non-oscillating function is not necessarily monotonic; there may be intervals upon which it is a constant.

The word oscillation is also used to denote a measure of the total amount of variation of a function on a given interval, that is, the difference between the upper and lower bounds of $f(x)$. This is a satisfactory measure in case $f(x)$ is monotonic. In other cases, especially in case of functions with oscillation on every interval, this scheme is naturally extended as follows: Let $x_1, x_2, x_3, \dots, x_{n-1}$ be any finite set of points on the interval ab in the order $a < x_1 < x_2 < x_3 < \dots < x_{n-1} < b$. Calling $a = x_n$ and $b = x_0$, we have $\sum_{k=1}^n (f(x_k) - f(x_{k-1})) = f(b) - f(a)$.

But $\sum_{k=1}^n |f(x_k) - f(x_{k-1})| = R$ is, except for non-oscillating functions, different from $f(b) - f(a)$. For every infinite set of points $x_1, x_2, \dots, x_{n-1}$, there is a value of R . The least upper bound, V , of the set of all possible numbers, R , is called the variation of $f(x)$ on the interval ab . A function for which V is finite is called a function of limited variation; such a function can always be expressed as the difference between two monotonic functions. Functions of limited variation were first defined and studied by C. Jordan in connection with the theory of lengths of curves.

Theory of Limits.—Turning from the description of a function by its properties on an interval to a consideration of its appearance in the immediate neighborhood of a point, we are led to consider the notions of limits and of continuity. If a is a limit point of a set of points $[x]$, then the variable x is said to approach a on the set $[x]$. In case all the values of x are $> a$, the approach is said to be

from above, and in the opposite case, from below. Let $f(x)$ be a function which is defined

and bounded on an interval ab , $a < b$, and let $x_1, x_2, \dots$ be any set of points of ab of which a is the only limit point. Such a set is, for example,

$$a + \frac{b-a}{2}, a + \frac{b-a}{4}, \dots, a + \frac{b-a}{n}, \dots$$

The points whose co-ordinates are $(x_i, f(x_i))$, $(x_2, f(x_2))$, etc., in the graphical representation of $f(x)$ are a bounded set in the plane, and, therefore, have at least one limit point. The x co-ordinate of this point cannot be other than a , since every other x co-ordinate may be surrounded by a segment including at most one point of the set, $x_1, x_2, \dots$. Call the y co-ordinate of this point, y_0 . The value y_0 is such that for every pair of positive numbers, ϵ and δ , there is a value of $x > a$, such that $|x - a| < \delta$ and $|f(x) - y_0| < \epsilon$. A number, y_0 , satisfying this condition is called a value approached by $f(x)$ as x approaches a from above. If in every interval ax of ab , $f(x)$ is without an upper bound, $f(x)$ is said to approach the value of $+\infty$ as x approaches a from above; if $f(x)$ is without a lower bound in every interval ax , $f(x)$ approaches $-\infty$. Thus we have the highly important theorem that as x approaches any finite value from above (and by parity of reasoning, from below) $f(x)$ approaches at least one value, finite or infinite.

A finite value approached by $f(x)$ as x approaches $+\infty$ is a number, y_0 , such that for every pair of positive numbers, ϵ and δ , there is a value of x such that $x > \delta$ and $|f(x) - y_0| < \epsilon$, $f(x)$ approaches $+\infty$ as x approaches $+\infty$ if, for every ϵ and δ , there is a value of x such that $x > \delta$ and $f(x) > \epsilon$. The definition of approach to $-\infty$ is analogous. In the case where x approaches a finite value, x_0 , from above or below or from both sides, $f(x)$ approaches y_0 if for every pair of positive numbers, ϵ and δ , there is a value of x ($x \neq x_0$), such that $|x - x_0| < \delta$ and $|f(x) - f(x_0)| < \epsilon$. The theorem of the last paragraph now extends to all cases: if x approaches any value finite or infinite, $f(x)$ approaches at least one value, finite or infinite.

If $f(x)$ approaches only one value as x approaches a , the value approached is said to be the limit of $f(x)$ (or limiting value of $f(x)$) as x approaches a , and is indicated by the symbol $Lf(x)$ or simply $Lf(x)$. If $Lf(x) = f(a)$

the function $f(x)$ is said to be continuous at the point $x = a$. A necessary and sufficient condition for the existence of the equality $Lf(x) = b$ is the following: for every $\epsilon > 0$ there exists a $\delta_\epsilon > 0$, such that for every $x \neq a$ for which $|x - a| < \delta_\epsilon$, $|f(x) - b| < \epsilon$. This condition, which is frequently taken as the definition of a limit, "has to be appropriately modified in the cases where a and b are replaced by $+\infty$ or $-\infty$. The following is a necessary and sufficient condition that $Lf(x)$ shall exist and be finite: for every $\epsilon > 0$ there exists a $\delta_\epsilon > 0$, such that for x' and x'' distinct from a and such that $|x' - a| < \delta_\epsilon$ and $|x'' - a| < \delta_\epsilon$, $|f(x') - f(x'')| < \epsilon$.

The proof of these necessary and sufficient conditions and also of the following theorems must be omitted for lack of space. If $f_1(x)$ and $f_2(x)$ approach definite limiting values as x approaches a , then $f_1(x) + f_2(x)$, $f_1(x) - f_2(x)$,

and $f_1(x) \cdot f_2(x)$ approach $Lf_1(x) + Lf_2(x)$, $Lf_1(x) - Lf_2(x)$, and $Lf_1(x) \cdot Lf_2(x)$, respectively, as x approaches a ; if $Lf_2(x) \neq 0$, then $f_1(x)/f_2(x)$ approaches $Lf_1(x)/Lf_2(x)$. These propositions are evidently to be thought of also as propositions about continuous functions. To them should be added the statement that if $f_1(x)$ is continuous at $x = a$ and $f_2(y)$ is continuous at $y = f(a)$, then $f_2(f_1(x))$ is continuous at $x = a$. Also, if $f(x)$ is continuous at a point $x = a$, and if $f(a)$ is positive, then there is a neighborhood of $x = a$ upon which the function is positive.¹

In the above propositions about limits it is not necessary that $f(x)$ be defined at every point of an interval. Everything we have said about $Lf(x)$ remains valid when x takes values on any set of which a is a limit point. Indeed, in one of the most important cases, that of the summation of series (q.v.), the independent variable takes on only integral values, and $a = +\infty$. For the following theorems, however, we assume that $f(x)$ is defined at every point of an interval.

Continuous Functions.— $f(x)$ is continuous on an interval ab if it is continuous at every point of the interval; in particular, it must be continuous at a and b . One of the most famous propositions of real function theory states the principle of uniform continuity:² if ϵ is any positive number, there is a $\delta_\epsilon > 0$, such that on every interval of ab of length less than δ_ϵ the oscillation of $f(x)$ is less than ϵ . Other propositions in this connection are that a continuous function has a finite maximum value $f(x_1)$ and a finite minimum value $f(x_2)$ and takes on all intermediate values.³ An important corollary of this is that every algebraic equation of odd degree with real coefficients has one real root. If a function is monotonic and continuous, it has a monotonic and continuous inverse.

If $f_1(x)$ and $f_2(x)$ are continuous on an interval ab and if $f_1(x) = f_2(x)$ on a set everywhere dense on ab , then $f_1(x) = f_2(x)$ at every point of the interval ab . The last theorem enables us to say that if a continuous function is known at every point of an everywhere-dense subset of an interval, it is known on the whole interval. Since there are enumerable everywhere-dense subsets, a continuous function is thus capable of determination by an enumerable set of conditions. This phenomenon is also manifested in the theorem that any continuous function may be expressed as a convergent series of polynomials. Generalizations of this theorem to discontinuous functions have been obtained by R. Baire,⁴ the next class of functions beyond the continuous being those discontinuous functions which are representable by series of continuous functions.

The class of continuous functions includes as a subclass the differentiable functions, i.e., those continuous functions which possess at every point a derivative. (See CALCULUS). The existence of a derivative, which amounts to the condition that the graph of $f(x)$ shall possess a tangent, puts a limitation on the manner in which a function may oscillate.⁵ The earlier students of calculus assumed that every continuous function may be differentiated, in fact, several proofs of this statement were offered. Weierstrass⁶ was the first to give an example of a function which is everywhere continuous

and such that for no interval is it differentiable at every point.

A subclass of the differentiable functions is constituted by those functions for which the second, third and in general the n th derivatives exist. For such a function a formal expansion by means of Taylor's formula (see SERIES; CALCULUS) is always possible, but as has been shown by A. Cauchy and A. Pringsheim,¹ this series need not always converge and, if convergent, need not represent the function. A function which may be represented by Taylor's series is called analytic. Necessary and sufficient conditions for the expansibility of functions by Taylor's series have been given by Pringsheim, but the full significance of the existence of all the derivatives of a continuous function is still to be determined.

Another outstanding problem in connection with continuous functions is that of the orders of infinities and infinitesimals. A function $f(x)$ becomes infinite or infinitesimal at a point if it approaches $+\infty$, $-\infty$, or 0. If $f(x)$ and $\phi(x)$ both become infinite (or infinitesimal) at the same point, a , we may have their quotient approaching (1) more than one limit, (2) a unique finite limit, not zero, (3) zero, (4) $\pm\infty$. For the first case no extensive theory has been developed. In the second case the functions are said to be of the same order; in the third case $f(x)$ has an infinity of lower order or is infinitesimal of higher order than $\phi(x)$; in the fourth case $f(x)$ has an infinity of higher order or is an infinitesimal of lower order than $\phi(x)$. For analytic functions the notion of order is well established, for other functions not.

Discontinuous Functions.—A function may fail to be continuous at a point in several ways. In the first case, $Lf(x)$ may exist but be different from $f(a)$. In this case the discontinuity is called removable (*hebbbar*), because by modifying the value of $f(a)$ to be the same as $Lf(x)$ a continuous function is obtained. If $Lf(x)$ fails to exist, $f(x)$ may still approach definite limits from above and from below. These limits are usually indicated by $f(a+0)$ and $f(a-0)$. $f(a)$ may coincide with either of them or differ from both. All these cases are referred to as discontinuities of the first kind.¹ If $f(a+0)$ or $f(a-0)$ fails to exist, that is, if $f(x)$ approaches more than one value as x approaches a from the right or from the left, $f(x)$ is said to have a discontinuity of the second kind at $x=a$. For this to occur, $f(x)$ must have an infinity of oscillations in every neighborhood of $x=a$. Such a function is

osc $\frac{1}{x}$ in the neighborhood of $x=0$.

It is easily provable that there is a finite or infinite greatest value approached by $f(x)$ on either side of $x=a$ and likewise a finite or infinite least value approached. These four numbers are generally denoted by $\bar{f}(a+0)$, $\bar{f}(a-0)$, $\underline{f}(a+0)$, $\underline{f}(a-0)$. The differences among these four numbers and $f(a)$ give a variety of ways of defining a measure of the amount of discontinuity at a point. For example, the lower bound of the oscillation of $f(x)$ on every interval which includes $x=a$ is the difference between the greatest and the least of these five numbers and is called the oscillation of $f(x)$ at $x=a$.

In classifying discontinuous functions ac-

cording to the distributions of the points of discontinuity over an interval there are two cases of which other cases are compounds. On the one hand, are the totally discontinuous functions, i. e., functions discontinuous at every point such, for example, as the function which is $+1$ if x is a rational number and -1 if x is an irrational number. On the other hand every interval may contain a point where $f(x)$ is continuous; such a function is called point-wise discontinuous, though there is some divergence of usage in this particular.¹ A point-wise discontinuous function has the property that the points where the oscillation is greater than any fixed positive number, ϵ , constitute a nowhere-dense closed set. On considering an infinite sequence $\epsilon, \frac{\epsilon}{2}, \frac{\epsilon}{4}, \dots$ of such numbers, it is

evident that the set of points of discontinuity of a point-wise discontinuous function is an enumerable set of nowhere-dense closed sets.

The theory of discontinuous functions has received perhaps its main impetus from the study of definite integrals. (See CALCULUS). The integral of $f(x)$ between a and b , written

$$\int_a^b f(x)dx, \text{ stands for } \lim_{n \rightarrow \infty} \frac{b-a}{n} \sum_{k=0}^{n-1} f(x_k), \text{ where}$$

x_k lies between $a + \frac{k}{n}(b-a)$ and $a + \frac{k+1}{n}(b-a)$.

The function is said to be integrable if this limit exists and is unique. It is easily seen by aid of the principle of uniform continuity that every continuous function is integrable and it is also evident that a totally discontinuous function is not integrable. Riemann proved that a necessary and sufficient condition for the integrability of a discontinuous function is that the set of points at which the oscillation of $f(x)$ is greater than any positive number shall be of content zero. Thus an integrable function is continuous or so point-wise discontinuous that the set of points of discontinuity is an enumerable set of sets of content zero.

The content of a point-set is the definite integral of a function which is equal to unity for all points of the set and to zero for all other points. Corresponding to the Borel-Lebesgue generalization of content (see *Measure and Measurable Assemblages* in ASSEMBLAGES, GENERAL THEORY OF) is a generalization of the definite integral, due to Lebesgue,² which extends the notion to a very broad class of functions. This generalization has been guided largely by the aim to state the definitions of differentiation and integration in such a way that they shall be inverse operations. According to the usual definitions (see CALCULUS) this is true for a limited class of functions, but there exist, on the one hand, functions whose integrals cannot be differentiated and, on the other hand, functions whose derivatives cannot be integrated. The only effective generalization of the derivative that has been suggested in this connection is the substitution for the regular limit of $[f(x)-f(x_1)]/[x-x_1]$, one of the upper and lower bounds of the values approached by it as x approaches x_1 , from above or below.

Attempts to generalize the limiting process in various directions are characteristic of the

present tendencies in analysis. The principal results so far have been obtained in connection with infinite divergent series by Césaro, Mittag-Leffler, Borel¹² and others. Another class of problems is the solution of functional equations. For example, it is known that among continuous functions, if $f(x+y)=f(x)+f(y)$, then $f(x)=ax+b$. But is this true if the restriction of continuity be removed?

Functions of More than One Variable.—The above account has dealt entirely with functions of one variable. A single-valued function of several variables, $f(x_1, x_2, \dots, x_n)$ is a variable y such that to every set of values $(x_1, x_2, \dots, x_n)$ there corresponds one, and only one, value of y . The theory of such functions differs from that which we have been considering mainly in that the point-sets involved are no longer linear, but, rather, n dimensional. The approach to a point in a limiting process may now take place not only from two sides but by an infinity of paths. In grasping this situation, the principal idea so far advanced is that of uniform convergence (cf. SERIES). But on this subject the reader is referred to the treatises cited below.

REALF, rälf, Richard, Anglo-American poet: b. Framfield, Sussex, 14 June 1834; d.

Oakland, Cal., 28 Oct. 1878. He was the son of a rural constable and florist, and in his 17th year published a volume of crude but promising poems under the title of 'Guesses at the Beautiful.' The work was edited by Dr. Phyrne, afterward bishop of Chichester, and Realf became an idol of a circle which included Lady Byron and her daughter, Ada Lovelace; the Rev. Frederic W. Robertson, the banker-poet Rogers, the sculptor Behnes, Leigh Hunt and others. Becoming partly demented in a mysterious love affair, Lady Byron sent him to New York, where he was assistant superintendent of the Five Points House of Industry in 1855-56. Then he entered the Kansas Free-State struggle, which led him to a close connection with John Brown, by whom he was selected as Secretary of State for the new form of government he had planned for the people he expected to set free. In August 1862 he enlisted in an Illinois regiment and served under various commands till 1867. Then he passed several years in editorial work in Pittsburgh, Pa., and subsequently appeared on the lecture platform, where his 'Battle-flashes' and 'The Unwritten Story of the Martyr of Harper's Ferry' attracted wide interest. His life was a sad and strange story. He wrote some of our strongest war poems while in the army. Among his best-known productions are 'My Slain,' 'Indirection,' 'Symbolism' and 'An Old Man's Idyl.' A collection of his poems was edited by his friend Richard J. Hinton in 1899.

REALGAR, a gorgeous, aurora-red mineral, found massive and in transparent or translucent, monoclinic crystals of short prismatic habit. Its lustre is resinous, hardness 1.5 to 2; streak orange-red. Analysis shows that it contains sulphur 29.9, arsenic 70.1, yielding the formula AsS or arsenic monosulphide, though it is usually regarded as arsenic disulphide, As₂S₂. Upon exposure to light it soon disintegrates, changing to a pulverulent, orange-yellow orpiment (As₂S₃) and white arsenolite (As₂O₃). It is found massive, disseminated or crystalized in the vicinity of volcanoes and in many igneous rocks, and it occurs abundantly in fine crystals in Hungary and Transylvania. It has recently been discovered in Macedonia, at Mercur in Utah, and massive, in enormous deposits, in the State of Washington. Its previous rarity precluded its use in the manufacture of arsenious oxide, for which purpose it is now extensively mined in Washington. Artificial realgar, known as 'red orpiment' or 'ruby sulphur,' when mixed with nitre forms 'white Indian fire.'

REALISM, (1) a term in at least two fundamentally different seems in the history of philosophy. (a) During the period of scholasticism (q.v.), realism denotes the doctrine that universals have an existence which is in some sense independent of the particular things that appear to the senses. This theory is derived from Plato's doctrine of ideas, and goes back ultimately to the Socratic view that only through the concept, or universal idea, is it possible to obtain real knowledge. Plato, developing this position, maintained that the universals, as ideas, exist apart from the world of sensible appearances, and from the true and abiding reality, while the latter is merely the world of imperfect copies, the transitory and inad-

quate representations of this true world of supersensible existence. In spite of the differences in name, then, and the necessary difference of interest in the problem due to the special intellectual outlook of the times, mediæval Realism in its earlier and extreme form is identical in standpoint with Platonic Idealism. The later mediæval realists, under the criticism of nominalism (q.v.), modified the extreme view that universals exist apart from things, in the same direction in which Aristotle modified Plato's doctrine of the separate existence of ideas. That is, instead of defending the extreme proposition that universals exist prior to and independent of things (*universalia ante rem*), they maintained with Aristotle that the universal, the type or form, is an essential factor in constituting the particular an individual thing, and that the two are, therefore, always found together (*universalia in rebus*). The whole problem of the relation of the universal and the particular, as it presented itself to the scholastic mind, received its most adequate statement and solution at the hands of Thomas Aquinas. He pointed out that there is a sense in which all of the formulas that had been proposed by realists and nominalists alike are true and justifiable. We may say that the universal is prior to the thing and independent of it, inasmuch as we must suppose that the idea as a universal existed in the mind of God before particular things were created; and in this sense we may, therefore, accept the statement *universalia ante rem*. But it is the presence of universals that gives to particulars their reality, and it is through their presence in things that they are known to us; therefore, the formula *universalia in rebus* is justified. Furthermore, it is the particular, not the universal, that is first known to us. So that from the standpoint of our knowledge, we may admit the nominalistic proposition *universalia post rem*.

(b) In modern philosophy, Realism has an entirely different meaning, and is directly opposed to Idealism (q.v.). Realism in modern systems assumes many forms, just as Idealism does, and the two views approximate to each other in so-called doctrines of ideal-realism. But yet the fundamental distinction between these two types of thought remains and may be definitely stated as follows: Realism maintains that the universe is composed of a larger or smaller number of "reals" that exist in and for themselves, independently of any relation to mind. Its main historical contention has been in opposition to any theory that would reduce the world to a system of ideas. Usually the argument of the realists has been directed against the type of idealism that attempts to interpret reality in terms of the consciousness of finite individuals. But it also maintains that real things possess a being outside and in a real sense independent of the absolute experience of God. We may grant, the realist would argue, that God knows all things, yet these things are not merely his ideas, but possess a reality and independence of their own. These real things are variously conceived in the different systems. In the Scottish philosophy (founded by Thomas Reid 1710-96), we have the doctrine of "Natural Realism." That is, things are regarded as real just as they are given through immediate perception. In know-

ing, the mind deals directly with independent real things. This reality is guaranteed by "Common Sense," or the fundamental intuitions of mankind. By Kant, on the contrary, the world of perceptive experience is regarded as merely a phenomenon of consciousness. There remains for Kant, however, a world of things-in-themselves beyond experience which can never be known, but which we are necessarily obliged to think as the basis of the phenomenal world. As completely unknown and unknowable, this world of ultimate reality is incapable of any description or theoretical treatment whatever. Herbert Spencer, who speaks of his view as "Transfigured Realism," occupies fundamentally the same position as Kant. Herbert (1776-1841), while agreeing with Kant that the world of sense-experience is phenomenal and exists only for a knowing consciousness, still holds that it is possible to define and determine by means of metaphysical investigation the nature of reality in itself. He, therefore, postulates the existence of a plurality of absolute "Reals" (*Reale*), each of which is simple and unchangeable, and between which relations obtain which give rise to the phenomenal order of experience. Leibnitz (1646-1715) in his doctrine of monads, Fechner (1801-87), and Lotze (1817-81), regarded the ultimate of nature of reality to be a system of physical forms of existence or souls. At present, especially in England and America, there is an active philosophical school which calls itself and is called the New Realism. Its distinguishing characteristic is a view of the mind which finds the unity of consciousness largely or entirely in the structural relations of the system of mental states, which when combined after another fashion are not mental at all, but components of the physical universe. It is apparent that this demands a view of relationship which considers the terms of a relation as capable of entering without change into another relational context. The New Realism is usually associated with a view that true knowledge consists in an identity of structure, and possibly also of content between the state of knowledge and the object known. In England the best known adherents of this school are B. A. W. Russell and G. E. Moore. In America the New Realists comprise R. B. Perry, E. B. Holt, F. J. W. Woodbridge, W. P. Montague, W. T. Marvin, W. B. Pitkin, E. G. Spaulding, G. S. Fullerton, J. E. Boodin and E. B. McGilvary.

(2) In the fine arts and in literature, Realism is opposed by Idealism. In general, it may be said that Realism insists on correspondence with nature, on representing things as they are actually found in experience, while idealism tends toward an imaginative treatment which does not limit itself to reality as actually known. These two methods of treatment can never be absolutely exclusive of each other. In the work of any given individual one element or the other may be most prominent, but both must be present if the picture or statue or writing is to rank as an artistic production. Both in the choice of subject and in the details of his treatment the realistic artist idealizes: that is, he interprets the actual by isolating it from the context or environment in which it appears, and which serves to some extent to hide its true significance; and, secondly, he also idealizes by representing in his treatment what

is universal and essential, omitting certain things and selecting others with this end in view. On the other hand, the idealist who "bodies forth the forms of things unseen," or sings of "a light that never was on sea or land," must nevertheless be "true to nature," in the sense that his imagination must work in accordance with the laws of reality. Otherwise the result is something grotesque and fantastic. We do, however, speak of the work of any particular individual as realistic or idealistic according as the treatment shows more prominently one tendency or the other. There are three ways in which these different tendencies, or attitudes of mind, are shown in the fine arts and literature. In the choice of a subject matter, the realist selects either something actually existing, some familiar scene or well-known event, or at least, if he does not make an exact transcript of a particular object or set of occurrences, it is the concrete individual things of experience with which he deals. Idealism, aiming more directly at the representation of what is universal and typical, constructs for itself its forms and matter, choosing to express itself through a representation, it may be, of angels, Graces or Madonnas, or through a literary portrayal of events and occurrences of some past time that admits of free imaginative treatment. This difference in choice of subject matter also carries with it important variations in manner of portrayal. As realism aims more directly than idealism at correspondence with nature, it is clear that it must emphasize to a greater extent fullness and accuracy of detail. But there is also difference in the kind of detail that is chosen, and in the emphasis that is given to details of different characters. As it is the object of realism to represent its subject matter in concrete, individual form, the details which are essential to produce this impression are naturally emphasized. An idealistic treatment, on the other hand, seeking to represent more directly the universal and essential, necessarily gives an entirely different value to the various details, omitting, it may be, much that would be regarded as essential in the school of realism and giving a prominent place to what the latter might keep in the background. It is false art and a false realism, however, that emphasizes what is ugly, unpleasant and pathological in such a way as to make these the most prominent features of the total work. This realism has rightly been held to be characteristic of a decadent art, of an art that is inevitably suicidal. For the real, which it is the business of art to reveal and portray, in nature and in human nature alike, is the universal, the abiding and hence the normal; what is diseased and monstrous are necessarily particular and transient and, therefore, not real in the fullest sense. Art, like all conscious activity, can only live so long as it assumes that what is rational in the fullest sense must be that which is in the deepest sense real. See IDEALISM.

JAMES E. CREIGHTON,

Professor of Logic and Metaphysics, Cornell University.

REALISM AND NATURALISM IN LITERATURE. Realism in literature means that the writer represents persons, scenes, things, and facts as they are, life as it is. The word is used in many senses—as opposed to romanticism, to conventionalism, to sentimentalism, to idealism, and to imaginative treatment. Sometimes it is a term of praise, in cases in which precision and vividness of detail are considered meritorious; sometimes it is used as a term of reproach as, for example, when it is contrasted with idealized description or representation. In modern times, and in particular during the greater part of the 19th century and the earlier years of the 20th, the use of the word realism has often implied that the details brought out were of an unpleasant, sordid, obscene, or generally offensive character. Naturalism in literature should mean a style or method of writing characterized by close adherence to, or faithful representation of, nature; but, in the hands of its most notorious modern exponents, it quickly degenerated into a connotation of the more sinister features of realism. Thus a writer in the *London Daily News*, in June 1881, speaks of "That unnecessarily faithful portrayal of offensive incidents for which M. Zola has found the new name of 'Naturalism.'" This "new name" soon thereafter became a technical term to denote that remarkable outflowing of realism which predominated in French and other literatures for some 35 years from about 1860. It is obvious that in essence a distinction may properly be made between realism and naturalism as the words have come to be used. In practice, however, they are often regarded as one and the same thing, and in this article they may conveniently be treated together, although, in the course of it, it may be necessary from time to time to draw attention to the difference which actually exists.

In recent usage, the term realistic is technically applied to a 19th century school of writers; but realism, in its prime and proper sense, is as old as literature itself. We find it in Homer and Aristophanes; in the Old Testament; in the ancient Egyptian writings; in the earliest Saga literature of the Norse peoples; in the Indian, Japanese, and Chinese rogue stories of the 6th, 10th, and 13th century, respectively; in the mediæval Fabliaux; in Boccaccio and Chaucer; in the picaresque novels of Spain; in the Elizabethans; in Rabelais, Cervantes, and Voltaire; in Aphra Behn and Bunyan; in Richardson, Fielding, and Smollett as well as in Swift and Defoe. Realism was a pronounced feature of some of the later Greek

and Latin literature. Thus Lucian (b. c. 120 A.D.), in satirizing, in his 'True Story,' the extravagances of Eastern Greek romance, gives us himself very realistic details side by side with many a romantic and impossible adventure, and he is even more outspoken in 'The Carousal' and in 'Lucius, or the Ass,' if indeed he is truly the author of the last-mentioned work. Still more realistic in aim is the African Lucius Apuleius (b. c. 125 A.D.) in his 'Metamorphoses, or Golden Ass,' written in Latin. Unrestrained realism is exhibited by Gaius Petronius Arbiter (1st century A. D.) in his 'Satiricon,' in which he describes the debauched and dissolute condition of Roman society during the early empire.

While the modern realistic novel may be said to take its remote origin from the Spanish 'Lazarillo de Tormes' (1553), the first of a great number of picaresque, or rogue, stories—the begetters of Thomas Nash's 'Unfortunate Traveller, or Jack Wilton' (1594) and Richard Head's 'The English Rogue' (1665), in England, and of Sorrell's 'Francion' (1622), Scarron's 'Roman comique' (1651-57), Furetière's 'Roman bourgeois' (1666), and Lesage's 'Gil Blas' (1715), in France—it is nevertheless the fact that the realism which sprang up in France early in the 19th century and afterward spread to other countries—England, Spain, Germany, the United States of America—was primarily a protest against romanticism. It may perhaps be reasonably said to derive, directly or indirectly, from Jean Jacques Rousseau, who, in his 'Confessions,' had taken care that the whole of male experience, even in things considered shameful and wicked and therefore usually kept secret, was revealed to an attentive world. Leaving out of account the practically isolated case of the 18th century Nicolas Edme Restif (1734-1806), known as Restif de la Bretonne and sometimes called 'the Defoe of France,' sometimes 'the Rousseau of the gutter,' we shall probably be chronologically correct in saying that the newer phase of realism began with Charles Paul de Kock (1794-1871), a master of the art of working up an interesting story by the use of simple and commonplace details, gathered from observation at first hand. He was author of about 100 works, the best known of which are perhaps 'Gustave le mauvais sujet' (1821), 'Le barbier de Paris' (1826), 'La laitière de Montfermeil' (1827), and 'André le Savoyard.' Although 'Le barbier de Paris' was translated into nearly every European language, de Kock, owing to a poor style—he was of Dutch descent—and a certain aloofness from literary and political movements, exercised no great influence on his French fellow-countrymen. The first of the 19th century realists to do that was Marie Henri Beyle (1783-1842), known as Stendhal, who, in 'Armance' (1827), 'Le rouge et le noir' (1831), and 'La chartreuse de Parme' (1839), put forth vivid studies of social types, brimful of energy and passion. He was soon followed by Honoré de Balzac (1799-1850), the novels of whose 'La comédie humaine' (1829-47), while ideal in conception, aimed to be real in detail—"human documents," in fact—and shrank from the fullest exposition of neither vice nor passion. Next came Gustave Flaubert (1821-80), who, according to Zola, gave, in 'Madame Bovary' (1857), the formula of the

modern novel. 'Madame Bovary,' a close and minute study of provincial bourgeois life, is the epic of the commonplace, and was meant to be, as it certainly is, a bitter satire on the last exaggerations of romanticism. In 'Salammbô' (1862), a study in epic realism, Flaubert applied the same method to the civilization of ancient Carthage, and he continued it in his celebrated picture of Paris life, 'L'Éducation sentimentale' (1869) and in his pessimistic 'La tentation de Saint-Antoine' (1874). There is no doubt that Flaubert made a profound impression upon his own age. Yet it is a strange commentary on his professed efforts that one of the keenest of modern French critics, Ferdinand Brunetière, decided that, while Flaubert was a master by as just a title as Balzac, and a far greater stylist, he still was a romanticist at heart. To a certain extent, his 'Trois Contes' (1877) might be adduced in justification of that opinion.

Soon after the appearance of the second of Flaubert's great works, Taine, by publishing 'Le Positivisme anglais: J. St. Mill' (1864), in which he gave an excellent summary and criticism of Mill's 'Logic,' with its insistence on the collection of attributes and on detailed description, supplied, for the assimilation of the materialistic philosophy and its application to literature, a medium and a technique of which his compatriots were not slow to avail themselves. This method, joined to the scientific sensualism which Comte had established, and Renan had developed, under the name of Positivism, rapidly became a working theory for the adventurous litterateur. From that time onward the collection of data of a biological and sociological kind, or, in other words, of detailed information concerning heredity and environment, became for many French novelists the basic principle for the study, creation, and development of character. The brothers de Goncourt (Edmond, 1822-96 and Jules, 1830-70) in 'Germinie Lacerteux' (1865) immediately put into practice that minuteness of observation and that reporter-like assemblage of facts which was to become a special characteristic of the new realistic, or, as it now began to be called, naturalistic school. In 'Manette Salomon' (1867) and 'Madame Gervaisais' (1869) they jointly continued the method, in which, in 'La fille Elisa' (1878) and other novels, Edmond persevered for many years after his brother's death. Of the new school the de Goncourts regarded themselves as the legitimate heads, and Émile Zola (1840-1902) as their most promising disciple, with Henri Céard, Joris-Karl Huysmans, Léon Hennique, Guy de Maupassant, and a host of others as lesser satellites. Of these, de Maupassant, while remaining a naturalist, outgrew the circle in virtue of his native genius. Huysmans, in 'Marthe' (1876), a study in sordid prostitution, gave a striking example of the naturalistic, as distinct from the merely realistic, novel. Zola, however, speedily became the high-priest of the cult, the protagonist and propagandist of a savage naturalism. His theory of the experimental novel, as he called it, was that it "is a consequence of the scientific evolution of the age; it continues and completes the work of the physiologist," although he rather nullified this position when he laid down the definition that "the realistic novel is a corner of Nature

seen through a temperament.⁹ He had been publishing since 1864. His series of 20 novels, produced under the collective title 'Les Rougon-Macquart' (1871-93) and including 'Le ventre de Paris' (1873); 'L'Assommoir' (1877), and 'Nana' (1880), are tainted with a grossness against which there were loud outcries, but many of them, just on account of that grossness, had an enormous circulation. When 'La terre,' which appeared to pass all limits of decency, came out in 1887, even Zola's own disciples joined in its condemnation. Soon afterward, while realism remained the inspiration of most French fiction, naturalism began to decline, and when Zola died in 1902 he had survived by nearly a decade the movement of which he had been the chief exponent and spokesman. Alphonse Daudet (1840-97), a writer who also aimed to describe life as it is, was certainly influenced by the naturalistic school in 'Sapho' (1884), but on the whole he stands apart from naturalism. Paul Bourget (b. 1852) endeavored, in 'Mensonges' (1887) and other works, to carry realistic observation beyond mere externals into what he called "states of the soul."

In Russia, Nikolai Gogol (1809-52), with 'Old World Proprietors' and 'How the two Ivans quarreled' (1835), minute studies of life in the Ukrainian villages, had already anticipated much of the "human document" theory and practice, and realism was still further illustrated by the novelists Gontcharov (1812-91), Turgenev (1818-83), Dostoyevsky (1821-81), and Tolstoy (1828-1910), and by dramatists like Ostrovsky (1823-86). Realism is by no means a spent force in Russia, as witness Artsybashev's 'Sanin' (1907), Chapygin's 'The White Hermitage' (1913), Shmelev's 'The Man from the Restaurant' (1913), Kuprin's 'The Pit,' the naturalistic short-stories of Korolenko and Potapenko, and the underworld tales of Maxim Gorky. Realism entered Germany from both France and Russia. Its principal exponents were Max Kretzer (b. 1854), sometimes known as "the German Zola," with his socialistic novel 'Meister Timpe' (1888); Hermann Sudermann (b. 1857), with 'Der Katzensteg' (1889) and 'Iolanthes Hochzeit' (1893); Gerhart Hauptmann (b. 1862), with his dramas, 'Vor Sonnenaufgang' (1889), 'Das Friedensfest' (1890), and 'Rose Bernd' (1903); and Max Halbe (b. 1865), with his dramas, 'Jugend' (1893) and 'Mutter Erde' (1897). In Sweden, Karl Almqvist (1793-1866) was in the main a romanticist, but his later work, 'It's All Right,' a grim picture of the evils of conventional marriage, is in the realistic vein. August Strindberg (1849-1912) produced in 'The Red Room' (1879) what was at that period in Sweden a startlingly realistic novel, and in his novel, 'Marriage' (1884-86), and his dramas, 'The Father' and 'Miss Julia,' he aimed to be both realistic and naturalistic. In Norway, Bjørnstjerne Bjørnson (1832-1910), beginning with works of a lyric and romantic-religious character, produced in 'The Newly Wedded Pair' (1866) a realistic problem play, and in a long series of dramas and novels from 1874 to 1889 he exhibits the same realistic and analytic tendencies. Ibsen is also a realist, but he is a great deal more, for his works are, as a rule, too subtly complicated and too spiritual to be

reducible to one classification. In Italy, Mathilde Serao (b. 1856) and, especially, Gabriele d'Annunzio (b. 1864), with his pagan sensualism, are perhaps the best-known representatives of the realistic school. In Spain, José María de Pereda (1833-1906) was the pioneer modern realist, and he was followed by Benito Pérez Galdós (b. 1845), Armando Palacio Valdés (b. 1853), and Emilia, Countess of Pardo Bazán (Señora Quiroga, b. 1851). Juan Valera (1824-1905), though not technically a realist, but rather tending consciously toward idealism in his novels, is, for all that, none the less real. In England, Henry Fielding (1707-54) insisted that the novel should show real life, and in his practice he found many 18th century imitators. In the 19th and 20th centuries among the great realistic novelists are Jane Austen (1775-1817), William Makepeace Thackeray (1811-63), Charles Dickens (1812-70), "George Eliot" (1819-80), George Meredith (1828-1909), Thomas Hardy (b. 1840), George Moore (b. 1853), Herbert George Wells (b. 1866), John Galsworthy (b. 1867), and Arnold Bennett (b. 1867). Realistic dramatists are Sir Arthur Wing Pinero (b. 1855) and George Bernard Shaw (b. 1856). Many of the modern Hiberno-English novelists and dramatists are starkly realistic, and one or two of them frankly naturalistic. In the United States of America many realistic writers sprang up in the wake of the propaganda which William Dean Howells (b. 1837), under the influence of Tolstoy, Valdés, and Galdós, carried on for many months in *Harper's Magazine*. The principal American realists are Howells himself, who may be looked on as the creator of the American novel of character as distinct from the novel of incident, Henry James (1843-1916) with his subtle psychology and his peculiar style, Hjalmar Hjorth Boyesen (1848-1905), and Paul Leicester Ford (1865-1902).

In poetry realism has not had so much sway as in the novel or the drama. Poetic realism is mainly impressionistic and tends to symbolism. It is found more or less developed in some of the poems of the German Arno Holz (b. 1863) and the French Paul Verlaine (1844-96), and it is the motive power of many of the writers of modern *vers libre* of all countries, especially when they record the impressions of observed phenomena.

The recent tendency has in general been away from crude naturalism to a saner and soberer realism. Truthful portraiture is desirable in literature, and in so far as realism and even naturalism supply solid and stabilizing literary elements they are to be commended. The high seriousness of much of modern fiction is attained by a proper use of such elements. It is against the abuse of the genre that the true artist, no less than the moralist, must always protest.

REALSCHULEN, rä-äl'shoo-lën, a class of institutions in the German system of secondary education characterized by the emphasis laid upon the study of the sciences, mathematics and modern languages as opposed to the gymnasia in which the classics constitute the principal feature of the curriculum. The Realschule took its rise in Germany in the early part of the 18th century, but did not attain its full development until the second half of the 19th century, when the tremendous progress of science compelled, after a long struggle, the recognition of this type of school as of equal rank with the gymnasia in the national system of education. In the struggle, however, between the classical school and the scientific school a mixed form was developed, approaching more nearly to the Realschule in the importance attached to the non-humanistic branches, but including Latin in its lists of studies. This type of school is known as the Real-gymnasium, and between it and the gymnasia the differences are growing less every year, especially since the study of Greek in the Prussian gymnasia was rendered non-obligatory in 1900. Real-gymnasias are, however, included under the general designation of Realschulen, a term which, in its broadest signification, includes the following classes: (1) *Oberrealschulen* (Upper Real schools), scientific schools with a nine years' course, giving no instruction in the ancient languages; (2) *Realgymnasien* (Real-gymnasias), scientific schools with a nine years' course, giving instruction in Latin; (3) *Realschulen* (in a stricter sense), the same as the *Oberrealschulen*, without the highest class; (4) *Realprogymnasien*, bearing the same relation to the *Realgymnasien* as the *Realschulen* to the *Oberrealschulen*; and (5) *Höhere Bürgerschulen* (higher middle schools), offering a six years' course without Latin. While the Real-gymnasium has been approaching the classical school in character,

the Real-schools proper have been extending their scope so as to include various forms of technical and even industrial education. Graduates of Real-schools are ineligible for admission to various departments and faculties in the universities, the most liberal conditions prevailing in Prussia, where only the faculty of theology is closed to them. See GERMANY; EDUCATION; GYMNASIA, and consult Bolton, F. E., 'The Secondary School System of Germany' (New York 1900); and Russell, J. E., 'German Higher Schools' ib. 1907).

REALTY and the terms real property and real estate denote the interest one has in lands; it applies not only to ground but to everything which is attached or a part of it, as trees, stones, houses or other structures. Timber, grain and grass rooted to the soil are realty, though when severed they become personalty. Any crop which is an annual product of the soil when ripe is considered as personal property. Permanent buildings erected on one's land without permission become the property of the owner of such land, without regard to the ownership of the materials. Fixtures or things which have been attached to the realty and cannot be removed without injury to it, or which have become so adapted to the building or land as to be necessary to its use, are considered a part of the realty. In addition to the elements of realty which have been above described, are rights which are connected therewith, such for example as a right of way, a right to the use of a water course and easements. An uninterrupted use of any easement or right for 20 years or any less period fixed by statute raises presumption of title. The various estates which one may possess in realty had their origin in the feudal system of England, the fundamental principle of which is that the king was the original proprietor of all the land in his kingdom, and no one came into any part of it except by gift from him, or in return for feudal services, and thus the land was divided among a graded body of owners beginning with the king's noblemen. In the United States all the instances of feudal tenure have been abolished. In Canada the tenure by which land is held varies in the different provinces, some being largely regulated by a statute enacted during the reign of George III.

Title has been defined as a means whereby the owner of lands has the just possession of his property; title may be acquired by descent, that is, through the death of an ancestor, by purchase or by operation of law. The legal title of land is usually transferred from one person to another by means of a deed, the many essentials of which are fixed by the statutes in various jurisdictions.

The assessed valuation of real property in the United States in 1916 was \$51,159,000,000, of which more than one-fifth (\$11,146,000,000) was in New York State, and nearly one-tenth (\$5,088,000,000) in New York City. Estimates of the actual value vary between \$100,000,000,000 and \$200,000,000,000.

REAM, Norman Bruce, American financier: b. Somerset County, Pa., 5 Nov. 1844: d. 9 Feb. 1915. He was educated in the public and normal schools, and in 1861 enlisted as a private in the 85th Pennsylvania Volunteers. He was promoted lieutenant and served until

invalided out of service after being wounded in action near Savannah. He afterward engaged in the live-stock and grain commission business in Chicago and became one of the principal figures in the Chicago market. He was connected with the Armour's in their corner of the pork market in 1879 and in 1883 assisted in averting a collapse in the grain market. He was active in the organization of the National Biscuit Company and the United States Steel Corporation. After 1888 he devoted himself to his real estate, manufacturing and railroad interests and served as director of many railroads, banks and trust companies.

REAM'S STATION, Battle of. As the extension of General Grant's left to Globe Tavern on the Weldon Railroad (see **GLOBE TAVERN, BATTLE OF**) did not prevent General Lee's use of the road as a line of supply up to a point within a day's wagoning to Petersburg, General Grant determined to destroy the road as far down as Rowanty Creek, 13 miles beyond Globe Tavern. On 22 Aug. 1864 General Hancock, with Miles' and Gibbon's divisions of the Second corps and General Gregg's cavalry division, in all about 8,500 men, moved to the left and by night of the 24th had destroyed the road from Globe Tavern to a point three miles south of Ream's Station and 12 miles from Petersburg. During the 24th Gregg's cavalry was sharply attacked by General Butler's division of Confederate cavalry, and at night General Meade informed Hancock that Confederate infantry was moving in his direction, but as yet none had been seen by Hancock. At daylight of the 25th a cavalry reconnaissance drove in the Confederate pickets and Gibbon was ordered to move out from Ream's Station and complete the destruction of the road. Gibbon had hardly gotten well on the road, when the Union cavalry was driven in by cavalry supported by infantry and he was obliged to deploy a strong skirmish line to check the enemy in pursuit. Prisoners taken from three of Gen. A. P. Hill's divisions showed that the Confederates were in strong force and Gibbon was ordered back to the Ream's Station intrenchments, where he arrived at 10 A.M. and united with Miles' division. The intrenchments were very light and had been hurriedly thrown up by Gen. James H. Wilson in his cavalry fight near that place late in the preceding June. They ran along the railroad about 700 yards and then were drawn back on the right and left about 800 or 900 yards, at nearly right angles. Both flanks were exposed to reverse fire from the front. Miles held the right half of these works, Gibbon the left half. Gregg's cavalry held the approaches in the direction of Petersburg and Dinwiddie Court House. When Hancock's movement became known to the Confederates, Gen. A. P. Hill with the larger part of his corps, together with G. T. Anderson's brigade of Longstreet's corps and Gen. Wade Hampton's two cavalry divisions, marched to prevent the destruction of the railroad, and at 2 P.M. of the 25th General Wilcox's division made two attacks upon Miles, which were repulsed, leaving killed and wounded within a few yards of Miles' front. At 5 P.M. Hill opened a heavy artillery fire and, at the end of 15 minutes, Generals Heth and Wilcox, with five brigades and three regi-

ments, made another assault upon Miles and a part of his line, held by raw recruits, gave way, abandoning a battery. At the same time the right of Gibbon's line gave way and two more batteries fell into possession of the Confederates. Gibbon was ordered to retake his lost ground, but his troops, many of whom were new recruits and drafted men, responded feebly and fell back under the first fire. Miles rallied the 61st New York and by desperate fighting retook a part of his line and his lost battery. Hampton's cavalry now attacked Gibbon and drove him entirely from his works, but was checked by a heavy flank fire from Gregg's dismounted cavalry, upon which Hampton turned on Gregg and forced him back to the left of a line which Gibbon had established a short distance in rear of the intrenchments from which he had been driven. An effort made to retake the intrenchments failed because of the inability of the Union commanders to induce their men to go forward. At dark Hancock withdrew from the field. General Hill made no attempt to follow up his advantage, but returned to the Petersburg intrenchments, leaving Hampton's cavalry at Ream's Station. The Union loss was 669 killed and wounded and 2,073 captured or missing, together with 12 stands of colors and nine guns. The Confederate loss, as reported by Hill, was 720, chiefly, if not entirely, killed and wounded. Consult 'Official Records' (Vol. XLII); Humphreys, 'The Virginia Campaign of 1864-65'; Walker, 'History of the Second Army Corps'; The Century Company's 'Battles and Leaders of the Civil War' (Vol. IV).

E. A. CARMAN.

REAPERS AND BINDERS. Technically the "reaper" is a grain harvesting machine which, in addition to cutting down the grain, gathers it into bunches ready for tying into sheaves. Speaking generally, however, the mowing machine is classed as a reaper, along with the sickle and scythe and other such simple implements. The scythe, when provided with a cradle, may be regarded as the earliest type of reaper. The first machine for reaping which actually accomplished the task was that of Henry Ogle, invented in 1826. It consisted of a straight scythe blade which ran back and forth at the rear angles of a series of triangular fingers. The cut grain fell upon a collecting board and was raked off at intervals by a workman walking beside the machine. In 1826 the Rev. Patrick Bell constructed a machine in which a number of blades on the cutting bar worked with a scissors action. At a slow speed this machine was quite effective. The first machine of the type, which is now universal, was invented in America by C. H. McCormick, who patented it in 1834. Another patent had been issued in 1833 to Obed Hussey, but the manufacture of these machines in quantity did not begin until 1845, when 150 were built by a Cincinnati firm. As many more were built in the following year. From this time onward inventors busied themselves with varying models, so that in 1852, at a contest held at Geneva, N. Y., nine different machines were entered by as many manufacturers. Compared with the highly refined reapers of the present day these machines were all exceedingly clumsy and required an excessive amount

Binder Head

Type of Knotter

of power to operate them. Not one of them could be started in standing grain; the machine had to be backed up on clear ground to get the mechanism under way before the knives entered the grain. However, improvement was rapid and production increasingly large, and by 1855 nearly 10,000 of these machines were in use on the farms of the country. It is a matter of much interest to note that the American "mower and reaper" as it was called, at the French Exposition of 1855, in contest with French and English machines, cut three times the area in the same time as the French machine and three and one-fourth times the area cut by the English machine. A number of new models were brought out, and in 1857 at the New York State Fair at Syracuse 19 different machines were entered for competition, and of these only three were unable to start in standing grain.

These mowers and reapers were fitted with a revolving reel or rack of "wipers" which swept the grain firmly against the advance of the cutter, gathered the cut grain on a table and shoved it off automatically when enough had been gathered to make a sheaf of the desired size. The tying was done by laborers following the machine. The next development was the Marsh "harvester," having a platform on which two men rode and tied the bundles of grain as they accumulated. In 1870 the self-binding reaper was invented, in which the bundles of grain were tied with wire. This machine fell into great disfavor after bits of the wire amongst the grain had destroyed valuable mill-stones. The twine binder came into use in 1875, through the adaptation of a tying device invented in 1859 by John F. Appleby, who later went into the army and forgot all about it until he had invented a new rifle. The Appleby binder on the Marsh machine offered the first perfect reaper.

Reaping machines include three classes — manual delivery, self-raking and self-binding machines. The manual delivery is but little used now except on small holdings or when a mowing machine is converted into a reaper by being fitted with a sheafing attachment. In very hilly districts the light draught of the manual delivery machine makes it a convenient machine to work, and as at high altitudes it is often injudicious to bind the sheaf at once, as drying is impeded thereby, it may be the most profitable machine to use. On the large farm it has its place for cutting out badly storm-broken patches where bigger and heavier machines cannot be conveniently used. The ordinary manual-delivery reaper differs little from the grass mower, except that it is not necessary for it to be so highly geared and that it is provided with a sheafing rack. The operator keeps up a continuous sweeping motion, pulling the crop on to the knives and loading it on the sheafing rack, which during the time it is being loaded is brought to a somewhat vertical position, being held there by a lever controlled by the operator's foot; when loaded, the rack is allowed to fall and the sheaf slips off. The self-raking machine has a platform in the form

of a quarter circle, to which the grain is reeled by the rakes, as well as removed to one side far enough to clear a fresh horse walk for the next round. The cutting bar and knives are like those of the harvester. Like the manual-delivery machine this type has but a limited use because of the fact that the grain remains unbound. For buckwheat and peas it is a favorite in some regions. It cuts usually a swath of five-foot width, requires two horses and harvests from six to eight acres per day.

The self-binding reaper, the one in most general use, consists essentially of a large traveling wheel acting as the driving wheel, which carries the framework and about and above which are the various gearings and parts necessary for sheafing and binding, and of a smaller ground wheel on the off side of the cutting plat-

Reaper (complete machine).

form. The power is distributed from the driver to the various parts by gearing or sprocket chains. The cutting parts are very similar to those of the ordinary reaper or mower, of the serrated reciprocating knife type, driven by a Pitman rod from a crank and having the usual split fingers or guards on the bar to hold the grain while it is being cut by the sliding out of the bar. The cut grain falls upon a horizontal platform, about which is an endless canvas; the latter conveys the grain to two vertical canvases parallel to one another and moving in different directions. By these the grain is elevated and conveyed to the sheafing platform. The mechanism on the sheafing platform collects the grain as it is being constantly poured upon it and separates it into sheaves; next a binder attachment binds the sheaves and releases them, allowing them to fall straight to the ground, or, as is now more common, upon a carrier which collects a number before depositing them in convenient lots to be shocked or stooked. In binders made without vertical canvases the crop is conveyed by the platform canvas directly to the packing arms and is then gripped by the grasper carrying the twine and tied. The sheaf is lifted by a mechanical fork or arm and placed outside the horse-walk for

the next round. A few years ago five-foot cuts were common with six-foot cut machines a close second. At the present time, however, seven-foot cut machines are in highest favor, and there are also a large number of eight-foot cut machines at work. The eight-foot cut is a four-horse machine and it is advisable to put this number to a seven-foot binder. If one has as much as 30 acres of grain to harvest each year, the eight-foot machine will be found economical.

Some writers have claimed that the self-binder is not profitable on a farm where less than 30 acres of grain are grown annually, although they admit that during the average life of these machines they will reap and bind about 2,000 acres. In actual practice, however,

Binder (complete machine).

it is demonstrated every season that a self-binder is profitable, other things being equal, on a farm where 10 or more acres of grain are harvested yearly. Progressive farmers usually approach the binder proposition as follows: An initial investment of \$125 at least for a three-horse self-binder; interest on this investment at 6 per cent; depreciation and repairs, 10 per cent: thus cost of binder, \$125; annual interest at 6 per cent, \$7.50; depreciation and repairs, 10 per cent, \$12.50. According to this estimate the annual cost of the binder is \$20, or \$2 per acre for reaping and binding 10 acres of grain, exclusive of the cost of binder twine, man, horse or tractor labor. If more than 10 acres are to be reaped the corresponding cost per acre is lower and the greater the number of days the binder is at work the greater the return on the investment. To secure the latter it is not uncommon for a farmer owning a binder to reap his neighbors' grain in addition to his own at a price running from \$1.50 to \$2.50 per acre, in which case the reaper investment may be turned into an income producer instead of a liability. Another plan becoming general in regions of small farms is for two or more adjoining landholders to purchase a reaper jointly.

In western United States and in Australia a binder is used. The machine is an adaptation of the binder with cutter bar, knives, platform and reel similar to the latter. It is pushed ahead of the team of from four to six horses and cuts a strip of from 12 to 20 feet. The

ears of grain are cut off and are then raised to wagons drawn alongside the header. A combined header and thresher is also in common use, by which the grain is cut, threshed and placed in sacks. Some of the larger types of header and thresher in use on the prairies have a capacity of 100 acres per day.

In Australia and other sections where the climate is very dry and the straw dries to brittleness, a reaper of different design is in favor. It has long comb-like teeth which strip the grain from the stalk, passing it into a mechanism which by a rubbing motion divests it of the husk and it is then winnowed, and on some large machines is ground as the harvesting proceeds.

REAR (from old French *arere*, modern *arrière*, mediæval Latin *ad retro*, to the back, backward), the hinderpart, or the part that comes last in order, of anything. A particular military or naval term as opposed to 'van' abbreviated from vanguard, derived from the French *avant*, in front.

REAR GUARD, a body of troops detailed to protect the rear of a marching column. It is organized like an advance guard reversed, consisting, from front to rear, of reserve, support, rear party, rear point, rear cavalry. From the reserve to the point the units decrease in size. The distances between units are approximately the same as those between the corresponding units of an advance guard, i.e., in the case of a division, say one, or two miles from the main body to the reserve, 1,000 yards between the reserve and the support, 500 yards between the support proper and the rear party, 500 yards between the rear party and the point and about four or five miles between the point of the infantry and that of the rear cavalry. Rear guards will often have to be stronger than advance guards, for they are likely to cover defeated retreating troops, which obtain time to reorganize. They should hold a succession of strong positions in such a manner as to delay the enemy as much as possible without suffering overwhelming losses, but should sacrifice themselves for the main body, if this is the only way of delaying the enemy. They,

1 Mowing-Machine attached to Medium-powered Tractor
2 Modern Reaper and Binder drawn by Tractor (Daily capacity about 10 acres)

1 Modern Reaper and Binder with Tractor as Motive Power
2 Nine Tractor-Drawn Reapers with a daily capacity of 90 acres

therefore, need to be mobile and consist largely of cavalry; engineers are also useful for demolitions; advancing troops may need rear guards in hostile territory; these march behind the trains. See ADVANCE GUARDS.

REARHORSE. See MANTIS.

REARICK, Peter Anton, American naval officer: b. Maryland, 12 Nov. 1838; d. Washington, D. C., 9 Feb. 1901. He entered the navy in 1860, was appointed third assistant engineer and served through the Civil War with promotion, becoming first assistant engineer in 1864. After the war he was on duty with the Pacific squadron on the north and south Atlantic, on European and Asiatic stations, at various navy yards and as a member of the steel inspection board. In 1874 he was made chief engineer and served in that capacity until 1900, when he was retired with rank of rear-admiral.

REASONING, or INFERENCE, is the mental process in which we advance from some known fact or principle to the truth of some other fact which is different from the starting-point. The basis for the transition is always found in the knowledge from which we set out. This is taken or assumed to be real, and in it is found the ground and justification for the advance to something else. The differentia of reasoning thus appears to be mediation; when we reason we infer that something is true *because* something else is true. Knowledge derived from reasoning may, therefore, be termed *mediate*, as opposed to the *immediate* knowledge obtained from sense perception and memory. The question at once arises how any mental content can justify an advance to something different from itself? How are we ever warranted in passing from the known to the unknown? This is not merely the question that Mill raised as to whether all syllogistic reasoning — all advance from premises to conclusion — was not a *petitio principii*; but it concerns all reasoning, inductive and deductive alike. The dilemma is that if the result is not contained in the starting-point the advance does not seem to be justified; if it is already present, the reasoning shows nothing new. The view of Leibnitz was that all reasoning is analysis, a drawing out and fuller explication of the original datum of the mind. Kant pointed out that thinking involves also synthesis, new constructions and additions to the material from which it starts, and he takes as the fundamental problem of his 'Critique of Pure Reason' the question how such synthetic judgments are possible. His answer is essentially identical with that which Aristotle gave, namely, that the mind or reason (*νοῦς*) itself enters into the process as a premise — or, in other words, that it is through the creative activity of the mind that the new truth is reached. Whether or not one can connect one fact with another in a logical way depends upon one's intellectual ability to discover points of essential resemblance or identity between facts. The good reasoner is he who can look beneath the surface and detect identities that are not at once obvious, as Newton, for example, did when he reasoned from the fall of the apple to the movements of the heavenly bodies. Reasoning, then, may be de-

fined as the process of discovering essential resemblances or points of identity between things.

It follows from what has been said that reasoning is not a process or function of mind that can go on apart from experience. The thinkers of the modern period down almost to the end of the 18th century continued to believe that reason was a kind of special organ or faculty that could yield truth of the highest order of certainty quite apart from ordinary experience. It was Kant who first clearly and incontestably showed the impossibility of deriving knowledge from reason taken in abstraction from ordinary sense experience. Kant, however, uses the term "Understanding" (*Verstand*) for the thinking faculties as employed in interpreting experience, and reserves the name "Reason" (*Vernunft*) for the vain and illusory attempt of thought to operate in independence of any given material of experience. Apart from this terminology, however, which has not been generally followed, the result of Kant's teaching was to exhibit the close and essential connection that exists between thinking and sense-perception: on the one hand, thought is empty apart from the material of sense-perception, and, on the other, what we call ordinary perceptive experience is constantly interwoven with more or less explicit processes of reasoning. Reasoning does not go on in a vacuum, nor is it a separate and distinct function of mind that in some mysterious way spins truth out of itself. But reason is on one side a universal function of receptivity; it receives its material from every channel of experience, and is itself just the unifying, co-ordinating and systematizing life of experience. Deduction and induction are often spoken of as if they were distinct species of reasoning. Reasoning, however, is always one and the same process. It consists, as we have seen, in connecting parts of experience by the discovery of some identical element in them. This identity, as present in various particulars, we may speak of as a universal, or general, principle, and, therefore, say that when we reason we unite particulars through a general law or principle. Now, the difference between deduction and induction is a difference in the starting-point and in the direction in which we proceed. If we are already in possession of the general law, and set out to apply it to particular cases, we are using deduction. If, however, our starting-point is the particular instances, then we reason inductively to discover the universal law of connection. In both cases the structure of the completed inference is the same, and consists in the connection of particulars, in virtue of our insight into the universal law or principle expressed in them.

In this reference to a universal principle, we have also that which distinguishes reasoning from the transition from idea to idea of the associative process. In a large part of the conscious life that usually is described as thinking, one idea by its very presence seems to call up another, without the apprehension of any universal or essential law of connection. But this is mere drifting on the part of the mind. In reasoning, the mind is fully awake; it sets a definite purpose before it, and proceeds by active attention and analysis to discover essential and necessary points of connection. It thus uses association for its own purposes; so that if

we define reasoning as a process of association, we must add that it is association guided and controlled at every step by the purposes of thought itself. How conscious and explicit must this direction be before we can call the process reasoning? Can animals properly be said to reason? These questions do not admit of any off-hand answer. The conscious direction of the mind, the clearness with which it apprehends the universal in the particular, is a matter of degree. We may say that some direction on the part of the mind there must be, as well as some apprehension of the terms as universal, if reasoning is to occur, without attempting to determine just when these conditions are fulfilled in any individual mind or in any species. What we call conscious reasoning is doubtless continuous with associative and instinctive mental processes that seem entirely mechanical and irrational, and the connection between the two extremes may be mediated by actually observable processes. This continuity, however, gives no justification for refusing to regard the differences as important, or for explaining either extreme of the process in terms of the other. See DEDUCTION; INDUCTION; LOGIC.

Review*, Vol. V 1898); see also the bibliography under Logic.

J. E. CREIGHTON,
Professor of Logic and Metaphysics, Cornell University.

RÉAUMUR, rā-ō-mūr, René Antoine Ferchault de, French physicist: b. La Rochelle, 28 Feb. 1683; d. La Bermondiere, Me., 17 Oct. 1757. He studied under the Jesuits at Poitiers, and afterward at Bourges, and went to Paris in 1703. His relative, the president, Hénault, introduced him to the savants of the metropolis, and in 1708 he was chosen a member of the Academy of Sciences, to which he had presented some memoirs on geometry. For nearly 50 years he continued to be one of its most active members, his labors embracing the arts, natural philosophy and natural history. He was appointed to assist in the 'Description des Divers Arts et Métiers,' published by the Academy, and in executing his part of the undertaking pointed out the way to various improvements by the application of the principles of physics and natural history. He made important observations on the formation of pearls and discovered that the "turquoises" of Languedoc consisted of the fossil teeth of extinct animals; but among his most useful researches must be reckoned those of which he gave an account in his 'Traité sur l'Art de Convertir le Fer en Acier, et d'Adoucir le Fer Fondu' (1722), in which he first made known in France the process of manufacturing steel. He received therefor a pension of 12,000 livres (about \$2,400). As a natural philosopher he is principally celebrated for the invention of an improved thermometer, which he made known in 1731. (See THERMOMETER). The fabrication of porcelain also occupied much of his attention, and led him to the discovery of a kind of enamel, called the porcelain of Réaumur, in

1739. His 'Mémoires pour Servir à l'Histoire des Insects' (1734-49) places him in the first rank of modern naturalists. In it he demonstrated, among various things, the correctness of Peyssonnel's assumption that corals are not plants, but animals. He bequeathed his priceless collections of minerals, plants and manuscripts to the Academy of Sciences.

REAVIS, James Bradly, American lawyer and jurist: b. Boone County, Mo., 1848. He entered Kentucky University, but did not complete the course, was admitted to the bar in Hannibal, Mo., in 1872, and for two years was editor of the *Monroe City Appeal*. In 1874 he removed to the West, and in 1880 settled in Washington Territory, where he established a law practice. He was a member of the upper house of the Territorial council in 1888 and a regent of the Territorial University, until Washington became a State. In 1889 he was an unsuccessful candidate for supreme judge, and from 1896 to 1902 was chief justice of the Washington Supreme Court.

REBAPTIZERS, those who taught that the repetition of baptism was under certain circumstances imperative. The term is specifically used of the Baptists who enforce rebaptism in the case of all who have not been baptized by immersion. Views with regard to rebaptism have been varied. Many early Christians declared it unnecessary even for one who had been baptized by an unbeliever or by a child in play. In doubtful cases the hypothetical or conditional form was enjoined, as in the Book of Common Prayer, and in accordance with the decretal of Alexander III (1159-81).

REBEC, or **REBECK**, a stringed musical instrument of the violin kind, said to have been introduced by the Moors into Spain. It soon became popular all over the Continent, being the favorite instrument of minstrels and of village musicians, and up till the end of the 17th century playing the same important part at fairs, rustic games and weddings as does the violin at the present day. It was somewhat larger than the latter instrument, but had only three strings, which were tuned in fifths, and rubbed with a bow. The earliest known representation of the instrument, however, taken by the Abbé Gerbert from a manuscript of the 9th century, gives it but one string. The neck of the rebec terminated in a more or less grotesque representation of a human head. Milton in his 'L'Allegro' alludes to the instrument as the "jocund rebec." The minstrels of the Middle Ages used four classes of rebecs, the treble, alto, tenor and bass.

REBECCA, a character in Scott's 'Ivanhoe,' daughter of the Jew, Isaac of York. She falls in love with Ivanhoe and nurses him after the tournament of Ashby, and he in turn saves her life by appearing as her champion in the lists after she has been convicted of sorcery and condemned to be burned at the stake. She leaves England with her father to live in Spain.

REBECCAITES, or **REBEKAH'S DAUGHTERS**, a singular association formed in South Wales, in 1839, for the destruction of turnpike-gates and tollhouses. The rioters were generally dressed in women's clothes, under a leader in the same guise, and made their attacks by night on horseback. The curious ap-

pellation by which they designated themselves was derived from the scriptural passage regarding Rebekah—"Let thy seed possess the gate of those who hate them." Successful for a time they were emboldened to greater lawlessness and were attacked and dispersed by the military.

REBEKAH LODGES. See **ODD FELLOW.**

REBEL YELL, the cry of the Confederate troops as they rushed to battle in the Civil War, although as a matter of fact they frequently shouted the names of their States, as "On Virginia!" "On North Carolina!"—and so forth. It is difficult to interpret the rebel yell in written language. It was very different from the full-toned "hurrah" of the North, being more like a shriek. Near the crisis of a charge the men would change from a double-quick to a mad rush, wildly yelling "Y-Yo Yo—Wo-Wo," for the triple purpose of encouraging each other and confusing and terrorizing the enemy.

REBELLION, an uprising with force and arms against established authority. A rebellion may be an armed outbreak for the purpose of obtaining the redress of a grievance or preventing the enforcement of an obnoxious law; Shays' Rebellion in Massachusetts having been an example of the former, and the Pennsylvania Whisky Insurrection of the latter. Rebellion of a more formidable character is that which attempts to establish a new and independent organization in place of the existing government. Such was the American Revolution and such also was the unsuccessful attempt to perpetuate the Southern Confederacy. Old World rebellions have been chiefly dynastic, at least up to the 19th century—that is, wars between reigning families and others, usually akin to them, which claimed the right to rule. The rebellion against Charles I of England was of a different character, being prompted by aspirations for civil liberty and religious reform. The expulsion of James II was of a similar motive and the American Revolution was a struggle for the inalienable rights of man.

In former ages and up to a very recent period conquered rebels were treated with great severity, being put to death, maimed or enslaved. In partly civilized countries such as China, rebels are treated now with the greatest cruelty. The more advanced nations, however, while retaining on their statute books the Draconic code of times gone by, treat beaten insurgents with leniency. After the downfall of the Southern Confederacy the only penalty inflicted was the disfranchisement for a time of the leaders of the rebellion, all being eventually admitted to the full rights of citizenship. British subjects who took sides with the Boers in the late South African War were, when convicted, imprisoned for short terms and disfranchised, although most of them probably escaped all punishment.

With the extension of suffrage came a consequent ability of the people to secure redress of wrongs without resort to violence. The causes which provoked rebellion in olden times are disappearing, while, apart from Carlist insurrections in Spain, there were no dynastic rebellions in Europe until after the opening of the World War in 1914, when the most notable ones were in Russia, where the Romanoff dynasty was displaced, Tsar Nicholas an-

nouncing the abdication of himself and his son, the immediate heir, 17 March 1917; and in Greece, where King Constantine abdicated 12 June 1917, on the demand of the protecting Powers, following a rebellion centring in Crete under the leadership of former Premier Venizelos.

REBELLION, War of. See **CIVIL WAR IN AMERICA.**

REBER, rä'bër, Franz von, German art-historian: b. Cham, Bavaria, 10 Nov. 1834. He studied in Munich, Berlin and Rome, became a lecturer at the University of Munich in 1858, was appointed professor at the Polytechnicum there in 1863 and in 1869 occupied the chair of history of art in that institution. In 1873 he became director of the Royal Gallery. He has translated Vitruvius' 'Architecture' (1865) and Rooses' 'History of the Antwerp School of Painting' (1880), and has written 'Geschichte der Baukunst im Altertum' (1864-67); 'Kunstgeschichte des Mittelalters' (1886); 'Geschichte der Malerei vom Anfang des 14. bis zum Ende des 18. Jahrhunderts' (1894); 'Die phrygischen Felsendenkmäler' (1897), etc.

REBER, rä-bär, Napoleon Henry, French composer: b. Muhlhausen, Alsace, 21 Oct. 1807; d. Paris, 24 Nov. 1880. After studying with Reicha and Le Sueur, he wrote chamber music of remarkable merit and in 1851 was appointed professor in the Conservatory, and succeeded Halévy in the chair of composition 1862. Among his works are 'Le Diable Amoureux' (1840), a ballet; 'Le Nuit de Noël' (1848); 'Le Père Gaillard' (1852); 'Les Papillotes de M. Benoist' (1853), and 'Les Dames Capitaines' (1857), all four comic operas. He also produced some instrumental work of a high order—four symphonies, one overture, one series for the orchestra, three stringed quartets, one stringed quintet, one pianoforte quartet, seven pianoforte trios and miscellaneous pieces. His 'Traité d'Harmonie' (1862) is a standard work.

REBISSO, Louis T., American sculptor: b. Italy, 1837; d. Norwood, near Cincinnati, Ohio, 3 May 1899. At 20 he joined in Mazzini's attempt to establish an Italian republic (see MAZZINI, G.), and was obliged to leave Italy. Taking refuge in the United States he settled in Boston, Mass., where he worked for several years in monumental yards. Subsequently he went to Cincinnati, Ohio, where his fame as an artist developed. He had studied in Italy with the sculptor Rubalto and in the Art Academy under Professor Varni, and in Cincinnati he worked with T. D. Jones. His leading works are the equestrian statues of General McPherson in Washington, D. C.; of General Grant in Lincoln Park, Chicago, and of Gen. W. H. Harrison in Cincinnati.

REBOUND CHECKS, devices attached to the running-gear of automobiles and designed to check the rapid reaction of a spring which has been suddenly compressed, and thus prevent the bouncing movement of a car, which is induced by the extreme resiliency of modern springs. This reaction causes a bouncing movement, which affects the steering, and by its lifting action tends temporarily to diminish the grip of the driving wheels on the road. It is also calculated to produce side-slip, sets up a

violent sway at corners and causes discomfort to passengers. Rebound checks are of varied types, one in very general favor consists of two arms, one attached to the frame and the other to the spring centre. These arms form an L-shaped link connected by a disc. The disc forms a friction-grip which tends to make the car spring drag when recovering, so that any violent reaction of the frame is absorbed by the check. Another variety, often seen on light cars, consists of a circular box attached to the frame and containing a wound-up spiral spring of great strength, the outer end of which is attached to the axle or spring clip. The action in both varieties is the same, a too-great reaction of the frame being prevented in both cases. Another method consists in introducing friction in the working of the springs. This is sometimes done by clipping together the leaves of the springs. Check-leaves are also introduced above the long spring leaf and help to retard the action of the latter when it shoots its load upward on the rebound. Another device, a cam-shaped piece with an arm, is set in a depression. When the arm is rotated—which only happens when the spring is suddenly compressed—the two rings are separated more and more from one another which action tends to squeeze together the parts of a minute clutch, one part of which is affixed to the frame and the other to the movable cam and arm-piece. See **SHOCK ABSORBERS**.

REBUS, a mode of expressing words or phrases by pictures of objects whose names bear a resemblance to those words, or to the syllables of which they are composed. Many of the ancient coats of arms were rebuses on the names of those who bore them; thus a lock and a heart for the name of Lockhart, an eye and a tun (a barrel) for that of Eyton, etc. Many family badges bore mottoes of similar import, as 'Ver non semper viret' of the Vernons. In heraldry, a rebus is a device intended to represent a proper name by a picture; a bearing or bearings on a coat of arms, containing an allusion to the name of the owner; as in the coat of the family of Arches, which consists of three arches, two simple and one double, borne on a shield; and that of the Dobell family, who bore on a sable shield a doe passant, between three bells argent. In the Middle Ages rebuses were very common among ecclesiastics and others who had no right to use armorial designs.

RECALL, The, or as it was formerly termed, the "imperative mandate," is a process by which the people, at their will, may vacate any office before the expiration of the term for which the person holding that office was elected. Should any public official fail properly to perform the functions of his office or be guilty of any act indicating that he is unworthy of the future confidence of the people, a reasonable minority of the voters may petition for his recall. The recall is not a new development but has been found in Greece and in the government of the early Germanic tribes, and in the United States has been known since Revolutionary times—Pennsylvania's delegates to the Continental Congress who refused to sign the Declaration of Independence having been "recalled" and others sent in their places. Article 5 of the Articles of Confederation gave to each State the power "to recall its delegates or any of them, at any time within the year, and to

send others in their stead for the remainder of the year." The chief difference between the old and modern methods is that under the former the representative assemblies recalled the officers whom they had elected while in modern times this power of removal rests with the individual voter in the ballot booth. Los Angeles was the first American city to adopt the recall, the amendment to its charter, passed in 1903, being modeled after the cantonal law of Schaffhausen, Switzerland. From Los Angeles the movement has spread to many of the western cities, particularly to those which have adopted the commission form of government. In 1907 Iowa applied the principle to cities of 25,000 or more population and in 1908, by a large majority, Oregon made every State official, including judges of every grade, "subject to recall by the legal voters of the state or of the electoral district from which he is elected." As applied to public officers, the Oregon law is typical, though later laws differ in minor details. In Oregon the recall petitions must bear the signatures of 25 per cent of the number of electors who voted at the preceding election in the district of the person whose recall is demanded. Should the official refuse to resign within five days after the petition is filed, his name, as well as that of any other candidate nominated, is placed upon the ballot for a special election, to be held within 20 days. This ballot contains a paragraph of not more than 200 words setting forth the reasons why recall is demanded, and a similar space is allowed the official to plead his case. If the official fails to obtain a majority of the votes cast, the successful candidate serves the unexpired term; the discredited official is deemed removed when the successful candidate has qualified for the office. But the Oregon statute contains a prohibition against the circulation of a petition to remove a State official unless he has been in office for six months, while members of the legislature may be recalled after the lapse of five days from the opening of the legislative session following their election. If a recall be unsuccessful, any further petition must be accompanied by sufficient money to cover the cost of a new election, this sum to be raised by the petitioners. Boston employs a limited power of recall. The mayor's term of office is four years but at the State election one month prior to the expiration of the mayor's second year in office the ballot must contain the question: "Shall there be an election of mayor at the next municipal election?" If the vote be in the affirmative any number of candidates may run against the mayor at the ensuing election. A general average of the laws would place the percentage of petitioners at about 25. California requiring 12 per cent for State officers, with special restrictions, while 15 per cent is necessary under the commission government laws of South Dakota and under the special charters of Oakland, Modesto, Vallejo and Santa Cruz, Cal.; 20 per cent under the commission government laws of Washington and the special charters of Grand Junction, Col., Mankato, Minn., Pontiac, Mich., Fort Worth and Denison, Tex., Parkersburg, W. Va., Stockton, Cal., Wyandotte, Mich. and Lowell, Mass.; 25 per cent under commission government laws of Montana, Wyoming, New Jersey, Kansas and the special charters of San Luis Obispo, Eureka,

Bartlesville and McAlester, Cal., Sapulpa, Okla., Austin, Tex., Lawrence and Haverhill, Mass. and Gardiner, Me.; 30 per cent under commission government laws of Nebraska and under charters of Ardmore and Enid, Okla., and Colorado Springs, Col.; 33 per cent under the commission government law of Louisiana; 33½ per cent under the commission government law of Wisconsin and the special charter of Corpus Christi, Tex.; 35 per cent under commission government law of Idaho and in Dallas, Tex., Oklahoma City and Tulsa, Okla. and Wilmington, N. C.; 40 per cent under the special charters of Holdenville, Okla. and Knoxville, Tenn.; and 55 per cent under the commission government law of Illinois.

In South Dakota the recall may be invoked against city officials, and this process of removal has been adopted in some cities of Massachusetts, New Jersey, Florida, Alabama, Louisiana, Kansas, Nebraska, North Dakota, Wisconsin, Wyoming, Idaho, Nevada, Washington, etc. Sweeping recall amendments have been adopted in California (1911), Nevada and Colorado (1912, the law of the latter State applying to judicial decisions also), and in 1912 Arizona struck from the recall provision in its 1911 constitution the clause which excepted elective judicial officers from the operation of the recall. In 1912 Idaho and Washington, in 1913 Michigan and in 1914 Louisiana adopted amendments which made the recall operative against all State officials except the judiciary. In 1914 Kansas adopted a law which applies to appointive as well as to elective officers. In 1912 the Arizona legislature adopted a measure the intent of which was to apply the recall to United States senators, representatives and judges, but since these officials hold office under the Federal Constitution they are not directly amenable to recall in a State election. As regards a Federal judge the people may advise his resignation and suggest to the President a person they deem fitted for the position, but the question of action on the advice given depends entirely upon the judge and the President. Respecting senators and representatives, however, the advisory recall is of great moment; the candidates, who are nominated in direct primaries, are afforded the option of pledging or refusing to pledge themselves to obey an advisory vote of recall and few care to incur public opposition by withholding the pledge.

The recall of judicial decisions was proposed by Mr. Roosevelt in 1912, his idea being that the people should have the right not only to recall a decision itself but to ratify or disapprove the constitutional principle upon which the decision was based. On 21 Feb. 1912, when addressing the Ohio constitutional convention, he said: "If any considerable number of people feel that a decision is in defiance of justice, they should be given the right by petition to bring before the voters at some subsequent election, special or otherwise, as might be decided, and after the fullest opportunity for deliberation and debate, the question whether or not the judges' interpretation of the constitution is to be sustained." In 1912 the people of Colorado initiated and adopted an amendment to the State constitution providing for the recall of judicial decisions, the use of the referendum being granted to the people for the purpose of

ordering the enforcement of a statute which, after passage by the legislature and approval by the governor, has been vetoed by the State Supreme Court. See INITIATIVE; REFERENDUM.

A., 'Political Parties and Party Problems' (rev. ed., New York 1914). In *The National Municipal Review* (Vol. III, pp. 693-701, October 1914) is a summary by Charles F. Taylor of the uses of the initiative, referendum and recall in various cities up to 1914.

RÉCAMIER, ră-kā-mě-ā, Jeanne François Julie Adelaide Bernard, French social leader: b. Lyons, 4 Dec. 1777; d. Paris, 11 May 1849. She was educated at the convent of La Deserte. At 16 she went to Paris, whither her father, a wealthy banker, had transferred his business. Her extraordinary beauty and talents brought round her shoals of suitors belonging to the world of letters, finance and politics, and in 1793 she was married to Jacques Récamier, a rich banker, more than double her own age. The Récamier salon was long filled with many of the celebrities of the day. Though she wrote nothing, she, by her confidential intercourse with Chateaubriand and others, exercised no slight influence on French literature. Under the empire she was opposed to Napoleon, as he had placed her father under surveillance for his royalist tendencies, and Napoleon took his revenge by refusing to support the bank of her husband during a crisis. It accordingly failed, and Madame Récamier was obliged to quit Paris. She took up her residence with her friend Madame de Staël at Coppet, and afterward traveled, like her, until the downfall of Napoleon, when she again opened her salon in the Abbaye-aux-Bois at Paris. Consult 'Souvenirs et Correspondance tirés des Papiers de Madame Récamier' (1859, 4th ed., 1873) and 'Madame Récamier' (1872), both edited by her niece, Madame Lenormant; also the biography by Brunier (1875).

RECAPITULATION, or BIOGENETIC LAW, in *zoology*, terms applied to the parallel which exists between the embryonic development of an individual animal (ontogeny) and the historical evolution of its race (phylogeny). This parallel is explained by the theory of evolution (q.v.), according to which, in the words of Sidgwick, "the developmental history of the individual appears to be a short and simplified repetition, or in a certain sense a recapitulation, of the course of development of the species." This class of facts was recognized more or less completely by the earliest naturalists, and was extensively studied and formulated by Von Baer and Agassiz previous to the explanation of them by means of the doctrine of descent; but it should be added that obscurities still exist, concerning the explanation of which embryologists are in doubt or at variance. Examples may be found in the embryological development of all vertebrates. Thus the frog develops through stages in which the embryo just before hatching is very fish-like, after hatching becomes a tadpole which exhibits many newt-like characters; and finally reaches the permanent frog stage. This accords with the comparative rank of the fish, newt and frog groups in classification; and also with the succession appearance of these groups. Man, as the highest animal, exhibits most completely these phenomena. In the earliest stages the human embryo is indistinguishable from that of any other creature. A little later the cephalic region shows gill-slits, like those which in a shark are a permanent feature, and the heart is two-chambered or fish-like. Further development closes the gill-slits, and the heart changes to the reptilian type. Here the reptiles stop, while birds and mammals advance further; but the human embryo in its progress to the higher type recapitulates and leaves features characteristic of lower mammalian forms — for instance, a distinct and comparatively long tail exists. Most of these changes are completed before the embryo is six weeks old, but some traces of primitive and obsolete structures persist throughout life as "vestiges" or "rudimentary organs," and others appear after birth in infancy, as the well-known tendency of babies to turn their feet sideways and inward, and to use their toes and feet as grasping organs, after the manner of monkeys. This recapitulation of ancestral characters in ontogeny is not complete, however, for not all the stages are reproduced in every case, so far as can be perceived; and it is irregular and complicated in various ways among others by the inheritance of acquired characters. The most special students of it, as Haeckel, Fritz Müller, Hyatt, Balfour, etc., distinguish two sorts of recapitulation "palinogenesis," exemplified in amphibian larvæ and "cœnogenesis," the last manifested most completely in the metamorphoses of insects. Palinogenesis is recapitulation without any fundamental changes due to the later modification of the primitive method of development, while in cœnogenesis, the mode of development has suffered alterations which obscure the original process of recapitulation, or support it entirely. See EMBRYOLOGY, and consult authorities mentioned thereunder.

RECAPITULATION IN PLANTS. See PLANTS, RECAPITULATION IN.

RECEIPT, in *law*, a written document, declaring that certain goods or a sum of money have been received. When made out in full, a receipt should contain (1) the date when the merchandise or money was received, (2) the name of the person or firm from whom received, (3) the name of the person who received it and (4) for what the money is paid or deposited. A receipt may be in full or in part payment of an account, and operates accordingly. A receipt, though evidence of payment, is not absolute proof, and this evidence may be rebutted by proving that it was given under misapprehension. A receipt made by an authorized agent is as good as one made by the principal. A joint trustee who signs a receipt for money, only because the receipt without his signature would have no effect, may, unless he is himself in default, show that he did not receive the money, and can thus remove or limit his liability; but a co-executor who is not under the necessity of signing a receipt to give it effect, is bound by the receipt that he signs.

RECEIVER, in *law*, is an officer of the court through whom the court, on account of its jurisdiction, takes possession of property which is the subject of a suit, for the purpose of preserving it from injury or loss, secures the proceeds and finally disposes of them according to the rights of all parties interested. Receivership is a remedial agency for the purpose of preserving the property in question from waste, destruction or deterioration pending litigation; it is auxiliary to the main action. It is a remedy which originated in the English Court of Chancery and is purely equitable. Under the existing English law, and also that in Canada, a receiver may be appointed when the court deems it just or convenient. In the United States, courts of equity have general authority to appoint receivers, and in most States by statutory provision. The courts are generally disinclined to appoint a receiver, except that from all the circumstances it appears essential for the purpose of the preservation of the property in controversy. Technical injuries and circumstances which are doubtful are insufficient. A receiver will be appointed to prevent a fraudulent transfer, or possession of property, or for the protection of estates, or of property of a partnership where dissolution is desired and the partners cannot agree; of mortgaged property, foreclosure proceedings, corporations which are insolvent, or which are fraudulently managed. The appointment of a receiver rests entirely within the discretion of the court to which the application is made, and the court also has discretion as to its choice of receiver. One will not be appointed a receiver who is not qualified to perform his duties, and he must be impartial, independent and disinterested. A corporation may be appointed a receiver if authorized by its charter. In order to obtain a receiver one must show the right to the property, or a lien upon it, or that the property in question was obtained by fraud, or is in danger of loss from waste, or the misconduct or insolvency of the party in possession, and the circumstances must show extreme necessity. A receiver is created by the court whose officer he is and is under its control, supervision and protection. His duty is purely ministerial and the utmost good faith is required of him; his acts should be with the

general or special authority of the court and must be without discrimination for the interests involved. A receiver may employ counsel, agents and assistants, make necessary repairs, pay taxes and bring suits. He must keep the property insured and is required to give a bond for faithful performance of his duty. He takes complete possession of the property at the time when appointed; his liability is generally official, and he is responsible to any person who sustains loss through his negligence or misconduct in relation to his trust; he is entitled to a compensation for his services, which is in some jurisdictions fixed by statute, in others by the discretion of the court. Consult Alderson, W. A., 'Practical Treatise on the Law of Receivers' (New York 1905); High, J. L., 'Treatise on the Law of Receivers' (4th ed., Chicago 1910); Kerr, 'Law and Practice as to Receivers' (6th ed., Toronto 1912); Smith, J. W., 'The Law of Receivership' (Chicago 1897).

RECEIVING STOLEN GOODS, *in law*, the taking possession, with felonious intent, of goods known to have been stolen. Positive knowledge of the theft is not required to prove guilt if the circumstances are such that ordinary powers of observation would detect theft. The fact that one receiving the stolen goods may not intend to profit by it does not change the character of the offense, the act of aiding the thief being criminal. An intention to hold for a reward also comes under the classification of fraudulent intent. The offense is a felony or a misdemeanor, according to the value of the goods received and is either classed with larceny or punished with similar severity.

RECENT PERIOD. That division of the geological time-scale including the most recent portion of geological history. It is usually thought of as beginning with the appearance of man on the globe and running down to the present, and is, therefore, sometimes called the Human Epoch. It follows immediately upon the Pleistocene Period (q.v.) and is treated as a subdivision of this by some geologists, while others group Pleistocene and Recent under the Quaternary Period (q.v.). See GEOLOGY.

RECHABITES, rēk'a-bīts, members of a kind of religious order in ancient Israel whose rule was in some respects like that of the Nazir or Nazarites. Like them they were bound by vow to abstain from the use of wine. In their contempt for luxuries and the ways of settled life, they chose to live in tents rather than houses, and refused to sow grain or plant vineyards; their ideal was the nomad patriarchal life amid their flocks (35 Jer., 2-19). The order had its origin in the northern kingdom of Israel and was founded by Jonadab or Jehonadab, son of Rechab (whence the name Rechabites), in the reign of Jehu, king of Israel (2 Kings, x). After the fall of the kingdom of the North a body of the Rechabites entered the kingdom of Judah and continued to live apart from cities and towns till the approach of Nebuchadnezzar they took refuge in Jerusalem. Independent Order of Rechabites is the style of a total-abstinence beneficial society founded in England 1835 and of which a branch was instituted in the United States 1842. In 1916 the order had 701,040 members in the United States and Great Britain, organized in four grand and 4,037 subordinate tents.

RECIDIVISTS, *in law*, offenders who relapse into former criminality. Statistics show that a large percentage of persons convicted of crime are old offenders, or recidivists. Figures differ in various countries and in various parts of the same country as to the percentage. Perhaps at least 40 per cent is the average, but in some countries as high as 70 per cent has been reported. It is quite probable that more than half the serious crimes committed to-day in the United States and in other civilized countries as well are committed by recidivists, who have adopted crime as a profession. Modern penal systems have proved unable to cope with the evil by present-day methods, and it is admitted that a change is imperative. Indefinite terms of imprisonment have been suggested and are being adopted in many countries to meet the condition. In the United Kingdom, by the Prevention of Crime Act of 1908, the courts have been empowered to add a further period of from 5 to 10 years on habitual criminals in addition to a sentence of penal servitude.

In the United States the indefinite term has been accepted also as one method to combat the evil of recidivism, and the general tendency in some States is in this direction. However, in other States there seems to be a strong sentiment growing in favor of supplying industrial training for criminals while in prison and securing employment for them on their discharge. In addition to these methods, segregation of defectives, who make up a considerable part of the inmates of prisons, and organized care of penniless children, whether orphaned or deserted, from among whose ranks many criminals are later developed, are advocated and are being put into effect. This is attacking the problem at its source, and its general adoption would, it is believed, lead to a great decrease in crime. See PENOLOGY.

RECIFE, Brazil. See PERNAMBUCO.

RECIPROCAL, *in grammar*, reflexive. Applied to verbs which have as an object a pronoun standing for the subject; as, "Bethink yourself." It is also applied to pronouns of this class; as a noun, that which is reciprocal to another thing. Specifically, in mathematics, the quotient resulting from the division of unity by the quantity. The reciprocal of a vulgar fraction is the denominator divided by the numerator.

RECIPROCITY. See UNITED STATES, RECIPROCITY.

RECITATIVE, rēs'i-tā-tēv' (Italian, *recitativo*), a species of musical recitation, forming the medium between song and rhetorical declamation, and in which the composer and performer, rejecting the rigorous rules of time, endeavor to imitate the inflections, accents and emphasis of natural speech. Although the rules of time and rhythm are not strictly observed, recitative is written generally in common time, in order to facilitate the reading. In its approach to speech, therefore, recitative is mostly syllabic song, that is, each syllable has generally but one tone, and the tones themselves are less prolonged than in song strictly so called. Hence recitative has not a distinct, developed melody and a regular modulation; it may, according to the meaning of the words, pass with comparative freedom through the various tones. On the other hand, the tones

of recitative are generally musical tones, of distinct height or depth generally, because in *recitativo parlante*, in the *opera buffa*, the tones become closely allied to those of speech. When recitative approaches still more to strict song, in respect to time and melody, the *arioso* originates. In short recitative may be called *declamation in musical tones*. Recitative includes the simple (by some also called the *parlante*) and the accompanied, or more properly, the *obbligato*. In simple recitative accompaniment also takes place, but it consists only in simple chords, which are given continuously, or interruptedly. In the *obbligato* recitative the instrumental accompaniment is of more importance, and consists of either sustained chords by the greater portion of the orchestral instruments, or even of florid passages. In the recitative much is left to the singer in respect to time, rhythm and melody, which require much musical judgment and knowledge of harmony, in order to agree with the *obbligato* accompaniment. Recitative was used largely in the ancient drama, and is frequent in the modern opera to express some action or passion, to relate a story, reveal a secret or design, etc. Giulio Caccini (abt. 1546-1615), called by Angelo Grillo "the father of a new style of music," Emilio del Cavalieri (abt. 1550-99), and Claudio Monteverde (1567-1643) are each credited with having introduced the recitative in Rome. See OPERA.

RECKE, rĕk'ĕ, Ernst von der, Danish poet: b. Copenhagen, 14 Aug. 1848. His first work was a lyrical drama, 'Bertram of Born' (1873), performed with great success at the Theatre Royal at Copenhagen. Following this came 'King Liuvigild and his Sons' (1878), a tragedy; a dramatic poem 'Archilochus' (1878); 'Knud and Magnus' (1881), a tragedy; 'Fru Jeanna' (1891), a tragic opera; and the 'Duchess of Burgundy' (1891). Between 1876 and 1890 he published several collections of lyrics and in 1881 a great work representing six years of labor in a field in which he is a recognized master, 'Principles of Danish Versification as Manifested in Its Historic and Systematic Development.' Besides writing books for children he has published translations of Bornier's 'La Fille de Roland' (1876) and Rostrand's 'Les Romanesques' (1896).

RECKLINGHAUSEN, rĕk'ling-how-zĕn, Prussia, in the province of Westphalia, 15 miles northwest of Dortmund, 31 miles southwest of Münster. It has good Catholic and Protestant schools. Its manufactures include damasks, wicks, tobacco, cabinet wares and bricks. There are coal mines in the vicinity. Pop. about 35,000.

RECLAMATION LAWS. Under this heading are treated two groups of statutes known respectively as the Carey Act and the Reclamation Law.

The Carey Act provides for the grant of 1,000,000 acres of desert land in each of the States in which desert land occurs upon condition that the State will secure the reclamation of these lands whereupon patent will issue to the State or its assigns. Recent legislation has increased the grant to 2,000,000 acres each for Idaho and Wyoming.

The usual plan is for the State or Territory to make a contract with a corporation by

which the latter is to build the works and may make certain charges for the water rights, the State selling the lands at a price which is usually nominal.

A comparatively small amount of land has been reclaimed under the Carey Act. Of the 14 States that could have taken advantage of this act nine have requested segregations with a view to reclamation, amounting to about 3,700,000 acres. The total area which has been patented upon proof of reclamation up to 30 June 1915 is 601,573.38 acres.

It is evident, therefore, that the Carey Act did not meet some of the more difficult conditions of reclamation in the large area of arid lands that might be reclaimed, variously estimated at from 20 to 50 million acres.

As early as 20 March 1888 Congress had authorized a thorough study of the water supply of the Western States where irrigation is needed, and on 2 October of that year had made an appropriation for the selection of reservoir sites which when designated by the director of the geological survey were to be held reserved until further action of Congress. The following year another appropriation was made for continuing the work. After that no further appropriation was made for a number of years. The reservoir sites which had been reserved, numbering several hundred, were still to some extent available for use and some of them have been used by the government. A number have been taken by private parties under a general permissive act of 26 Feb. 1897.

On 17 June 1902 Congress went a step further toward completing the policy initiated by the irrigation survey of 1888 and 1890 and appropriated the proceeds from the sales of public lands in the arid and semi-arid States for the construction of irrigation works. Under this act the Reclamation Service was organized and has constructed a large number of irrigation systems. The cost of construction is repaid by the water users and these repayments, together with the annual receipts from the sales of public lands, constitute a revolving fund to be used indefinitely in continuing this work. The Reclamation Service has now under irrigation more than 1,500,000 acres of land. The completed systems which have heretofore been constructed and are partially in use will provide for the irrigation of about 3,000,000 acres, and under the plan of re-expending the amount returned for the cost of the work this area may be ultimately much increased.

For a detailed statement of the work under the Reclamation Act see UNITED STATES RECLAMATION SERVICE.

RÉCLUS, rĕ-klŭ, Jacques Elisée, French geographer: b. Sainte-Foy-la-Grande, in the Gironde, 15 March 1830; d. Brussels, Holland, 4 July 1905. After being educated in the college of his native town and at the University of Berlin he traveled in Germany, England, Ireland and America. In 1859 he began to contribute to the 'Revue des Deux Mondes' articles on geography, geology, literature, politics, social economy and other subjects, and also became associated with several geographical journals. During the siege of Paris and the Commune he was a member of the National Guard. Captured early in 1871 he was condemned to deportation, but his sentence was

commuted to exile and he spent some years in Italy and Switzerland. In 1883 the Tribunal at Lyons passed sentence upon him and Prince Kropotkin as being anarchist leaders associated with the International Workingmen's Association, but Reclus escaped punishment by his absence from the country. In 1892 he was appointed professor of comparative geography in the free university of Brussels. His greatest work is his *'Nouvelle Géographie Universelle: La Terre et les Hommes'* (1875-94), a splendid monument of the best geographical learning of our time. There is an English translation by Ravenstein and Keane (1887 onward). His other works include *'La Terre: Description des Phénomènes de la Vie du Globe'* (1867-68), translated into English as *'The Earth'* (1871); *'Histoire d'un Ruisseau'* (1869); *'Nice, Cannes, Antibes, Monaco, Menton, San Remo'* (1870); *'Les Phénomènes Terrestres: Les Mers et les Météores'* (1873); *'Histoire d'une Montagne'* (1880), translated as *'The History of a Mountain'* (1881); and *'L'Évolution, la Révolution et l'Idéal Anarchique'* (1898), treating of his social philosophy. His publications relating to the United States include *'Le Mississippi, études et souvenirs'* (1839); *'Le delta du Mississippi et la Nouvelle Orléans'* (1859); *'De l'esclavage aux États-Unis, le code noir et les esclaves'* (1860); *'Les planteurs de la Louisiane et les abolitionnistes'* (1861); *'Le Marmorisisme et les États-Unis'* (1861); *'Le caton et la crise Américaine'* (1862); *'Les livres sur la crise Américaine: guerre de la sécession'* (1862); *'Les Noirs Américains depuis la guerre civile aux États-Unis'* (1863); *'Histoire de la guerre civile aux États-Unis'* (1864); and *'La commission sanitaire de la guerre aux États-Unis, 1861-1864'* (1864).

RECOGNITION MARKS. See **COLORATION, PROTECTIVE.**

RECOGNIZANCE, or RECOGNISANCE, in law, an obligation of record, which a man enters into before some court of record or magistrate duly authorized, with condition to do some particular act; as, to keep the peace, to pay a debt or the like. If the condition is not performed, the party bound by the bond forfeits his recognizance, as, in the case of a debt, the amount specified becomes immediately due.

RECOLLECTIONS OF CHILDHOOD AND YOUTH. Renan's *'Recollections of Childhood and Youth'* (*'Souvenirs d'Enfance et de Jeunesse'*) were written between 52 and 60, as the matured Orientalist and philosophic interpreter of religious evolution looked back with Celtic sensitiveness of poetic fancy on his own impressionable and strangely-ordered youth and the struggles of his adolescent manhood for intellectual emancipation. It is one of the world's rarest books of psychic interpretation and, except perhaps his *'Life of Jesus,'* the work for which Renan is most widely known. It tells of his childhood at Tréguier in Brittany, subtly bringing out the divided inheritance from a father of old republican seafaring folk, and a mother, half Gascon, half Breton, of the royalist trading middle class, intense in the sincerity of her simple, exceedingly narrow devotion. The resultant psychic complexity can be traced, with his words as guide,

through his whole after career. There are pleasant pictures of the seminary at Tréguier, with warm appreciation of the virtues of the Breton clergy and fascinating digressions on Breton piety. Then the *'Recollections'* tell how, not yet 16, he was suddenly summoned to Dupanloup's just reorganized seminary, Saint Nicholas du Chardonnet at Paris, "morally fixed, but as ignorant as one could be, with everything to discover." How his mind unfolded here and later at the Sulpician houses at Issy and in Paris is told with kindly discriminating account of his teachers and their ways. Gradually his philosophical and then his Hebrew studies brought about a struggle between vocation and conviction, the more intimate details of which were first revealed after his death in the correspondence with his sister Henriette, a very remarkable woman and the strongest personal influence in his life. With his breaking away from Saint Sulpice in 1845, a brief experiment at teaching in an Oratorian college, and his final self-emancipation, the *'Recollections'* end. This simple story of a young man's struggle to be true to his higher self is told with a frank directness, a subtlety of psychic perception, a sympathy for all noble feeling and honest conviction that give the book singular charm. An abridgment of the *'Recollections'* has been edited for schools (Boston 1902).

BENJAMIN W. WELLS,

Author of 'Modern French Literature.'

RECOLLET, rēk'ō-lēt, or RECOLLECT, the name given to certain reformed bodies of the Franciscan and other orders in the Roman Catholic Church. Among orders of men, an offshoot of the Augustinian hermits, which, under Louis de Montoya, obtained considerable popularity in Spain, was called by this name, and the order still exists at Medina-Sidonia, Leon and Pamplona; but outside of Spain the order is better known under the title of Reformed Franciscans, who were established in France under Henry IV and Louis XIV, and spread thence into Belgium and Germany. In France, before the Revolution, this order had 168 houses, forming seven provinces, under the direction of the general of the Cordeliers. It is also known as the Friars Minor of the Strict Observance of Saint Francis. In Spain an offshoot of the Cistercian order of nuns was also called by the same name. See also **ORDERS, RELIGIOUS.**

RECONCENTRADOS, rē-kōn-sēn-trā'dō, a Spanish term applied to the inhabitants of the rural districts of Cuba forced by the Spaniards, during the final war for liberty, to go to retention camps. Governor-General Weyler issued a decree that all of the peasant class not actively engaged in the insurrection but at their homes or ranches should be "concentrated" in or near certain towns. Disobedience to this decree incurred the penalty of death. General Weyler's purpose was to desolate the island in certain parts so that the insurgents could not get aid and food. With this end in view, the abandoned homes were frequently destroyed and whatever remained of value to the Spaniards was confiscated. Whole districts in the most productive part of the island were thus laid waste. Sugar mills were burned and other industrial property destroyed. Nearly 400,000

"reconcentrados" were forced within the Spanish lines. General Blanco permitted the "reconcentrados" to return to their homes.

RECONNAISSANCE, *rē-kōn'ā-sāns*, the examination of a territory, district, etc., or of an enemy's position, for the purpose of directing military operations. Also the preliminary examination of a country or district in reference to its general natural character, preparatory to a more particular survey for the purposes of triangulation or the construction of public works, as of a road, canal, railway, etc. The development of the aeroplane has entirely altered the character of reconnaissance in war. Formerly the cavalry were relied upon to make quick dashes into an enemy's territory and discover the nature of the roads, the high points, woods, streams, etc., and all they could learn of the enemy's strength and disposition of his force. But since the formation of aero squadrons, they have taken over nearly all this work wherever they exist, as they obviously can perform it to much better advantage. But for minor operations and for irregular warfare where aeroplanes are not available the old methods of observation obtain. Small bodies of independent cavalry are best, but where roads permit, automobiles and motorcycles are sometimes employed; or sometimes the duty will fall upon the infantry. In fact, a certain amount of reconnaissance must fall upon the infantry under any system, for the commander of forces in the field must keep himself informed as to his surroundings and guard against surprise attacks. It is common to send out small bodies of men at night to wander over the area between opposed armies and learn all they can of what is going on. A reconnaissance in force is the advance of a considerable body of troops with the idea of being able to fight effectively if attacked, or perhaps to form the vanguard of an attack. Reconnaissance is always closely allied with signaling (*q.v.*). See also **AERONAUTICS**, **HISTORY OF**, and various military titles.

RECONSTRUCTION. See **UNITED STATES**, **RECONSTRUCTION**.

RECORD includes anything which is set down in writing for the purpose of preserving memory and may be of a public or private nature. A record in a lawsuit is a complete written history of it from its beginning to its determination made by an officer duly authorized. In general, the rule is well settled that the pleadings which make up the record do not enter into details of the evidence, but merely set forth the conclusions or inferences, leaving the details of evidence to be supplied at the trial before a jury, or, if there is no jury, at the hearing before the judge or court. A trial by record means that one of the parties has set up some former decision of the court, while the other denies that such a decision ever existed; whereupon the only mode of solving the question is by producing the record of the former action. All books and memorials kept by public officers in accordance with the law, or which are connected with the proper discharge of their duty, are regarded as public records, as are also copies of papers which statutes require to be filed in public places. Generally anyone has a right to inspect public records and in many jurisdictions the removal of public records is regulated by statute, some of which hold

that to destroy, or remove, or injure the records is a criminal offense.

RECORDE, *rēk'ord*, Robert, English mathematician: b. Tenby, Pembroke, about 1510; d. London, 1558. He studied at Oxford, was elected to a fellowship of All Souls' in 1531, studied, and probably taught, mathematics and medicine at Cambridge, and later was instructor in a variety of subjects at Oxford. Having gone to London, he became, it is said, physician to Edward VI and Queen Mary. In 1551 he was made general surveyor of the mines and money; but despite this post seems to have been imprisoned for debt in King's Bench prison, where he certainly died. Among his works were 'The Grounde of Artes' (1540-1699), a work on "teaching the worke and practise of Arithmetike"; 'The Urinal of Physick' (1547), a comprehensive treatise on medicine; 'The Pathway to Knowledge, or First Principles of Geometry' (1551-1602); 'The Whetstone of Witte, or the Second Part of Arithmetike' (1557), the former a treatise on geometry, the latter on algebra; 'The Castle of Knowledge, a Treatise on Astronomy and the Sphere' (1551). For over a century his mathematical works were used as textbooks in the schools of England. He was the first to use the sign = for equality and to discover the method of extracting the root of multinomial algebraic expression. Besides his mathematical pre-eminence, Recorde was considered to be a skilful physician, an able lawyer and an accomplished philologist.

RECORDER, a title of ancient English derivation, the recorder in England being a person associated with the mayor and other magistrates of any city or borough, having jurisdiction in a court of record, for their better direction in matters of justice and proceedings according to law. The title is also given in some American States to an official having charge of real estate and other records and in New York it is applied to one of the criminal judges.

RECORDER, an obsolete musical instrument, formerly popular, resembling a flageole in shape, with a mouth-piece like a bird's beak. The instrument was wider in the lower half than in the upper; its tones were soft and pleasing and an octave higher than the flute. Milton speaks in his 'Paradise Lost' of

The Dorian mood of flutes and soft recorders:

it is also mentioned by Shakespeare in 'Hamlet' and Bacon, in his 'Natural History' say "The figures of recorders, and flutes, and fife are straight; but the recorder hath a less bore. The instrument was also used to teach birds to sing.

RECORDING OF CONVEYANCE OR DEEDS, the official and public registration in all States of all conveyances of land made at full length, either in the office of the clerk of the county where the land is situated or in what is known as the register's office. The statutes requiring these records are known as Recording Acts, and their purpose is to advise subsequent purchasers or encumbrancers of the property, of the existence of the prior deed of conveyances and of their contents; the due recording of a conveyance is by the "acts" made constructive notice to all subse-

quent purchasers or encumbrancers; and unless a conveyance is so duly recorded it is void as against a subsequent purchaser or encumbrancer in good faith who has no notice of the existence of such conveyance and whose deed is first duly recorded. In some States an unrecorded deed is fraudulent and void as against all creditors of the grantor and as against subsequent purchasers or encumbrancers for value without notice, even though their deeds be not recorded; but it is generally valid as against the grantor, his heirs and devisees, or against all persons having actual notice of it; in only one of the States is an unrecorded deed void as between the parties. Recorded deeds, other things being equal, take priority according to the time of record; and a deed is deemed recorded in most of the States from the time it is filed for record, i.e., from the time the minute is made on the deed, index, or entry-book by the register or county clerk. This minute consists of the day, the hour and the minute of filing. Records of all deeds must be entered alphabetically in two indexes, one under the grantors' names, the other under the grantees' names; separate indexes and record books are kept for conveyances and mortgages. Commonly after record, the deed is delivered to the person entitled to it. In nearly all the States, in order that a deed may be recorded, a certificate of acknowledgment, before a proper officer, of its due execution is necessary, or else its execution must be proved by an attesting witness and the proof must be properly certified by a proper officer; in addition to this, a seal of the grantor is generally necessary. Generally all deeds of real estate, mortgages, contracts relating to and affecting real estate, may be recorded. A duly recorded conveyance or instrument or a certified copy thereof may be read in evidence without further proof. If the land is situated in several counties, the deed or a certified copy thereof ought to be recorded in each of the counties. The Recording Act or statute usually prescribes the manner of recording. In England the grantee receives from the grantor all the deeds affecting the property, the so-called muniments of title. This is due to the fact that conveyances are not generally recorded in that country, while such a practice is unnecessary in the United States, where the title is shown by the public record and the deed of conveyance is the only document delivered to the buyer. See **TOWN'S LAND SYSTEM**.

RECREATION CENTRES. It is only in recent years that serious consideration has been given to the subject of recreation as a fixed phase of municipal life. The awakening of civic spirit, however, has shown that in order to receive the best from its citizens, the city is under obligation to endow them with both brain and brawn. As an economic and political entity, the strong, clean-minded and healthy person is the solution of many of the abusive shortcomings of city life, and to secure such, the idea of public recreation centres has taken firm hold. At first, the centre was a development of the gymnasium of the public schools, or of a place where young children might find amusements. But the idea has grown, so that to-day facilities are offered for persons of all ages or tastes.

In the United States, recreation has taken a

firm hold. The parks of the upper part of the City of New York have been laid out with the idea of giving recreation facilities to the public. Central Park, with its tennis court, zoological park, art and natural history museums, mall and public concerts, rowing and skating, is the great city playground for those unable to go to the country. The athlete, golf player, tennis player and others interested in outdoor sports and civic meets finds every facility in Van Cortlandt Park, while Bronx Park, with its zoological and botanical attractions, is the resort of thousands.

For purely athletic purposes, however, there recently has been planned and instituted a series of parks throughout the older downtown sections of the city, particularly in the tenement districts. The region known as "Five Points"—once the centre of poverty and crime—has been opened up, and a large recreation centre established in the centre of the Italian colony, known now as Mulberry Bend Park. Hamilton Fish Park is another that has been created among the tenements, while De Witt Clinton Park is noted for its "farm school," showing children the possibilities of rural life. The most interesting, perhaps, is Battery Park, at the extreme southern point of Manhattan Island, a place of interest to every visitor in the city for its notable aquarium, the immigrant landing, the view of the harbor and its shipping, and its nearby trip to the Statue of Liberty. Numerous steamboats leave from Battery Park to the many bathing and resort beaches, picnic grounds and recreation centres, such as Coney Island.

Perhaps the greatest advances in the subject of recreation have been made in Chicago, a city that a generation ago ranked very low in per capita park space. Being of a level contour in general, there were but few points that offered special park features. Recently, with the quickening of civic spirit, the city government has taken steps to improve and extend its park system, particularly with the idea of serving the public in its recreations, and to-day Chicago has not less than 60 playgrounds, which, together with the parks, cover an area of about 35,000 acres. Of chief interest, however, is the fact that recreation centres in Chicago have been developed on a plan which, for completeness, ranks with the best. The neighborhood park is a reality, a civic centre where persons of all ages may find recreation. Ball grounds, golf courses, tennis grounds, bathing beaches, swimming pools, bath houses, sand piles, lakes, reading rooms—most frequently in connection with branches of the Public Library—halls for public meetings, debate, and neighborhood theatricals, restaurants and lunch rooms, and even savings banks, are to be found in these parks. Grant Park, on the Lake Shore contiguous to the "Loop," or business district, is one of the more recent additions. It is built in great part on made ground extending into Lake Michigan. Its chief point of interest is the Chicago Art Institute, the leading art museum of the city. Jackson Park, the former site of the Columbian Exposition, is likewise a place of interest to the lover of outdoors, on account of its golf courses and other grounds for games, but principally for its boating facilities, the many miles of lagoons for which the Exposition was noted being left in almost their original

state, and the islands formed by them are now wooded with apparently their primeval foliage.

A most significant single event in recent years has been the Massachusetts playground law, essentially a local option measure. It requires every city of 10,000 or more inhabitants to vote as to whether or not it would maintain playgrounds. Nearly 100 cities have voted, and over 90 per cent favorably. New Jersey passed an enabling act in 1907 and Ohio in 1908, followed by Minnesota in 1910, and since by over 20 States; by most of these acts the larger cities are empowered to issue bonds to acquire and improve sites for playgrounds and recreation centres. City playground associations have popularized the movement in the cities. Various municipalities have playground commissions which look into the needs of the cities and make plans for the future. Some of the cities with such commissions are Minneapolis, San Francisco, Oakland, Berkeley, Philadelphia and New York. In the last-named city there is a special recreation commission which has inventoried all the recreational facilities of the city and endeavors to make them adequate to actual needs. In Buffalo tramping trips with the playground children have been tried with great success. The Chicago playground association has been conducting similar trips for adults. New Orleans is accepting only such new school sites as have ample play space and is acquiring additional ground adjoining its present school buildings as fast as funds will permit. Cincinnati is also purchasing at great expense plots adjoining its older school buildings. Spokane is making similar provisions for recreational space, as are many other cities, conspicuously Rochester, N. Y. A State law of Washington requires a minimum of 100 square feet of play space per child on all new school sites. Wading pools, swimming pools and field houses are common features that add much to the attractiveness and utility of American playgrounds.

In the United States at present more than 500 cities containing populations of 5,000 or over now possess playgrounds of which about 30 per cent are maintained by voluntary contributions, 20 per cent by boards of education and the remainder in some other way by the municipalities.

The New York board of education maintains about 40 evening recreation centres for young people of both sexes. In these centres the unit of organization is the boys' or girls' club. The aggregate attendance is about 2,000,000, or an average evening attendance of 10,000. Over 100 vacation playgrounds are maintained, while in several congested districts the playgrounds and rooms of schoolhouses are open to mothers and babies of the tenements. In summer the average daily attendance at the vacation playgrounds is 77,000. In relation to recreation piers the department of docks and ferries constructed recreation piers with an upper story used for recreation purposes in eight river-front localities. These piers are open to the public from May to September or October and are maintained at an annual expense of over \$170,000 for music, lighting, attendants, etc. There is a concert on each pier every evening from 8 to 10. The piers vary in size from 300 feet to about 800 feet. On hot Sundays there have been as many as 12,000 peo-

ple on the larger piers. In Cleveland over four-fifths of the 114 public schools have auditoriums, nearly one-third possess gymnasiums, while about one-half have one or more inside playrooms. Provision is made for the club and play activities for the after-class and evening periods which will draw boys and girls off from the street. Recreational and developmental opportunities are afforded for young people's use during leisure time, while adult public discussion of school and civic matters is facilitated in assembly halls. Many of the assembly-rooms are fitted with stereopticons, screens, stages, dressing-rooms and pianos. The after-class and evening utilization of the school edifices has assumed two main forms: (1) regular night-school sessions and (2) lettings to various clubs and organizations for miscellaneous gatherings, entertainments and indoor games. In addition, there are a small number of affairs—entertainments, dances or bazaars—gotten up by or for the pupils of the schools. Public libraries and parks are also adapted to recreational purposes. Pittsburgh's playgrounds and recreation centres comprise 13 plots costing in the aggregate over \$2,000,000. Washington, D. C., has over 30 recreation centres, well equipped and supervised. Newark, N. J., maintains 17 school playgrounds, while Essex County, in which it is located, has a park commission which maintains playfields and outdoor gymnasiums in each of the city's five public parks.

In England, great strides have been made recently in providing recreation. The English are very fond of outdoor life, and provision has been made generally for grounds for cricket, football and golf in the suburban parks of the great cities. In London, the parks within the city are mostly in districts too congested to allow for sports, but the many small squares that have been opened in connection with the extension of streets and boulevards have been adapted to the needs of recreation, in particular playgrounds for children. Great changes have been made in the thickly populated Whitechapel district. Open places have been provided to give breathing space, where children may romp while their parents of the laboring class listen to music. Likewise, the open spaces around churches and schools have been devoted to the same purpose, in many cases suitable playground equipment being provided, along with qualified athletic instructors. When connected with the schools, this instruction is under the teachers. Saint James Park has a shallow wading pool that may be flooded to a considerable depth and used in winter for skating. The greatest recreation park, however, in the city is Victoria Park, Bethnal Green, in the northeast of London. Outside of the greater cities, and in the smaller towns, every inducement is given to sports of all kinds. The new garden cities, of which there are many in connection with the great industrial centres, have been built with the primary purpose of giving every advantage of recreation to their inhabitants, young and old, and playgrounds, public band concerts, bathing facilities, reading rooms, theatres and club rooms have been amply provided.

In Europe almost every city has its facilities for recreation, be it in public playgrounds, public baths, military concerts, or the many other pa-

times that local needs may suggest. In Germany the policy of the city and of the government is to encourage the spirit of outdoor life. Facilities have been provided in the cities on a scientific basis. Figuring on the average size of the German family, it has been estimated that of a population of 100,000, the number of children is from 12,000 to 15,000, and for each thousand of these there should be provided from 30 to 40 acres for recreation purposes. Such plans in effect have been carried out in many cities. Playgrounds have been provided near the centres of congestion. A great proportion of these are located in connection with the public schools, and their control is vested in the teachers, who direct the outdoor exercises of their pupils as a part of the curriculum. As a rule, the children using the playgrounds are divided into groups, each of which has the freedom of the grounds twice a week, Sundays being reserved for students of the apprentice schools. These grounds in connection with the schools are suitably provided with the usual athletic and gymnasium equipment.

Modern ideas of recreation have taken firm hold in France to a great extent, but the French have never been accustomed to outdoor games to the same extent as the English or Americans. Taking Paris as an example, there are many large and small parks and squares where the inhabitants are accustomed to congregate and listen to martial music, but athletics are never of the violent sort. However, in connection with the public school system, in which education is compulsory, gymnastic and outdoor exercise and games are required. In some of the modern and model schools, grounds are fitted out with the most modern equipment with competent instruction. The city has, however, a wonderful system of attractions that further the cause of recreation. The beautiful series of boulevards leading to the Bois de Boulogne and the Bois de Vincennes is an incentive to the inhabitants to walk a great deal, and in the evenings, on Sundays and holidays these two parks are thronged with families that have gone there to spend the day, or even further, to Versailles or Saint Germain, two magnificent parks at some distance from the city. The city has one particular attraction—its numerous small steamboats on the Seine. For a few sous they will carry one far without the city limits to the country, where there are many spots that are the picnic grounds of the Parisians. Within the city are the Gardens of the Tuileries, the great childrens' playground. See also BATHS, PUBLIC; PARKS, PUBLIC.

A., 'Educational Extension' (Cleveland, O., 1916); Parks and Playgrounds Association, 'Statement Relating to Recreation in Greater New York' (New York 1910); Sperling, H., 'The Playground Book.'

RECREATIVE RELIGIONISTS, the name of an association formed in London 1866 for the purpose of providing on Sunday evenings popular lectures on scientific subjects with sacred music at intervals. An effort was made

to suppress the work of the association under the provisions of the "Sunday Act," 21 Geo. III, ch. 49, but it failed, and the Recreative Religionists or Sunday Lecture Society now figures in the registrar-general's report among "sects having registered places of worship."

RECRUITING. See ARMY; ARMY ORGANIZATIONS; UNITED STATES, ARMY OF.

RECTANGLE, in geometry, a plane quadrilateral figure whose angles are all right angles. All rectangles are parallelograms, i.e., have the opposite sides parallel. An equilateral rectangle is a square. A rectangle is said to be contained by any two of the sides about one of its angles; thus, if A B and B C represent two adjacent sides, the rectangle is said to be contained by A B and B C, or, as it is sometimes expressed, it is the rectangle under A B and B C. The area of a rectangle is equal to the product of its base and altitude. Rectangles having equal bases are to each other as their altitudes; rectangles having equal altitudes are to each other as their bases.

RECTIFY, to refine common alcohol or spirit by distillation. The process of rectifying begins after the spirit itself has been distilled, and consists in removing the impurities from the spirit by fractional or repeated distillation, so far as possible, for it is impossible in this way to get rid of fusel oil. Whisky, brandy and rum, if genuine, are made from rectified spirit. To rectify, in geometry, means to construct a straight line equal in length to a definite portion of a curve; to rectify the globe, in astronomy or geography, means to bring the sun's place in the ecliptic on the globe to the brass meridian or to adjust it in order to prepare it for the solution of a prepared problem. See DISTILLED LIQUORS.

RECTOR, specifically, one who rules, governs or administers. In the Established Church of England a clergyman who has the care of a parish and has the parsonage and tithes—the clergyman of a parish where the tithes are not inappropriate, as distinguished from a vicar; in the Roman Catholic Church, the head of a religious house; among the Jesuits, the head of a house that is a seminary or college; in Scotland, the head-master of an academy or important public school; in France and Scotland, the principal of a university; in England, the heads of Exeter and Lincoln colleges, Oxford. The canonical signification of the term, strictly, is a clergyman appointed to govern a parish where the chief parochial jurisdiction was vested in a religious corporation or in some non-resident dignitary. In some monastic orders the term is applied to the head of a convent. Consult Phillmore, 'Ecclesiastical Law'; Cripp, 'Law of the Clergy'; Whitehead, 'Church Law.'

RECTORITE, a clay, or hydrated aluminum silicate similar to kaolinite, mined in Garland County, Arkansas.

RECTUM, the lower portion of the large intestine or colon. The term, however, is a misnomer so far as the human anatomy is concerned, for the bowel adapts itself to the curves of the sacrum and at one point doubles upon itself. The rectum is from six to eight inches long, extending from the sigmoid flexure to the anus, and is narrowest at its two extremities.

The largest and most dilatable portion (ampulla) just above the levator-ani muscle, forms a sort of pocket in which faeces, etc., lodge. The rectum has a mucous coat (membrane), gathered into transverse folds (Houston's valves), forming compartment-like spaces; a submucous and a muscular coat; and at the upper portion, where there is little motion, a peritoneal coat (mesentery).

The tendency of specialists is to consider the rectum as only that part of the bowel below the third sacral vertebra and devoid of mesentery, and to divide it into two portions, the fixed rectum and movable rectum. The rectum is in close opposition with large pelvic vessels and nerves and a portion of the small intestine; also, in the male, with the bladder, urethra and prostate gland, and in the female, with the uterus, vagina and Douglas' cul-de-sac. Its lower portion is surrounded by the hæmorrhoidal plexus of veins. The vessels forming this plexus, as also those of the vaginal and vesico-prostatic plexuses, are very large, frequently communicate and have many valves. It is in the lower portion of the rectum that hæmorrhoids or piles and many other painful affections occur, as blood-vessels and nerves are numerous and the muscles powerful.

Diseases of the Rectum.—These include congenital imperfections. The rectum may even be absent, or partially developed, terminating in a blind pouch; or it may abnormally open into the bladder, vagina, uterus or urethra. These imperfections can be usually remedied by the surgeon.

Threadworms or pinworms frequently inhabit the rectum and cause itching about the anus (*pruritus ani*). They may be destroyed by injections of lime-water or a solution of ox-gall. Abscesses (caused by blows, perforation, sitting upon cold, damp seats, etc.) may form in the loose areolar tissue about the lower part of the rectum and open externally or into the rectum, leaving a fistulous tract (*fistula in ano*). Benign tumors, fibroma, papilloma and adenoma and also carcinomatous and sarcomatous tumors may form in the rectum. Hæmorrhoids, due to disease or a weakened condition of the hæmorrhoidal veins, are common, especially in persons who are on their feet a large part of the time and who are engaged in sedentary occupation. Hæmorrhoidal affections may be relieved by astringents or by operation. Polypus of the rectum (soft and hard), comparatively frequent in childhood, is a tumor resembling in shape a berry or a pear and having a peduncle. It sometimes bleeds and protrudes at the anus after stool. It is composed of elongated follicles and a network of small blood-vessels. It may be removed by a ligature or by an appropriate instrument. Prolapsus of the rectum, due to a relaxed state of the sphincter-muscles and the coats of the rectum, may be either incomplete or complete, with protrusion from the anus (*prolapsus ani*). It is observed generally in young children and women, and is brought on by bearing-down strains. Treatment requires the replacing of the bowel and keeping of it in place, and astringents, caustics and operation are employed as may seem advisable. Stricture of the rectum or narrowing of its calibre may be very limited in extent or may include a con-

siderable portion of it, and is due usually to malignant or syphilitic ulceration. The symptoms include difficult defecation, more or less purulent and bloody discharges and pain. If not relieved, it affects the general health. Treatment consists of dilatation with rectal bougies or division of the cicatricial tissue by instruments (colotomy). Ulceration of the rectum may be due to simple inflammation or to dysentery, tuberculous disease, syphilis or malignant disease. Symptoms vary with the character of the sores and their location. There are usually discharges of pus, blood and mucus, and some pain and tenesmus. Treatment depends on the nature and extent of the disease and the constitutional condition of the patient. It includes the keeping of the bowel as quiet and free from faecal matter as possible, the use of simple food, saline aperient and vegetable astringents or nitrate of silver. Fissure of the anus or a tear of its mucous membrane may extend into the rectum or a fissure of the rectum may exist by itself. In either case the fissure is usually produced by the passage of hardened faeces and the attendant straining. It is sometimes obstinate. Treatment calls for regulation of the bowels, dilatation and the application of nitrate of silver or other astringent. Neuralgia of the rectum is sometimes mistaken (before an examination of the rectum is made) for fissure. Treatment is as in other neuralgias, except when it is caused by pressure of a displaced coccyx upon sacral nerves. This bone must then be replaced or removed.

Intestinal calculi (*enteroliths*), gallstones and faecal concretions containing, it may be, fruit-stones or berry-seeds, are occasionally found in the rectum. They give rise to more or less tenderness and abdominal pain, severe and intractable constipation, cold perspiration, vomiting, thready and rapid pulse, etc., and they must be removed. Invagination or intussusception of the rectum, of the upper portion into the lower, as the result of strain and weakened rectal walls, requires surgical aid.

Regular and free movements of the bowels, unattended by straining, are of the greatest importance in the treatment of most rectal ailments and preventive of many. The fact that the lower portion of the rectum is capable of holding a large amount of hardened faecal material, while the more liquid matter readily flows by it and out of the body, is not generally understood. Consult Lynch, J. M., 'Diseases of the Rectum and Colon' (Philadelphia 1914) and 'Reference Handbook of the Medical Sciences' (New York 1916).

RECURRING SERIES. See SERIES.

RECUSANTS, *rêk'û-zants* or *rê-kû'zants*, a term in use under the penal laws of England, when it was sought to force the consciences of the people by legal punishments. *Recusants* were those persons who refused or neglected to attend divine service on Sundays or holydays in the Established Church or to worship according to its forms. The word is first met with in temporal courts in the first year of Queen Elizabeth, when it was enacted that all persons who, without reasonable excuse, failed to attend some usual place of prayer, should be censured and fined for every offense 12 pence. In 2 Elizabeth the fine was made for every month

£20, and later in the same reign it was enacted that if recusants did not submit within three months after conviction they might, upon the requisition of four justices of the peace, be compelled to abjure and renounce the realm, and if they did not depart or if they returned without due license, they were to be treated as felons, and suffer death without benefit of clergy. In the case of Roman Catholic recusants the laws were more severe. They were liable to a forfeit of 100 marks (£66 13s. 4d.) for hearing mass; for saying it the fine was doubled and in both cases they had to undergo a year's imprisonment. They were disabled from taking lands either by descent or purchase after the age of 18, unless they renounced their errors, and could not keep or teach schools under pain of perpetual imprisonment. After a first conviction they could not keep arms in their houses, could not appear within 10 miles of London, could not travel five miles from home without license, could not hold any public office, could not have marriage, baptism or burial performed, except by a minister of the Established Church; could not bring any action at law or equity, all under penalties of fine and imprisonment. By the Toleration Act (1 William and Mary, ch. 18) all persons dissenting from the English Church, except Roman Catholics and anti-Trinitarians, were allowed to meet for purposes of worship according to their own forms on taking the oaths of allegiance and supremacy. The act was extended to include Unitarians in 1813 and in 1829 the Catholic Emancipation Act granted toleration to Roman Catholics.

RED, one of the three primary colors. Mixed in equal strength and proportion with the other primaries, it yields secondaries, for example, with yellow it forms orange; with blue, violet, etc. Also a pigment. The most useful red pigments are carmine, vermillion (sulphuret of mercury), chrome-red, scarlet-lake (biniodide of mercury), madder-lake, light red, burnt sienna; these are yellow reds. Venetian red, Indian red (carbonate of oxide of iron) and crimson-lake are blue reds. Red pigments are derived from the three kingdoms of nature, viz.: carmine from the cochineal insect, the lakes and madders from the vegetable world and the others from the mineral world.

RED ADMIRAL, a butterfly of the genus *Vanessa*, especially *V. Atalanta*, so-called by British collectors. See **ADMIRAL**.

RED-BACKED MOUSE, a small, chestnut-backed wood-mouse (*Eutamias gapperi*) closely related to the meadow-mouse (*Arvicola riparius*), which is common throughout the eastern half of the United States and in the Saint Lawrence Valley and has the general habits of a meadow-mouse.

RED-BACKED SANDPIPER, the dunlin (q.v.).

RED BANK, N. J., town in Monmouth County, on the Shrewsbury River, at the head of navigation, and on the Central of New Jersey, the New Jersey Southern and the Pennsylvania railroads about 25 miles south of New York. It has regular steamer connection with New York, Atlantic Highlands and other ports. Settlements were made in the vicinity in 1650, by English and Dutch colonists. It was

incorporated as a town in 1872. It is an attractive residential town and a favorite summer resort. It has a number of industrial establishments, chief of which are a large canning factory, carriage shops, clothing factory, boiler works, gold-beating works and brush factory. About 500 persons are employed in the factories. The trade is chiefly in manufactures, farm products and fruit. It has nine churches. The educational institutions are the Shrewsbury Academy, several private schools, a high school which cost \$60,000, public and parish schools and a public school library. The government is vested in a board of commissioners of five members, elected annually. Pop. (1890) 4,145; (1900) 5,428; (1910) 7,398; (1915, State census) 8,631.

RED BAT, a small reddish bat (*Lasiurus borealis*) common in the temperate parts of North America; length about two inches; fur long and silky, generally light russet, tinged with yellow, darker and richer on the back. See **BAT**.

RED-BELLIED HAWK. See **RED-SHOULDERED HAWK**.

RED-BELLIED SNAKE, a harmless snake (*Storeria occipitomaculata*) of the Eastern United States, whose belly is salmon red. It is dull brown above, with a paler stripe along the spine, bordered by one or more rows of blackish dots; a constant feature is three pale reddish blotches on the occiput. Its size and habits are similar to those of the garter-snakes. Two or three other species in the West have red bellies and are sometimes locally known by the same name.

RED BLUFF, Cal., city and county-seat of Tehama County, 120 miles northeast of Sacramento, on the Sacramento River at the head of navigation, and on the Southern Pacific Railroad. The district produces wheat, lumber and wool, and there are canneries, fruit-drying and packing plants and flour mills. Pop. 3,530.

RED BOOK, an English government book containing the names of all persons in the service of the State; also an official publication of the Austro-Hungarian government giving its views on the Austro-Servian controversy shortly after the opening of the World War in 1914.

RED-BREASTED, or **ROBIN**, **SNIP**, a dowitcher (q.v.).

RED BUG, or **COTTON-STAINER**. See **COTTON INSECTS**.

RED CEDAR. See **CEDAR**.

RED CLOUD (MAQ-PE-YAH-LUTA), Sioux Indian chief: b., according to his own testimony, 1822; d. Pine Ridge, S. D., 8 Dec. 1909. He first came into prominence as leader of the Indians in the Fetterman massacre near Fort Phil Kearny, Wyoming, in December 1866. In this event 100 men under Captain Fetterman and Lieutenant Brown, comprising the entire command, were slain. Red Cloud then became the acknowledged leader of the warrior Sioux, established a military dictatorship and terrorized the region over which he ruled. He was a much more powerful leader than the somewhat famous Sitting Bull, though he was not a hereditary chief, but rose to distinction through his inborn qualities. In 1874 the Indians aban-

doned the North Platte country and went to the Red Cloud Agency on the White Earth River, whence they continued under Red Cloud to make frequent raids. In 1880 he made a treaty of peace with the government which he faithfully observed.

RED CLOUD, Neb., precinct and city, county-seat of Webster County, on the Republican River and on the Chicago, Burlington and Quincy Railroad, about 110 miles in direct line southwest of Lincoln. It is in an agricultural and stock-raising region. The chief manufacturing establishments are flour mills and machine shops. It has large lumber and stock-yards and grain elevators. Its chief shipments are livestock, wheat, corn, vegetables and flour. Pop. precinct, 2,329; city, 1,686.

RED CROSS, Order of the Royal. 1. A decoration instituted by Queen Victoria, 23 April 1883, to be conferred on women, not necessarily British subjects, rendering distinguished service in the care of sick and wounded soldiers and sailors. The badge is a cross of enameled crimson edged with gold, bearing the words Hope, Faith and Charity and the date on the arms. The centre has a gold circle with the queen's effigy in relief. 2. A Russian Order of the Red Cross was instituted in 1878 and conferred by the empress upon women.

RED CROSS SOCIETIES, a general name for those societies founded for assisting the wounded in time of war, so named because their distinctive badge is a red cross on a white ground. Such societies have been established in all civilized countries as a result of an international conference held at Geneva in 1863, which was followed next year by an international convention agreed upon at the same place, at which the International Treaty of Geneva was accepted and signed by a number of different nations. According to this all hospitals and hospital officials and all in any way engaged in attending the sick and wounded in war are treated as neutral parties. The society in England has four branches, two ambulance branches, one volunteer nursing branch and one branch to raise funds and supplies, and societies in other countries. There is an international committee at Geneva which serves as a centre of communication between the different Red Cross societies throughout the world. In connection with this may be mentioned the decoration of the Royal Red Cross instituted by Queen Victoria in 1883, as a reward for women who have exerted themselves in aid of sick and wounded soldiers and sailors in time of war. The enameled crimson-and-gold cross bears the words "Faith, Hope and Charity," with the effigy of her majesty, the royal and imperial cipher, etc., and is attached to a blue ribbon and worn on the left shoulder.

The first war to bring the Red Cross service into activity was that of 1866 in Germany, Austria and Italy. Austria had not yet joined the compact, but her citizens raised and gave to the service almost \$500,000. Germany's societies supplied over \$3,000,000 and 500 volunteers, men and women, entered the service. The Red Cross work during the war proved the incalculable value of the organization. The next call on the service was the Franco-Prussian War. In Germany more than 2,000 committees were formed at the beginning of the conflict,

with a central committee at Berlin. More than \$14,000,000 was raised and used. France had less resource in readiness, but she raised and used nearly \$2,000,000, and her service cared for more than 100,000 wounded men. The next demand on the Red Cross was in 1876-78, when Turkey, Serbia, Montenegro, Greece and Russia became embroiled. In the beginning of this period of its work the Red Cross service was regarded with suspicion by the military, but was soon solicited to take control of its treaty-province. It raised almost \$17,000,000 and applied over \$13,000,000.

The Red Cross emblem found its first opposing force in Turkey. The Turkish soldiers regarded it as of religious significance and so violent was their prejudice that a red crescent was substituted in order to secure speediest recognition and co-operation. In the Japanese army the Red Cross service has been wonderfully effective. In 1886 Japan entered into this international treaty, and the mikado became president of a Red Cross Society in a civil capacity. In the Turko-Russian contest, in the Tunisian, the Tonkin and the Madagascar wars, the Red Cross was notably active. In the Græco-Turkish campaigns its work and sacrifice were heroic.

National Red Cross.—This is an American body incorporated under the laws of the District of Columbia, 1 Oct. 1881, reincorporated 17 April 1893, and reincorporated by act of Congress June 1900; for the relief of suffering by war, pestilence, famine, flood, fires and other calamities of sufficient magnitude to be deemed national in extent. The organization acts under the Geneva Treaty. The United States gave its adhesion by act of Congress 1 March 1882; ratified by the Congress of Berne 9 June 1882; proclaimed by President Arthur 26 July 1882; headquarters, Washington, D. C. The introduction and development of the Red Cross movement in the United States were chiefly due to Miss Clara Barton, the founder of the American branch. Previous to the organization of this branch there were many members of the Red Cross Society in the United States with Miss Barton as their representative. When the national branch was regularly formed Miss Barton was chosen leader. In the United States no laws have been passed to regulate Red Cross work. The national branch has no sub-societies or sub-committees; but patriotic and sympathetic men and women as individuals, or united in societies, are at liberty to assist and to co-operate with the Red Cross in raising money and in providing nurses and whatever the service requires. Whenever needed, this co-operation is active in every State and in most of the Territories.

The American National Red Cross did relief work in the Russian famine of 1892, and in Armenia in 1896.

The Red Cross work in Cuba during the war, as measured by service and contributions was phenomenal. The total value of gifts, including cash donations, reached nearly \$4,000,000. When peace was declared, there yet remained starvation, sickness, disease, destitution and desolation on the island. The Red Cross continued indefatigable in its work. In all its Cuban undertakings volunteer assistance and contributions of supplies were received from France, England, Belgium, Holland, Switzer-

land, Germany, Italy, Denmark and Mexico. The American National Red Cross also rendered efficient aid after the following disasters: Johnstown flood, 1889; Galveston flood, 1900; San Francisco earthquake and fire, 1906; Cherry Mine disaster, 1909; Chinese famine, 1910; Italian earthquake, 1908; Minnesota forest fires, 1910; Luzon eruption, 1911; Triangle waist factory fire, 1911; Titanic sinking, 1912; Mississippi flood, 1912; Ohio flood, 1912; Salem (Mass.) fire, 1914; Eastland disaster, 1915; Indiana cyclone, 1917, and many minor casualties. In the Mexican guerrilla warfare and the Balkan Wars the society was also active as well as in Manchuria, in the pneumonic plague.

National Support.—The governments of the United States, Great Britain, Germany and Italy give no regular financial support to the Red Cross societies. In 1882 Congress appropriated \$1,000 for printing Red Cross literature; and since then, from time to time, has appropriated various sums for special purposes. Before the war, in Germany the government granted the society permission to hold occasional lotteries to secure funds. France allowed an indemnity of 20 cents a day for each sick or wounded soldier cared for by the society in time of war. The Netherlands government paid the salary of the secretary, provided office quarters, allowed \$400 a year for office expenses, paid the traveling expenses of an officer whose duties in connection with the work of the society may necessitate his leaving his home. Belgium gave financial support in time of war. Denmark contributed annually \$1,000. Austria gave \$2,400 annually for assistance in case of epidemics or great calamities. Switzerland appropriated \$5,000 annually for a special purpose. The emperor and empress of Japan gave annually \$1,250. Russia paid for men taken care of by the society in time of war, at a rate agreed upon with the minister of war. In 1900 the emperor sanctioned a tax of two and one-half cents on certain railroad tickets and \$2.50 on passports, such extra tax to be for the benefit of the Red Cross Society. The membership of the society just before the war was approximately as follows: In the United States, 298 members of the National Society; France, 55,000; Austria, 52,209; Hungary, 42,041; Japan, 894,814; Germany, main branch and affiliated societies, 300,000.

The American Red Cross has experienced a tremendous development growing out of the World War. In May 1917, President Wilson, as the head of the organization, appointed a war council to supervise its activities. The members were Henry P. Davidson (of J. P. Morgan and Company), Charles D. Norton, Cornelius N. Bliss, Jr., and Grayson M. P. Murphy of New York; and John D. Ryan, of Butte, Mont.; also (ex officio) William Howard Taft and Eliot Wadsworth (chairman and vice-chairman of the executive committee). By proclamation the President made the week of June 18-25 the period for a nation-wide campaign for funds, and this resulted in the raising of over \$100,000,000 for Red Cross work. During the five months, May to October inclusive, the membership rose from less than 500,000 to 5,000,000, and the number of chapters from 582 to 2,736. Arrangement was made by which the medical department of the army gave rank to leading Red Cross officials as

follows: Chairmen of central committees and war council were created major-generals; members of the war council were made brigadier-generals; the director-general was commissioned a colonel, and his assistant and the commissioner, lieutenant-colonels; while the various Red Cross directors were assimilated as majors. Harvey D. Gibson, president of the Liberty National Bank of New York, was named as general manager of the Red Cross at Washington, with colonels under him as director-generals of the various activities. The chapters throughout the country were gathered into 14 divisions, under division managers: New England, office Boston; Atlantic, office New York; Pennsylvania, office Philadelphia; Potomac, office Washington; Southern, office Atlanta; Lake, office Cleveland; Central, office Chicago; Gulf, office New Orleans; South-western, office Saint Louis; Northern, office Minneapolis; Mountain, office Denver; North-western, office Seattle; Pacific, office San Francisco; Insular and Foreign, office Washington, D. C.

The workers in the chapters manufacture surgical dressings, hospital supplies, knitted garments and comfort kits. Through the bureau of supplies they receive their materials at cost. The war council and most of the important positions command no salaries; all time is given free, except routine workers, many of whom receive small salaries to provide their living. The individual chapters each deliver their productions to the warehouse of their division. Major Grayson M. P. Murphy was one of the first to reach France, where he established American Red Cross headquarters in Paris, and made the arrangements to serve the American troops. He was made a member of General Pershing's staff to facilitate his work. A program was laid out to work in harmony with the Young Men's Christian Association, which also had headquarters in France. Hospital units were systematically organized, with a minimum personnel of 241, and mustered into the United States Army Medical Corps. Each unit was designed to serve at least 500 patients. Nearly 50 such hospital units had been organized by 1 Jan. 1918. This quick work would have been impossible, had it not been laid out and started long before America's entrance into the war. The Red Cross organization is rightfully proud of the fact that within six weeks after the President's declaration that a state of war existed, they had six hospital units ready, which were the first detachments of the American army to join the Allies. Their efforts were by no means confined to caring for American troops. They had a chain of warehouses and motor trucks, that was supplying (Jan. 1918) 3,500 war hospitals in France. They served hot meals to allied soldiers at the railway stations, furnished bathing, disinfecting and resting facilities for the men who had retired from the trenches to recuperate, and did an immense amount of useful service. Especially did they care for refugees and mutilated soldiers. They housed the refugees who came in, looked after their health and started them in the work of rebuilding destroyed villages and the like. These activities were of course handled in co-operation with the French government, so that the work was harmonious with their own. Special efforts

were also put forth to aid orphans, lost children and babies for whom support was not provided. Because of the distressingly low French birthrate, and increased mortality, this work was of importance, and three groups of children's specialists were formed, a part of whose duties was to aid prospective mothers, and to make healthy children of the babies that were born. The German government shipped out of their lines practically all of the inefficient French population, and most of these found their way back to France via Switzerland. The American Red Cross helped an immense number of refugees, and carried on this work until a considerable time after the close of the war. They established a vast system for bringing in not only hospital supplies, but clothing and food. The shipping board co-operated to assist them, and they sent supplies and medical relief to nearly all the Allies, except Great Britain. Most of the cargo space for these supplies was donated by the steamship companies, army transports accommodated them and passenger rates for Red Cross workers were placed at the lowest possible figure.

The total American Red Cross war appropriations in France up to 15 Oct. 1917 was a little over \$15,000,000, and in other European countries nearly \$4,000,000, while the United States work had cost nearly \$8,000,000. Of this Russia got \$323,000, Roumania \$247,000, Italy \$210,000, Serbia \$223,000, England \$17,000, Armenia \$638,000, Belgium about \$300,000. The sums appropriated to these countries by the close of 1917 were about double these amounts. By arrangement with Germany the Red Cross shipped food supplies regularly to Allied prisoners in German territory and 95 per cent of these are properly receipted for by the prisoners of war themselves. It is believed that the principal dependence of many of these prisoners for food, as well as small change, was on the "every fifth day" shipments of the Red Cross.

In the training camps for soldiers in the United States the Red Cross has also been active, maintaining a bureau of sanitary service, and looking after their comfort and welfare in a hundred minor ways. Ambulance corps were provided as fast as called for, and the hospital work was efficient. There is a great corps of home workers in the Red Cross, and a part of their activities consisted in looking after soldiers' families, who for any reason were improperly provided for. At the personal request of President Wilson, the Red Cross entered into co-operative arrangements with various other relief societies, to avoid duplications and omissions of service. Among these were the National Surgical Dressing Committee, the Needlework Guild of America, the War Service League of the Salvation Army, the American Fund for French Wounded, the American Committee for the Relief of French War Orphans, and in France the American War Relief Clearing House, American Distribution Service and Les Tuberculeux de la Guerre.

RED DEER, or STAG, the common deer (*Cervus elephas*) of Europe and western Asia, which is typical of the family, and the ordinary "deer" of literature and poetry as well as of the chase. It much resembles the American wapiti, but is smaller and rather darker in general color. A fine specimen will stand four feet tall at the fore-shoulder and will weigh about 300 pounds, but exceptional ones have weighed much more. Even larger are those of the Asiatic border and Asia Minor. The antlers of Scotch and Irish stags rarely exceed 33 inches in length; but those of eastern Europe and Siberia are far longer. Several different names have been given to the related deer of northern Asia, but they seem to be essentially the same as those of Europe, where they survive sparsely and under legal protection in almost all the countries. In the British islands the wild red deer remains only in the Highlands of Scotland, but is "preserved" on many large estates and protected moors in both England and Ireland. The species is supposed to have been originally introduced into England from France, where it became very numerous, but since the 17th century it has been killed off in most parts of that kingdom to make way for the fallow deer, the venison of which is far superior, and the animal itself of a more manageable and placid disposition.

The stag has a fine eye, an acute sense of smell and a good ear. When listening, he raises his head and erects his ears. When going into a coppice or other half-covered place, he stops to look round him on all sides, and scents the wind, to discover if any object be near that might disturb him. Though a simple, he is a curious and crafty animal. When hissed or called to from a distance, he stops short, and looks steadfastly, and, with a kind of admiration, at horses or men; and if the latter have neither arms nor dogs he moves on without betraying any symptoms of alarm. He eats slowly; and after his stomach is full, he lies down and ruminates at leisure.

In winter and spring this animal rarely ever drinks, the dews and tender herbage being sufficient to satisfy his thirst; but during the parching heats of summer, he not only frequents the brooks and springs, but searches for deep water wherein to bathe and refresh himself. He swims with great ease and strength, particularly when he is in good condition, his fat contributing to his buoyancy. His voice is stronger, louder and more tremulous in proportion as he advances in age; and during the rutting season it is really fearful. The cry of the hind, or female, is not so loud as that of the male. The pairing season is in August; the time of gestation is between eight and nine months; and she seldom produces more than one at a time. The usual season of parturition is about May, and at that season the hinds are very cunning in concealing and tending, and exceedingly courageous in defending their young, which are exposed to many enemies. The "calf" (as the fawn is called by gamekeepers)

never quits the dam during the whole summer; and in winter, the hind, together with all the males under a year old, assemble in herds, which are more or less numerous in proportion to the mildness or severity of the season. At the approach of spring they separate, none but those of the age of one year remaining associated. Stag-hunting, as carried on in the Highlands, is a sport capable of rousing all the manly ardor and energy of youth and manhood. The beauty, graceful and magnificent bearing of the animal, his sagacity in evading the stratagems of the hunter, or deer stalker, and his courage when at bay, add greatly to the pleasure of the chase. When the stag stands at bay, his effort is to do so in a river or lake, where he has a great advantage over the dogs, for he firmly stands and holds his position, whilst they swim powerless around him. On land, even, a stag at bay has great advantage over the hounds, who exhaust themselves with their clamor, while he is in a comparative state of rest, and recovers his wind. In stalking deer, the animal is generally shot; but if he is only wounded, and has power to fly, then the dogs are slipped to the pursuit. But, in olden times, the chief reliance for pulling and killing the deer was in the dogs; and the fleetness and courage of their hounds were the pride of nobles and kings.

At the present day another sort of stag hunting takes place near Windsor Castle and in some other parts of England. In this sport, which is contemptuously regarded by many persons, a captive stag is carried in a covered cart to the place where the chase is to occur and then turned loose. After brief interval, called giving the deer "law," a pack of hounds is sent upon his trail, and if the stag has spirit enough to run, the hunters following on horseback have a lively chase across the country, at the end of which the deer is retaken, unharmed if possible and saved to run another day. This is a rather tame tradition of the ancient sport.

From the most remote periods, the stag has been the favorite object of the chase; and the severe forest laws of the earlier Norman monarchs sufficiently attest the importance which they attached to the sport. The afforesting of vast tracts of country, by which not only single cottages were destroyed, but whole villages swept away, and churches desecrated and demolished, was the fertile source of misery to the poorer inhabitants, and of injustice to the ancient proprietors of the soil; and the cruel inflictions of the oppressive laws which were enacted to preserve the deer, increased tenfold the curse arising from this tyrannical passion for the chase,—for it was a crime less severely penal to kill a man than to destroy or take a deer.

The ancient customs and laws of 'Venerie,' that science which our simple ancestors looked upon as one of the first accomplishments of the high-bred noble, and a knowledge of which was essential to his education, were formal and technical to an extreme degree. A few of the terms, betokening the different ages of the stag and hind, are still retained, though somewhat altered. The young of either sex is called a "calf"; after a few months the male becomes distinguished by the growth of the bosssets, or frontal protuberances, on which the horns are afterward developed, which during the first

year are merely rounded knobs, whence he takes the name "knobber." In the second year they are longer and pointed, and are called dags, and the animal has now the name of "brocket." In the third year, the first, or brow antler, has made its appearance, and the deer becomes a "spayed." In the fourth, the bezantler is added, and he is then termed a "stag-gard." He is a "stag" in the fifth year, when the third antler, or royal, appears; and in the sixth, the commencement of the sur-royal, or crown is formed, when he takes the name of "hart," which name he retains through life. At this time he is called a "stag of ten," probably because the branches, including the sur-royal, frequently amount to that number. After the seventh year he is said to be croched, or palmed, or crowned, according to the number of branches composing the sur-royal. The female is a "calf" in the first year, a "brocket's sister" in the second and third, and ever afterward, a "hind."

RED JACKET, American Indian, chief of the Senecas: b. Old Castle on Seneca Lake, about 1751; d. Seneca Reservation, 30 Jan. 1830. His Indian name was Sagoyewatha; he was called Red Jacket on account of the scarlet jacket he always wore, which had been given him by a British officer. He was one of his tribe who served with the British during the Revolutionary War; and was noted as an orator. He became widely known through his attitude toward the treaty of Fort Stanwix in 1784; a council had been called to negotiate between the United States and the Six Nations for the cession of lands, and on the occasion he spoke eloquently against the proposed treaty, but without avail. It was shortly after this that he was elected chief of the Senecas. In 1792 on the occasion of the signing of a treaty of peace between the United States and the Six Nations, Red Jacket had an interview with General Washington, who gave him a silver medal which he always wore afterward. In 1810 he gave information to the agent of the government of the attempt made by Tecumseh to draw the Senecas into the western combination; and in the war with England of 1812 he offered the service of his tribe to the United States, and proved his bravery in several skirmishes. The latter years of his life were passed on the Seneca Reservation; he became very intemperate, and was at one time deposed from the chieftainship on that account. He always opposed the advance of civilization, the missionaries and the work of education among his people. Consult the 'Life' by W. L. Stone.

RED JACKET, Mich., village in Houghton County, on the Chicago, Milwaukee and Saint Paul, the Chicago and Northwestern, the Mineral Range and the Copper Range rail-

roads, about 15 miles north of Houghton. It is in the famous copper region in northern Michigan, near Lake Superior. Its industries are connected with the mining of copper and preparing it for market. Pop. (est.) 4,700.

RED-LETTER DAY, in the Roman Catholic Church days set apart for especially important festivals, and so named because of being indicated in red letters in the old missals and breviaries. Formerly they were so indicated in the calendar of days in the Book of Common Prayer, and some prayer-books are still printed in this fashion. In general usage the term has come to mean especially fortunate or auspicious days in a person's life, or days to be remembered because of some important event or benefit.

RED LINE MAP, a map which attracted considerable interest about the time of the dispute between the United States and England over the boundary line between Canada and Maine. It was made by the Frenchman D'Anville in 1746. It had been sent to Vergennes, the French minister, by Franklin in 1782, and was discovered among the Paris archives by Jared Sparks. A strong red line drawn near the ridge, in which the Kennebec and Penobscot rivers rise, more than favored the English claims, respecting the northeast boundary of the United States. Sparks sent it to Webster, then Secretary of State, who was anxious lest the English should hear of it. It was used in a secret session of the Senate, and with the Maine commissioners to induce a ratification of the treaty, and was afterward made a ground of reproach against Webster by opponents of the treaty.

RED LODGE, Mont., city and county-seat of Carbon County, 170 miles southeast of Helena, on the Northern Pacific Railroad. It is situated in a district with deposits of coal, gold and silver; and farming and stock-raising are also carried on. The city's chief business is as a shipping centre. Altitude, 5,500 feet. Pop. 4,860.

RED MEN, Improved Order of. See IMPROVED ORDER OF RED MEN.

RED OAK, Iowa, city, county-seat of Montgomery County, on the Nishnabotona River, and on the Chicago, Burlington and Quincy Railroad, about 48 miles southeast of Council Bluff and 38 miles east of the Missouri River. It was founded in 1857. It is in a fertile agricultural and stock-raising region; and its industries are connected chiefly with farm products. The chief industrial establishments are flour mills, machine shops, creameries, lumber and brick yards, and stock yards. The city has 13 churches, six schoolhouses, county courthouse, municipal buildings, and several good business blocks. The three banks have a combined capital of \$200,000. Pop. 4,830.

RED RIDING HOOD, Little, a popular nursery story of a little girl going to visit her grandmother and being eaten by a wolf disguised as the grandmother whom he had previously devoured. The story has many versions, but that of Perrault, 'Le petit chaperon' in 'Contes du temps passé' (1677) forms the base for most of them. The brothers Grimm use the tale but in their version Red Riding

Hood is rescued through the timely arrival of some woodsmen who cut open the wolf and release her.

RED RIVER, a large river of the United States, the southernmost of the great tributaries of the Mississippi River. Its headwaters are in the northwestern part of Texas, on the eastern edge of the Llano Estacado, and it flows east-southeast, forming the boundary between Texas and the Indian Territory and the northeastern boundary of Texas, entering Arkansas at the southwest corner of the State. After entering Arkansas it turns south and pursues an exceedingly irregular course to Shreveport, La., where it again takes a south-east course to Avoyelles County, making a large northern curve in crossing this county, and entering the Mississippi River opposite the southwest corner of the State of Mississippi. The mouth of the Red River is about 340 miles from the mouth of the Mississippi River. The whole course is nearly 2,000 miles. The chief tributaries are the Washita, which joins it in Louisiana; and the False Washita and the Kiamich, both of which it receives in the Indian Territory. Much of its course is through rich prairies, with red soil which colors the water. About 100 miles above Natchitoches, which lies 100 miles above the mouth of the stream, commences a swampy expansion of the river called the Raft, 70 miles long and 20 miles to 30 miles wide, produced by the river dividing into a number of channels, sometimes shallow, which have been obstructed by fallen trees and other matter brought down by the stream. At great expense this obstruction has been cleared away so far as to admit the passage of steamboats. About four miles above Natchitoches the various channels again unite, soon, however, again to separate into numerous creeks and bayous. Above Shreveport was another such Raft, about 32 miles in length. In 1873 a channel was cut through, making this part of the river navigable, but constant care is exercised in removing the floating timber so as to keep the stream open. In the upper part of its course it flows through lofty cañons whose perpendicular sides are from 300 to 800 feet in height. After leaving the cañons it enters the sandy lands, where the waters extend out to a shallow stream from 500 to 3,000 feet in width. Then as it enters the wooded country the stream becomes sluggish and spreads out for miles.

A peculiarity of the lower course of the river is the bayous which it sends out. Some of the bayous return to the main stream and others flow directly to the Gulf of Mexico. The Atchafalaya River originally left the Mississippi at a great bend below the mouth of the Red River; but the Mississippi has cut across the bend, forming Turnbull Island, and here the Red occupies the channel once the Mississippi, and flows south of the island, so that the head of the Atchafalaya is now in the Red River, from which it flows south to the Gulf. The Mississippi receives the flood much earlier than the Red River, and at that time the Mississippi floodwaters flow back past Turnbull Island and down the Atchafalaya. The floodplain of the Red River in Louisiana extends along the river until it is merged into the floodplain of the Mississippi at the mouth of the Black River. This plain is from 10 to 20

miles wide and is known as the Red River bottoms. The plain is below the level of the river and is protected by levees. The river bed above Natchitoches has changed. Many years ago the river left the old bed and cut a new way for itself, a channel about 20 miles long. The new channel is called Bon Dieu River and the old channel is called Cane River. The government is improving the navigation of the Red River and engineers have worked to force all the waters of the Red River into the Mississippi; thus cutting off Atchafalaya. The river is navigable for nearly 1,300 miles and with its tributaries, over 2,000 miles. Small steamers can ascend almost to the Texas boundary at high water and to Shreveport at all seasons except when the water is very low. Consult Marcy, 'Exploration of the Red River of Louisiana.'

RED RIVER, or **SONG-KOI**, a river of Tongking, formed by the junction of the Leteen and Song-shai, the former rising in the Yun-nan province of China, the latter in Laos. It flows southeast, passes Hanoi and after a course of about 700 miles falls by several mouths into the Gulf of Tongking. The river is navigable to Lao-kai, on the border of China and Tongking and along it the French have developed a trade with the Chinese.

RED RIVER CAMPAIGN. In 1864 General Banks, to reduce Texas, asked for reinforcements in order to take in rear the Confederate works at Galveston and the mouth of the Brazos; but Halleck advised operating by way of the Red River, capturing the Confederate depot and dockyard at Shreveport and repossessing western Louisiana and Texas at a blow. The Mississippi squadron under Porter was to co-operate; the army must be back for the trans-Mississippi operations of spring and summer; but no movement could be made till the spring rains had raised the Red, with only four feet at low water and full of obstructions. The fleet left Vicksburg 10 March and landed A. J. Smith's troops at Simsport on the 13th; General Franklin had already come up and driven Gen. Dick Taylor from Fort De Russey guarding the stream; the fleet passed up without opposition; and on the 15th and 16th the forces met at Alexandria. But the Union movements were difficult of co-ordination; Banks did not arrive till the 26th, the rest of Franklin's corps on the 28th. Meantime the Confederates had strongly fortified Shreveport and placed several gunboats there. Banks, with Franklin, went by land to Natchitoches, routing a Confederate force at Cane River on the 28th; Smith's command went by the river in transports, to Grand Ecore, four miles below, arriving 3 April, the day after Banks. On the 8th and 9th Banks advanced by a road away from the river; the Confederates had laid a V-shaped ambush for him, and his command of 8,000 men was utterly routed and would have been annihilated but for reinforcements from Franklin, 2,000 being killed or wounded (battle of Mansfield); Banks retreated; the next day the Confederates advanced, but were met by a counter-ambush of Franklin's and one wing of their army was driven back with heavy loss. But the other wing was so successful that the Federals retreated that night and hurried on to Grand Ecore and finally to Alexandria, abandoning

the campaign. Meantime the fleet was caught in the falling water of the Red and would have fallen into the hands of the Confederates but for the engineering skill and resolution of Lieut.-Col. Joseph Bailey, who built a dam of stones and logs, which raised the river and floated all the vessels down with a narrow escape from destruction.

Banks' army in this campaign numbered 31,303; but after detaching two divisions sent to different points, he had a marching column of 25,736 officers and men of all arms. His losses, including those lost on the retreat from Alexandria, were 454 killed, 2,191 wounded and 2,600 captured or missing, a total of 5,244. Taylor's Confederate army numbered 11,000 and its total losses in the campaign were 3,976 in killed, wounded and missing. See SABINE CROSS ROADS.

JOSEPH T. DERRY,

Author of 'History of Georgia.'

RED RIVER OF THE NORTH, a stream which has its source among the lakes in the west central part of Minnesota. It first flows south and southwest, then west to the boundary between Minnesota and North Dakota, where it turns north and forms the boundary between the States mentioned. It enters Canada in the province of Manitoba and flows into Lake Winnipeg. Its source is about 1,600 feet above sea-level and its mouth 710 feet. It is nearly 700 miles long, the greater part of its course is in the United States. Its drainage area is about 43,500 square miles, three-fourths of which is in the United States. It is navigable almost to the source. The river and its tributaries have in many parts of the plain cut channels through the clay from 20 to 30 feet deep. The Red River is connected with the Mississippi through its southern branch, Lake Traverse, and the Minnesota River. At high water small steamers can pass from the Red River to the Mississippi. It is connected with Hudson Bay by means of Lake Winnipeg. A number of small rivers enter the Red River from Minnesota and North Dakota. The largest tributaries from North Dakota are Cheyenne and Pembina. The latter river has its rise in Manitoba. The chief tributary it receives in Manitoba is Assiniboine.

The Red River flows through a productive agricultural region, famous for the quantity and quality of its wheat. The greater part of the basin of this river has been twice submerged beneath the sea, and it was covered with an extensive glacial drift which left an immense lake, now called Lake Agassiz (q.v.), that had an outlet to the Mississippi River. The beaches are still well defined, even those showing the gradual contraction of the lake. The lakes of Manitoba are the remains of this vast lake. The deposits made by means of ice and water have made the Red River Valley an exceedingly fertile region.

RED RIVER SETTLEMENT. Canada, founded in 1812 by the Earl of Selkirk, on the banks of the Red River, and since 1870 forming part of the province of Manitoba (q.v.).

RED ROBE, The. One of the most powerful of the plays of social criticism written by Eugène Brieux is 'The Red Robe' ('La Robe rouge'), produced in 1900. It is a scathing indictment of the system of criminal justice peculiar to France. It satirizes the unscrupu-

lous place-hunting of lawyers who, desiring to rise to judgeships, can do so only by pleasing the people and accumulating convictions of the supposedly guilty. If a crime be committed, the police and the prosecutors must find the criminal, or, failing of this, must fasten the deed upon the innocent, in order to satisfy public demand. The ruin of one such innocent victim is depicted, together with the hideous methods of the chief prosecutor for bullying the poor devil and his wife into submission. Eventually the Basque peasant Etchepare is acquitted through the courage of an honest lawyer who revolts against the trickery of his colleagues and thus forever forfeits advancement for himself. But the unhappy Etchepare is already hopelessly injured in property and reputation and his wife, against whom he has been turned by the villainous Mouzon, when the latter laughs at her claim for reparation, slays him with the knife of one of his victims kept as a trophy. Every incident of the plot of this piece, every scene and every personage is contributory to the central thesis of the dramatist, who has elsewhere confessed: "Had I lived in the 17th century I would have been a preacher; but now I write plays." It should be noted, however, that 'The Red Robe' is far superior in point of structure, characterization and dramatic appeal to such other didactic works of Brieux as 'Damaged Goods' and 'Maternity'; for the dominant idea and purpose are here more artfully embodied in a story that excites emotional interest apart from any doctrine. 'The Red Robe' has been translated in English by F. O. Reed (1915) and A. Bernard Miall (1916) and is discussed in a monograph on Brieux by P. V. Thomas (1913).

FRANK W. CHANDLER.

RED ROVER, The. 'The Red Rover,' Fenimore Cooper's second sea tale, was written in France and published early in 1828 at Philadelphia. Cooper felt that in writing of nautical affairs he must take care to avoid the themes and characters preferred by Smollett and so was at some pains to invent all his details "without looking for the smallest aid from traditions or facts." Actually, his plot follows the romantic mode with fidelity: an imperial-souled hero, wounded in his sensibilities, has long been a successful and splendid pirate under the scarlet flag, but, in spite of his evil deeds, has so much conscience left that he can be converted in a dramatic moment, later to expiate his sins by services to the Revolution. The story itself could not have made 'The Red Rover' one of Cooper's two or three best sea romances, as it undoubtedly is. There must be taken into account also the solid basis of reality exhibited in the book's seamanship, and, not quite so notably, in such persons as the memorable old tar Dick Fid and the devoted negro Scipio Africanus. The book's representations of life in Newport seem less veracious, pointed even though they are with the author's customary sharpness toward the faults of New England. Fortunately, the action takes place largely at sea and is abundantly varied with chases and storms which succeed each other with exciting speed. What secures to the book, however, its position of excellence is something richly imaginative, something finely poetical, about the conception of the sea which colors the

entire narrative. The ocean here plays a great part. It is the voice of the very tumult of nature, which romantically frees men from the narrower limits of existence on land and yet at the same time shapes their characters with a firm and noble discipline.

CARL VAN DOREN.

RED RUSSIAN. See RUTHENIANS.

RED SANDSTONE, an obsolete term in stratigraphical geology, used to designate a group of formations of which a red sandstone of various shades was characteristic. These sandstones, however, were later found to belong to two series, a lower one, the Old Red Sandstone (q.v.), now generally known as Devonian, and an upper one, the New Red Sandstone (q.v.), separated from each other by the formations of the Carboniferous Period (q.v.).

RED SCALE, an insect affecting the orange (q.v.). See also SCALE-INSECTS.

RED SEA, or **ARABIAN GULF** (ancient, *Mare Rubrum*, *Mare Erythraeum*, or *Sinus Arabicus*; Arabic, *Bahr-el-Hejas*), a branch of the Indian Ocean, extending from the Strait of Bab-el-Mandeb, in a north-northwest direction between Arabia on the east, and Abyssinia, Nubia and Egypt on the west, and connected with the Mediterranean on the north by the canal, about 100 miles long, across the Isthmus of Suez. The Red Sea is a comparatively narrow expanse, 1,450 miles long with a maximum breadth on the tropic of Cancer of 200 miles and a general average of about 180 miles, but diminishing gradually at its south and north extremities; at the former, across the strait it has a width of only 14½ miles, further subdivided by the island of Perium into two channels, a larger on the east, of 11 miles, and a less on the west of one and one-half miles, and forking at the latter into two branches, the one of which, forming the Gulf of Akaba, penetrates north by east into Arabia for about 100 miles, with an average breadth of about 15 miles; while the other, forming the Gulf of Suez, follows the general direction of the sea, and penetrates between Arabia and Egypt for about 200 miles, with an average breadth of about 20 miles. In the fork between these two branches is the celebrated Mount Sinai, or Jebel Musa (Mount of Moses). To the biblical student the Red Sea possesses considerable interest, from the account of its miraculous passage by the children of Israel when journeying from Egypt. The place at which they crossed the sea was the Gulf of Suez at its northern extremity, but opinions differ as to the exact point of transit, some maintaining that it was in the neighborhood of the town of Suez, and others that it was about 18 miles farther south, at the mouth of the Wady Tuarik. The marine temperature ranges from 70° to 94° F.

The climate is tropical and depressing; both shores of the Red Sea east and west consist generally of a low tract, mostly sandy, though sometimes swampy, varying in width from 10 to 30 miles, and suddenly terminated by the abutments of a lofty table-land of 3,000 feet to 6,000 feet high. The Red Sea may thus be considered as occupying the bottom of an immense longitudinal valley, which probably at one time extended between the table-lands without interruption, but has since been partially filled

up by coral-workings, which, extending in parallel lines at a short distance from either coast, have subdivided the sea into three different channels, and have also studded its shores with numerous small islands. In the main channel the depth reaches in one place 1,200 fathoms, but diminishes toward the extremities, where the depth in general does not exceed from 40 to 50 fathoms; the mean depth may be taken at 375 fathoms.

In the Gulf of Suez, which in earlier times is supposed to have extended considerably farther north, this depth gradually decreases to 30 fathoms, and still continues to shoal, till at the harbor of Suez it amounts to only three fathoms; in the Gulf of Akaba, on the contrary, the depth of the main channel is fully maintained, and in some places even exceeded. The currents of the Red Sea are the result of prevailing winds. These winds, whether proceeding either directly north or south, affect only the main body of the sea, and leave a considerable belt along the coasts subject to alternations of land and sea breezes, and not unfrequently to sudden squalls. The chief dangers to navigation arise from the number of shallow reefs, of the presence of which no intimation is given, as the sea never breaks upon them. This absence of breakers is accounted for by the porous nature of the coral, which offers so little resistance that the sea diffuses through it without commotion, as if it were passing through a sieve. The principal harbors of the Red Sea are, in the African Coast, Suez, Kosseir, Suakin and Massowa; and on the Arabian Coast, Jedda (the port of Mecca), Hodeida and Mocha. The trade from shore to shore is not of much importance, consisting chiefly of the transport of pilgrims and some grain from Egypt; but the trade up and down the sea, between Europe and the East Indies, has become very large since the construction of the great ship canal across the Isthmus of Suez.

A telegraphic cable enters the Red Sea at Suez, passes down to Kosseir on its western shore, thence to Suakin on the same side, about lat. 19° 10' N., and then proceeds in a south-southeastern direction close to the island of Perim, and out into the Indian Ocean by the Strait of Bab-el-Mandeb, and arrives at Aden (q.v.).

RED SHIRTS, the name given to an organization in North Carolina, whose object was to establish and maintain white supremacy in that State and keep the negroes under. It flourished in the reconstruction period after the Civil War. The members wore red shirts.

RED-SHOULDERED HAWK, a large American buzzard-hawk (*Buteo lineatus*), known popularly as one of the hen-hawks (q.v.) and common over most of North America; but western examples differ from the eastern ones and are called the red-bellied hawk (variety *elegans*). It is most numerous south of the Great Lakes in winter, by reason of the accession of northern migrants. It is of large size and distinguished by the rufous tinge of the head, neck and shoulders, and plumage generally, the breast with shaft-streaks of blackish and the tail clear brownish-black, crossed with six sharply defined narrow bands of white. The young are darker and more obscurely marked. The habits of this bird are much

like those of its congeners, the red-tail and broadwing. They may be seen at all seasons "sweeping in graceful curves over the country, rising and falling in spirals, unless after noting prey, when they sometimes dart down hundreds of yards in a very few seconds. Although they feed much on birds and rabbits and are frequent visitors to the farmyard, they seem to have a special predilection for squirrels." They make their nests of sticks in the tops of tall trees and very early in the spring four or five large, globular, heavy blotched eggs are laid. Consult Fisher, 'Hawks and Owls of the United States' (1893).

RED SNAPPER, a fish. See **SNAPPER**.

RED SNOW, the color of which is caused by minute organisms, vegetable or animal. Aristotle hinted at its existence; Saussure in 1760 discovered it on the Saint Bernard and Captain Ross in 1819 brought specimens from the Arctic regions. He had found eight miles of cliffs, 600 feet high, colored by it, in many places to the depth of 12 feet, where the rock was reached. Captain Parry and other Arctic explorers have since met with it abundantly.

RED SPIDER, a small, scarlet web-spinning mite (*Tetranychus telarius*), which damage the leaves of plants in greenhouses. They should be killed off by a kerosene emulsion spray.

RED SORREL. See **HIBISCUS**.

RED STONE, Old Fort, a Pennsylvania structure which figured in the struggle between the French and English for mastery in the Ohio region. It was first a storehouse of the Ohio Company, was a rendezvous for the English when they gathered to advance against the French in 1754 and was burned by the French later in the conflict. At its ruins the leaders of the Whisky Insurrection held a meeting in August 1794 to plan opposition to the Whisky tax.

RED SUNSETS, brilliant phenomena which attracted attention in North America and other parts of the globe in the autumn of 1883 and for several succeeding months. A vivid red glow suffused the entire western sky, remaining for upward of an hour, when it would slowly fade away. This strange sight was first noticed in India, where, it is said, the sun assumed a distinct greenish tinge on nearing the horizon. In striving to account for these strange manifestations a number of solutions were offered, but the theory that met with greatest acceptance was that they emanated from volcanic dust and gaseous matter vomited by Krakatoa, in Sunda Straits. Calculations demonstrated the fact that the manifestations of the red glow coincided with the course which such vapors would take on being wafted away by winds.

RED TAPE, a term applied to unnecessary routine and formality in official affairs. It is derived from the fact that official documents were bound together by red ribbons or tapes. Dickens in 'Little Dorrit,' and Mark Twain, in one of his humorous sketches, have illustrated the working of red tape.

RED WATER, (1) a disease of cattle. See **RINDERPEST**. (2) A marine worm of flagellate protozoa, class *Mastigophora*, order *Dino-*

flagellata, infecting harbor waters, destroying fish and mollusks. Varies in color from yellow to reddish brown and is so called as it turns the water red when present.

RED WING, Minn., city, county-seat of Goodhue County, on the Mississippi River, at the head of Lake Pepin, and on the Chicago, Great Western, the Chicago, Milwaukee and Saint Paul and the Chicago and Northwestern railroads, about 40 miles southeast of Saint Paul. It was settled in 1853, incorporated in 1854 and chartered in 1864. It is in a productive agricultural region in which are deposits of fire-clay. Red Wing is the commercial and industrial centre for a large part of Goodhue and Dakota counties. The chief manufacturing establishments are sewer-pipe works which employ about 450 persons; furniture factories, about 250 employees; stoneware works, 120; other manufactories, with about 130 employees. The prominent public buildings are the churches, schools and several business blocks. The educational institutions are a State training school, Red Wing Seminary, Hague Synod Theological School, Lutheran Ladies' Seminary, high school, public and parish schools, a public library, and private school libraries. There are two hospitals. The three banks have a combined capital and surplus of \$730,000. The government is vested in a mayor and a council of nine members, elected biennially. Pop. 9,048.

REDAN, a fortified work having two faces forming a salient angle in the direction from which an attack may be expected. It is open at the gorge. A double redan has a re-entering angle for mutual defense. The redan is the simplest field work, and is used for defending the avenues of approach to a village, bridge or defile. In front of another field work, it is called a *flèche*. When flanks are added to the faces, the work becomes a detached bastion or lunette. The redan at Sebastopol in the Crimean War was the scene of stubborn conflict between the Russians and the English.

REDBIRD. See **CARDINAL GROSBEAK**.

REDBREAST, or **ROBIN REDBREAST**, a familiar European warbler (*Erythacus rubecula*), which by its familiar habits has endeared itself to children, and has caused it to be protected and welcomed more than any other bird. The red breast of the male is the distinguishing feature of the species, but the females have duller colors. In Great Britain the redbreast is a permanent resident, but in more northern countries it is migratory, flying southward in winter. It also occurs in Asia Minor and in North Africa. The nest is made of moss and leaves, and is lined internally with feathers. The eggs number five or six, and are white, spotted with pale brown.

These birds, in winter especially, become very bold and confident in habits, approaching doors and windows without fear, and soon learning even to know the hand which deals out crumbs and scraps of food to them during the inclement season. On the approach of the milder spring the redbreast returns to its native haunts and wilder state. During the breeding season these birds are very pugnacious and they may attack and drive away all the smaller birds from the vicinity of the nest. The food in spring consists chiefly of insects, while in autumn fruits and seeds constitute the dietary.

The song is sweet, but not specially remarkable, and continues during spring, summer and autumn, often in rainy weather. In Germany it is termed *Thomas Gierdet*; and in Norway, *Peter Ronsmad*.

REDBUCK. See **DIUKER-BOK**.

REDBUD, a tree. See **CERCIS**.

REDCAP, a variety of Hamburg fowls. See **POULTRY**.

REDDING, Cal., city, county-seat of Shasta County, on the Sacramento River and on the Southern Pacific Railroad, about 172 miles north of Sacramento. It is in a mining and lumbering region, in which there are some excellent farms in the fertile valleys. The chief industrial establishments are lumber mills, machine shops, foundries and tool shops. The shipment trade is chiefly in lumber and minerals. It has a well-built courthouse and a sanatorium. Pop. 3,090.

REDDLE, a red ochre or red chalk occurring in Arkansas but not yet utilized.

REDEMPTION, in *Christian theology*, the liberation of sinners from the penalties of the violated divine law; it is effected through the expiating vicarious sacrifice of Christ upon the cross. *In law*, the freeing of an estate from mortgage, or the taking back of mortgaged property upon fulfilling the terms or conditions on which it was conveyed to the mortgagee. See **EQUITY OF REDEMPTION**.

REDEMPTIONERS, or **INDENTURED SERVANTS**, emigrants to the American colonies who sold their services to planters or others for a term of years—four, five or seven, according to the contract—after the completion of which they acquired their liberty with a grant of land. There were redemptioners in the first colony founded in Virginia; the system was introduced in Massachusetts in 1631 and later in Maryland, New York, Connecticut and Pennsylvania. With these indentured servants were brought in many persons who came not of their free will but were kidnapped and held in servitude. See **VILLEINS**.

REDEMPTIONISTS. See **TRINITARIAN**.

REDEMPITORISTINE NUNS, or **ORDER OF THE MOST HOLY REDEEMER**, a religious order of women in the Roman Catholic Church, founded in 1732 by Saint Alfonso de Liguori. They are strictly cloistered, leading the contemplative life, and by their prayers assisting the missionary priests of the order of Redemptorists (q.v.); they are subject to the jurisdiction of the ordinary of their place of residence.

REDEMPITORISTS, members of the Congregation of the Most Holy Redeemer, an institute of missionary priests in the Roman Catholic Church, founded in 1732 by Saint Alfonso de Liguori; in some countries they are known as Liguorians. The institute received the approval of Benedict XIV in 1749. The members, in addition to the three perpetual vows of poverty, chastity and obedience common to all monastic and semi-monastic bodies, bind themselves by a vow of perseverance in the institute until death; by their vow of poverty they are bound to refuse all church benefices, offices and dignities outside of their congregation. Their main occupation is the apos-

olic ministry in conducting "retreats" and "missions" to all classes, with preference for such as are most neglected or who come least under the ordinary ministrations of the church. The Congregation has establishments in various countries of continental Europe and many in the British isles. Their first house in the United States was founded in 1832 at Detroit; they have now houses in many of the principal cities.

REDEYE, the name of two or more common fresh-water fishes: (1) the rockbass or goggle-eye (*Ambloplites rupestris*) (see BASS); (2) in England the rudd, a reddish roach-like fish (*Leuciscus erythrophthalmus*), sometimes two pounds in weight, and highly esteemed by anglers both in Great Britain and on the Continent.

REDFIELD, Edward Willis, American artist: b. Bridgeville, Del., 1868. After early training at the Pennsylvania Academy of Arts, he studied under Fleury and Bonguereau in Paris. In 1896 he won the gold medal of the Art Club of Philadelphia, the first of a long list of medals and awards that his paintings received. Excelling in landscape painting, his inspiration largely drawn from his home surroundings in Delaware, he is represented in the leading art collections and museums of the country, in the Luxembourg (Paris), in the Honolulu museum and in the National Gallery, Buenos Aires. In 1904 he was elected a member of the National Academy.

REDFIELD, Isaac Fletcher, American jurist: b. Wethersfield, Vt., 10 April 1804; d. Charlestown, Mass., 23 March 1876. He was graduated from Dartmouth College in 1825, admitted to the bar and engaged in law practice. He was attorney-general for Orleans County, Vt., in 1832-35, judge of the Vermont supreme court in 1835-52, chief justice in 1852-60, and in 1857-61 occupied the chair of jurisprudence at Dartmouth. He removed to Boston in 1861, and in 1867-69 was special counsel in Europe for the United States. He was editor for New England of the 'American Law Register' and published 'Law of Railways' (1857); 'Law of Wills' (1864-70); 'Leading American Railway Cases' (1870), etc.

REDFIELD, William Charles, American scientist: b. Middletown, Conn., 25 March 1789; d. New York, 12 Feb. 1857. In 1803 he was apprenticed to a mechanic at Upper Middletown (now Cromwell), in 1811 set up for himself at Middletown as a mechanic and small merchant, and in 1821 began his study of the subject of Atlantic gales by observations of the region in eastern Connecticut and western Massachusetts devastated by the storm of 3 September, long known as the "great September gale." By his investigation of the course and direction of prostrated objects, he became convinced that the storm was a progressive whirlwind. The perfecting of his theory of storms became his chief object. In 1831 he began the publication in the *American Journal of Science* of a series of articles on the laws of storms; and in 1834, in an article in the same journal on 'Hurricanes of the West Indies' gave a complete synopsis of the main points of his theory as developed by a more extensive analysis of observed phenomena. His views, known as the 'rotary theory of storms,' were accepted after

some slight opposition; and Redfield, by his explanation of the mechanism of extended hurricanes, became one of the principal contributors to a scientific knowledge of the earth's atmosphere. He wrote also on geography and geology. As a naval engineer he devised the system of "safety barges," by which passenger service via the Hudson between New York and Albany was conducted by means of a passenger boat drawn by two steamers at such a distance as to avoid danger of explosions, the frequent occurrence of which had caused general terror. Thus originated the idea of tow-boats for the conveyance of freight. Redfield was also prominently interested in railway construction. A list of his published papers, from 1829 to 1857, includes 62 titles.

REDFIELD, William Cox, American Cabinet officer: b. Albany, N. Y., 18 June 1858. He engaged in the manufacture of machinery, became president of J. H. Williams and Company in 1905, of the Sirocco Engineering Company in 1907, and was vice-president of the American Blower Company in 1909-13. He served in Congress in 1911-13, and on 4 March 1913 became Secretary of Commerce in the Cabinet of President Wilson. He wrote 'The New Industrial Day' (1912).

REDFIELD, S. Dak., city, county-seat of Spink County, on the Chicago, Milwaukee and Saint Paul and the Chicago and Northwestern railroads, about 35 miles south of Aberdeen. It is an agricultural and stock-raising region. It has a State Institution for the Feeble-Minded and the Redfield College, opened in 1887 under the auspices of the Congregationalists. Pop. 1,431.

REDFIN. See SHINER.

REDFISH, the name of several fishes notable for their color: (1) In Alaska, the salmon more familiarly known by its name "blueback" in the Columbia River Valley; also called redfish about the lakes of northern Idaho. (2) On the California coast, a gaudily tinted wrasse (*Pimelometopon plucheri*), related to the eastern tautog, which reaches a weight of 12 or 15 pounds, and is taken in large numbers in the kelp offshore with hook and line. The Chinese salt and dry them. (3) The rose-fish (q.v.) of the Atlantic Coast. (4) The red drum. See DRUMFISH.

REDGAUNTLET, *réd-gānt'lēt*, a novel by Sir Walter Scott, published in 1824. Sir Alberick Redgauntlet, ardently espousing the cause of the Young Pretender in 1745, pays for his enthusiasm with his life. His widow, ascribing her bereavement to the politics of the Redgauntlets, desires to rear her children in allegiance to the reigning dynasty. Her efforts prove ineffectual and the tale is concerned with the plots to enthrone the Chevalier, into which young Redgauntlet is hurried by his uncle, an ardent Jacobite. Though showing haste, the story does not flag in interest, and even the minor characters—notably Peter Peebles, the crazy litigant, Wandering Willie, the vagabond fiddler, and Nanty Ewart, the smuggler—are living and individual.

REDGRAVE, Richard, English painter: b. Pimlico, London, 30 April 1804; d. London, 14 Dec. 1888. After studying at the Academy, he was elected an A.R.A. in 1840, an R.A. in

1851. From 1847 he took a prominent part in art instruction, and in 1857 was appointed inspector-general of art schools, which office, with that of surveyor of the royal pictures, he resigned in 1880. His principal pictures include 'Gulliver on the Farmer's Table' (1837); 'The Daughter of the Reduced Gentleman' (1840); 'The Return of Olivia'; and 'Country Cousins.' He wrote with his brother, 'A Century of English Painters' (1866), and edited several valuable catalogues.

REDHEAD, a duck (*Aythya americana*), related to the pochard and canvas-back (qq.v.). From the latter the redhead may be readily distinguished by its much shorter, broader, more strongly hooked bill, and brighter chestnut head, though it is frequently sold to the uninitiated as the more expensive canvas-back, to which it is little inferior in flavor. It is found in North America generally, breeds from the northern tier of States to high latitudes, and winters in Chesapeake Bay and southward. The nest is built of reeds, etc., with a lining of down, and either on the ground or on a platform of reeds in the water; the seven or eight eggs are buff-colored and unmarked. Eastwardly this is one of the commonest species of ducks and congregates in great numbers in the sounds and estuaries of the Atlantic Coast, consorting with canvas-backs, scaups and other species of generally similar habits. It feeds on various aquatic animals, but more particularly on water celery and other aquatic plants. In the interior about the Great Lakes and elsewhere, these birds usually appear in flocks for a short time during the migrations and are said to visit the woods for the purpose of feeding on acorns and other mast like the wood-duck. The redhead is perhaps the best known and generally appreciated by gunners of all our ducks, but there is nothing especially distinctive of the method of its pursuit. Consult Grinnell, 'American Duck Shooting' (1901); Job, 'Among the Waterfowl' (1902).

REDING, Aloys von, Swiss patriot: b. Schwyz, Switzerland, 6 March 1765; d. there, 5 Feb. 1818. He became captain-general of his native canton in 1788, and defeated the French republicans at Morgarten Pass in 1798. In 1802 he founded a league in the eastern part of Switzerland with the purpose of re-establishing the old federal constitution, but was thwarted by French interference. In 1803 and in 1809 he was elected chief magistrate of Schwyz.

REDISCOUNTING. To foreigners it has always been a subject of wonderment that rediscounting remained in American banking history a branch of financial service availed of little or not at all. Rediscounting has even been looked upon by American bank authorities askance as a "bad" practice and an evidence of weakness on the part of those establishments who had resort to it. What little work in this branch of the financial exchange business has been done was largely confined to country banks, chiefly in the southern States, who have had resort to the system to a small extent, rediscounting with their depository banks in the large cities as an accommodation. But of the total of loans and discounts the rediscounts have figured as a small item only. In Europe, on the other hand, rediscounting constitutes a very large proportion of the great banking

business. The Bank of France at Paris and the Reichsbank at Berlin transact a great volume of business in the rediscounting department, and all the great central banks of Europe find it forms a most important branch of their service. It is generally asserted that the main reason for non-usage of this form of exchange in our commercial life on a larger scale is, that the favored commercial instrument has been the single-name promissory note, just as the bill of exchange has always been the European standby. The consequence has been that, upon its being discounted by the bank, the promissory note has lain as a "dead asset" in the safety vault, as a commodity not capable of being converted into cash until the arrival of date of maturity. The great advantage of the bill of exchange or "acceptance," as in such general use in Europe, is evident in its commercial course. The bill, once drawn by a customer and accepted by his bank, acquires the value of an instrument salable anywhere—it is freely discounted in open market and passes from merchant to merchant or bank to bank, accumulating fresh endorsements at each transaction until it at last reaches the counter of one of the central banks. Here it is appreciated as accommodating the banking business in the voluminous collecting and transference of funds as well as a source of cash supply for the general class of banks. A fundamental obstacle to the general use of a rediscounting system has, of course, been the fact that here we have had no central bank, the great rediscounting factor in European finance. The National Bank Law has not permitted national banks to accept time drafts and the Federal Reserve Act failed to give relief here except for bills based upon foreign trade. But the Federal Reserve Act now enables the reserve bank's members to handle commercial paper and the rediscount system's future is brighter in the United States, and a dozen regional banks in different sections of the country are enabled to pool and convert some of their assets into cash by rediscounting good commercial paper as defined under the act. Now, the strength of the popularity in European banking concerns of rediscounting is the fact that the rediscounting makes the paper a surer asset and the more endorsements it receives the more the security is enhanced, except that each lapse of time makes the note more and more of a temporary security. All bankers acceptances are so liquid as to be a desirable investment of private bankers.

REDLANDS, rēd'landz, Cal., city in San Bernardino County; on the Atchison, Topeka and Santa Fé and the Southern Pacific railroads, about 68 miles east of Los Angeles. It was settled in 1881 and in 1888 was incorporated. It is on the foothills of the San Bernardino Mountains, 1,360 feet above sea-level, in a region famous for its scenic beauty. It is in a fruit section noted for its oranges. It is the largest orange shipping centre in the world. Fire-clay is found in the vicinity. The principal manufacturers are clay and lumber products; and the trade is chiefly in oranges, raisins and other fruits, wheat, barley, brick, lumber and building stone. It has high school, public and parish schools, and the A. K. Smiley Library, University of Redland. Eight parks,

among them Smiley Heights, add to the attractions of the city. The government is vested in a board of trustees. They hold office four years. Pop. 13,000 (government estimate).

REDLEG, one of the best known of Old World partridges (*Caccabis rufa*), which is especially numerous in France, where it is the principal object of sport in the autumn. It has been introduced into England, but is not much liked because slow to fly, running speedily before the dog and so puzzling both the dog and the gunner trained to the different behavior of the British gray partridge. Several other species of the genus share the name, as the Barbary partridge (*C. petrosa*) of North Africa, the chukar (*C. chukar*) of India, etc. See **PARTRIDGE**.

REDLICH, rät'lich, Joseph, Austrian author and professor of law: b. Göding, Mähren, 18 June 1869. He was educated at Vienna, Leipzig and Tübingen, and from 1906 was a member of the faculty at the University of Vienna. He lectured at Harvard in 1910, and was in the United States in 1914 in connection with the Carnegie Foundation. He has written 'Englische Lokalverwaltung' (1901; English trans. 1903); 'Recht und Technik des Englischer Parlamentarismus' (1905; English trans. 1908); 'The Common Law and the Case Method in American University Law Schools' (1914), etc.

REDMOND, rēd'mōnd, John Edward, Irish political leader: b. Dublin, 1851; d. March 1918. He was educated at Trinity College, Dublin, studied law and was admitted to the bar. In 1876 he was elected a member of the House of Commons from New Ross, and later held a position in the vote office. From 1885 to 1891 he sat for North Wexford and from 1891 to his death was member for Waterford. In the House he became a "whip" for the Irish party, and was one of the most active supporters of Parnell in his organization of the Irish Nationalist party. He made several trips to the United States and Canada in behalf of the Nationalists. When the party was divided over the question of the continuance of Parnell's leadership, he supported Parnell. In 1900, when the factions were united, he was made the leader of the united party, which he effectively organized. When the Liberals returned to power in 1906, Redmond's position became one of supreme importance to Ireland and for the following eight years he ably led the movement having for object a measure of self-government for Ireland. His final triumph came when the Home Rule Bill was passed in 1914. On the outbreak of the war with Germany, Redmond, assuming to speak for all Ireland, pledged her support without condition in the war. Meanwhile, Redmond and his party had alienated the support of the younger generation of Irishmen, who disliked the machine methods of the Nationalists at the elections. However, the party and Redmond had grown old during the strenuous years in which they fought for an equitable settlement of the land question and they were not receptive of the new ideas and ideals of nationality which had permeated the younger generation through the work of the Gaelic League and similar organizations. The Insurrection of Easter week 1916 showed to what a point

cleavage had come between Redmond, his party and young Ireland. The stern methods with which the insurrection was suppressed drew all Ireland (Protestant Ulster excepted) together in opposition to the hidebound methods of a leader and party who had become impotent. At by-elections in 1916 and 1917 members of the Sinn Fein or revolutionary party defeated Redmond's candidates and he saw nothing ahead but the breaking up of the old political machine which had outlasted its usefulness. It is believed his end was hastened by the trend of events in Ireland. Redmond was a skilled parliamentarian and an eloquent and forceful orator. He published 'Historical and Political Addresses' (1898), 'Ireland and the War' (1915).

REDONDO BEACH, Cal., city in Los Angeles County, on the Pacific Coast, 18 miles southwest of Los Angeles, on the Atchison, Topeka and Santa Fé Railroad. It is a pleasure resort with ample amusement facilities; and is also important as a shipping point. The city is growing rapidly. Pop. 2,935.

REDONDA (rā-dōn'da) ISLAND, West Indies, one of the Leeward group, situated between Nevis and Montserrat. Iron and alumina mines constitute its economic importance. It is a dependency of Antigua, and with Barbuda, another dependency, makes an area of 62 square miles. The total population of the three islands is about 35,000.

REDOUBT, Alaska, active volcano in the Aleutian Range, near the west coast of Cook's Inlet. Its altitude is 11,270 feet, and it was active in 1903.

REDOWA, rēd'ō-a, the name of a Bohemian dance introduced into England about 1846. The dance resembles the Polish mazurka. It was introduced into one of Meyerbeer's operas in 1849.

REDPATH, James, journalist: b. Berwick-on-Tweed, England, 14 Aug. 1833; d. New York, 10 Feb. 1891. He emigrated to Detroit, Mich., in 1848, and in 1852 removed to New York and became connected with the *Tribune*. In 1855 he went to Kansas and took part in the Free-Soil movement which he described for northern papers. Being already a confirmed anti-slavery advocate he traveled in the South for personal investigation of slavery conditions. With others he then undertook a scheme of colonization in Haiti and during his visits to the island was appointed by President Giffard commissioner of emigration in the United States. The breaking out of the Civil War put an end to his plans, and he entered the field as war correspondent principally attached to the armies of Generals Sherman and Thomas. At the close of the war he became superintendent of education in Charleston, S. C., reorganized its school system, and established colored schools and the Colored Orphan Asylum. In 1868 he established the Lyceum Bureau in Boston which arranged for the public appearance of lecturers and readers, which business was afterward purchased by Maj. J. B. Pond (q.v.). Resuming editorial work on the *Tribune*, he went to Ireland to report the famine of 1879-80. There he became interested in the Home Rule movement and devoted several years to its interests. In 1886 he became

attached to the staff of *The North American Review*. He assisted Jefferson Davis in preparing his history of the Southern Confederacy, and wrote, among other works, 'The Roving Editor, or Talks with Slaves in the Southern States' (1859); 'The Public Life of Captain John Brown' (1860); and 'Talks About Ireland' (1881).

REDPOLL, a small linnet-like finch of the far northern regions, two to three species of which visit northern Europe, Canada, and the northern United States in winter. The males have the head and neck beautifully rose-red in hue.

REDROOT. See **CEANOTHUS**.

REDS OF THE MIDI, The. The first book written in modern Provençal to be published in English was 'The Reds of the Midi' ('Les Rouges du Midi,' 1896). In a Prologue, Félix Gras gives a charming picture of his own boyhood and of his juvenile admiration for the Napoleonic veteran Pascal. Then he introduces us to the little company at the shoemaker's shop where in the evenings old Pascal was wont to tell stories of his campaigns from the Pyramids to Moscow to a little company of whom the boy Félix was not the least eager listener. 'The Reds of the Midi' is based in part on what Gras learned from his grandfather and from Pascal who is made to tell here of the wanton feudal oppression at which his boyhood revolted, of the perils that beset his youth, of his enlistment at Avignon in the famous Marseilles Battalion, the 516 who gave to France its battle song, and, on the memorable 10 Aug. 1792, led the attack on the 'King's Castle,' the Tuileries. This rising of a people is shown as the simple, brave, honest soldier boy might have seen it, and with great art is made to appear wholly objectively from the peasant's point of view. Notable as fiction, the story has, as the author wrote to William E. Gladstone, also the historical purpose 'to prove . . . that it was the men of the South who were the first to rise up against despotism, and that to them the triumph of the Revolution was due. And to prove also that from them came the first protest against the errors, and the violence and the excesses of the Reign of Terror.' There are graphic glimpses of the September massacres and of the guillotine. The translation by Catherine A. Janvier is of exceptional merit. The story is continued as to several minor characters in 'The Terror' (1898).

BENJAMIN W. WELLS.

REDSHANK, or GAMBET, a large migratory snipe-like sandpiper (*Totanus calidris*) of Europe and Asia, representative of a large group, the American species of which are called willets by gunners; its average length is about 11 or 12 inches; and its popular name is derived from the red color of the legs. The spotted redshank (*T. fuscus*) and the greenshank (*T. glottis*) are allied species.

REDSTART, in the United States a small active migratory warbler of the genus *Setophaga*, especially *S. ruticila* of the eastern part of the country, whose colors are a charming contrast of black and orange-red in the male, the female being more nearly brown and yellow. It has a sharp, exclamatory, but pleasing

spring song, and makes a pretty nest of bark-shreds, etc., in an orchard tree or garden bush. The European redstarts are small brownish birds, closely related to the redbreasts, but distinguished by a bright red tail. They construct nests chiefly among the ivy of ruined buildings, the eggs numbering five or six, and being of a greenish-blue color. The redstarts are active birds, feeding on fruits, seeds, and insects which they pursue on the wing. The song is low, but sweet, and these birds are said to imitate very skilfully the notes of other feathered songsters.

REDTAIL, a common American hen-hawk (q.v.).

REDTOP. See **GRASSES IN THE UNITED STATES**.

REDWAY, Jacques Wardlaw, American geographer: b. Nashville, Tenn., May 1849. He was educated at the University of California and at Munich, Bavaria. He occupied the chair of physical geography and chemistry at the State Normal School of California, was engaged in mining engineering and exploring in California and Arizona in 1870-80, and later pursued geographical investigations in South America, Europe and Asia. He has published 'Manual of Geography' (1887); 'Manual of Physiography' (1900); 'New Basis of Geography' (1901); 'Commercial Geography' (1902), etc.

REDWING. (1) An American blackbird (*Agelaius phoeniceus*) found throughout the United States and wintering south of Virginia. The male is jet black except for the wings which are a bright scarlet with a border of buff color. The nest is made of coarse grass or reeds built in a marsh or swamp. Its call is loud and clear. (2) A European thrush (*Turdus iliacus*), visiting Great Britain and southern Europe in winter, when they flock in the fields in search of insects and worms. The summer is spent in the north of Europe and Asia. The summer song is pleasing, but the winter notes are harsh and unmusical. The head, upper part of the body and tail are a rich brown; the lower part of the body is white with streaks of brown.

REDWOOD, Sir Boverton, English chemist: b. London, 26 April 1846. He was educated at the University College School and accompanied Sir Vivian Majendie on an inspection tour of the petroleum fields of Europe, Canada and the United States. He became a consulting engineer and chemist and was appointed adviser on petroleum to the Admiralty, the Home office, the India office and the Colonial office. He was created a baronet in 1911. He served on the war committees of the board of trade, the ministry of munitions and the Admiralty board of invention and research during the European War. Author of 'Cantor Lectures on Petroleum and its Products' (1886); 'The Transport of Petroleum in Bulk' (1894); 'A Treatise on Petroleum' (2 vols., 1896; 3d ed., 3 vols., 1913); and joint author of 'The Detection and Estimation of Inflammable Gases and Vapors in the Air' (1896); 'Handbook of Petroleum' (1901); 'Petroleum Technologists Handbook' (1915), etc.

REDWOOD, the name of various sorts of wood, as an Indian dyewood, the produce of

Pterocarpus santalinus; the wood of *Laplacea hamatosylon*, the redwood of Jamaica; that of *Pterocarpus dalbergioides*, or Andaman wood; that of *Colubrina ferruginosa*, the redwood of the Bahamas; that of *Soymida febrifuga*, of which the bark is used in India for fevers. In the United States, *Sequoia sempervirens* of the Pacific Coast. See REDWOOD OF CALIFORNIA.

REDWOOD OF CALIFORNIA, the great cypress-like forest tree (*Sequoia sempervirens*) of the Pacific Coast. It is of the same genus with the big trees (*S. gigantea*), botanically described under SEQUOIA; the latter occurs in scattered groups on the west slope of the Sierra Nevada, while the redwood forms dense forests on the west slopes of the Coast Range, where it forms the most important timber resource of the State. The forests were thoroughly studied by the government bureau of forestry in 1902, whose report furnishes the following facts: The redwood is popularly thought to occupy a strip of country 10 to 30 miles wide, from the Oregon line to the Bay of Monterey, but these boundaries do not cover its actual distribution. Two thousand acres of redwood exist in Oregon along the Chetco River. South of the Chetco a continuous redwood belt begins, and increases its width from 10 miles, at Del Norte County, to 18 or 20 miles, and keeps on unbroken to southern Humboldt County. Here is a break, but in Mendocino County the belt becomes dense again, and widens out to 35 miles. South of that county the tree grows in isolated patches as far south as the Santa Lucia Mountains.

The climate and topography that have brought about this limited distribution of the redwood deserve attention. North and south along the coast, in nearly parallel ridges, lie the mountains of the Coast Range, steep and rising to altitudes of 1,000 to 2,000 feet. A few large rivers and many smaller streams cut through them to enter the sea, and along their courses in places are broad bottom lands and gentle slopes. West of the Coast Range the climate is even and moderate, with a range from just below freezing to 80° F., and a yearly average of from 50° to 60°. Snow lies on the tops of only the highest ridges. Thirty to 60 inches of rain falls in the autumn and winter, and in the summer sea fog bathes the coast. But east of the mountains, less than 50 miles from the sea, lie hot interior valleys, never visited by the fog, parched and rainless in the summer, and wet only occasionally by the winter rains—conditions too unfavorable to permit the growth of the redwood. The forest may be considered in two types—the "slope" and the "flat." The common type is the "slope"—that is, the growth on the steep sides of the Coast Range, which is a mixture of redwood, red fir, tanbark oak and white fir, with an occasional madroña or hemlock. As the slopes become moderate, the altitude lower, the soil deeper and the water supply better, the redwood steadily gains on the other kinds and the forest becomes denser, until on the rich flats and in the gulches the second type is developed; on the best redwood "flats" no other tree grows.

The redwood grows to a greater height than any other American tree, but in girth and in age it is exceeded by the big trees of the

Sierras. On the slopes 225 feet is about the maximum height and 10 feet its greatest diameter, while on the flats, under better conditions, it grows to be 350 feet high, with a diameter of 20 feet, and occasional giants exceed this. Most of the redwoods cut are from 400 to 800 years old. After the tree has passed the age of 500 years it usually begins to die down from the top and to fall off in growth. The oldest tree scientifically examined began life 531 A. D. The tree, when normal, has a straight, slightly tapered bole, clear for more than 100 feet, and a crown of horizontal branches that may occupy from a third to a half of its total length. The roots strike downward at a sharp angle, and are so large and so numerous as to form a compact mass of wood, in shape like an inverted funnel. The bark of the tree offers such a remarkable resistance to fire that except under great heat it is not combustible. It is of a reddish-gray color, fibrous in texture, and gives to full-grown trees a fluted appearance. The tree, however, assumes many shapes.

The redwood requires little of the soil except that it be moist, and those trees in a gully or along a creek are larger than their neighbors on the ridges. It is, however, so dependent on moisture of the air that this factor mainly or wholly determines its distribution, and the eastern limits of the forests are determined by the distance inland to which the sea fogs may drift.

The enemies of the redwood are few, and it suffers from them less than other trees. "The wind," remarks Fisher, "can scarcely uproot it, insects seem to do it little harm, and fungi seldom affect it. Even fire, the great enemy of all trees, though it may occasionally kill whole stands of young redwood growth, is unable to penetrate the fireproof sheathing of shaggy bark with which the old trees protect themselves." A large area of redwood forest in Santa Cruz County has been reserved as a national forest-park.

Reproduction.—The redwood forest consists of a mixture of trees of widely varying type, and keeps itself stocked by reproduction under its own shade. Seeds grow up very seldom, the seed itself seeming to have little vitality and the opportunities for its germination being rarely present, because it demands plentiful light. Hence new growth is almost exclusively by suckers, which supported and nourished by full-grown roots and stems, thrive under shade in which seedlings would wither. They thus survive and grow slowly, with little or no sun, until an old tree falls, lets in the light and they shoot up in rings about the stump into strong young trees. In 30 years, under favorable conditions, trees will result 16 inches in diameter and 80 feet high; and it is certain that it will be profitable to hold cut-over redwood lands for future crops. This second-growth timber has not the density and fine quality of the original, but is useful for many purposes, and large quantities have already been utilized.

Quality of the Wood.—Redwood is fitted for many uses. In color it shades from light cherry to dark mahogany; its grain is usually straight, fine and even; its weight is light; its consistency firm, yet soft. It is easily worked, takes a beautiful polish and is the most durable of the coniferous woods of California. It resists decay so well that trees which have lain

500 years in the forest have been sent to the mill and sawed into lumber. It has no resin, and resists fire, a fact which has recommended it as material for house-building, especially in San Francisco. Insects seldom injure it, because of an acid element its lumber contains. In sea water, however, the marine teredo eats off redwood piling as readily as other timber. Redwood is used for all kinds of finishing and construction for shingles, railroad ties, electric-light poles, paving blocks, tanks and pipe staves. As a tie its average life, under heavy traffic, is six to eight years; as shingles it will last as long as 40 years. The chief difficulty in working redwood lies in the seasoning process, to dry it thoroughly being a slow and difficult process.

Lumbering.—The cutting of redwood for market began about 1850, and has steadily increased since with the market demand and growth of means of transportation. Its use is mainly confined to the State, and the greatest demand is from the southern counties. Occasional cargoes are sent across the Pacific, but it is rarely sent East, on account of the expense of transportation. It has never been a business giving extravagant profits. Several hundred thousand acres have already been cut over. A large part of this area has been completely cleared and cultivated or used for pasture but much remains as wild brush, believed to be useless; but it is now known that ordinarily a profitable second growth will arise, so that the anticipated extinction of the tree is no longer to be feared.

Felling one of these enormous trees is an operation requiring great experience and skill on the part of the woodsman, who must cause the vast trunk to fall precisely where he intends it to lie, and must take care that it is not split or broken by the concussion, to prevent which a bed is smoothed and prepared for it. A platform is first erected surrounding the trunk from six to eight feet above the ground. With a long saw in the hands of two men an undercut is made through the trunk, not quite to the centre, and from the opposite side a crosscut is sawed, ending a foot or two above the undercut and leaving a section of solid wood between. When the exact place where the tree is to fall is selected, the choppers ascend the platform and with axes hew out an angular-shaped piece having the undercut as a base. When this cut is made the second or crosscut is wedged till the tree topples over and falls to the ground, the solid section of the trunk, not pierced by the cuts, supporting the tree till the centre of gravity is passed, and then the mighty frame falls on its prepared bed almost intact.

The next operation is performed by the "ringers" and "peelers." Every 12 or 14 feet, as required, a ring is cut around the circumference of the bark, and afterward the peelers with crowbars and wedges "peel" the bark from the prostrate trunk. All of the trees are stripped but surrounded with an immense accumulation of debris of bark and branches, which must be removed before the trunks can be sawed into suitable lengths for conveyance to the mill. The ground is cleared of this debris by fire, precaution being first taken to plug up the "splints" in the trunk with clay so that the fire may not reach the interior of the

tree. A foggy day is chosen and a still one. Fire is started and in a short time the tract is burning with a fierce heat that quickly reduces the piles of bark and brush to ashes, and leaves an unobstructed field for the removal of the solid timber which has been scarcely charred by the intense heat to which it has been subjected.

The trunks as they lie are then sawed into stated lengths, and then follows the arduous task of conveying these enormously heavy sections to the railroad. Temporary skidways are laid down and roads constructed. Chutes down which the logs pass have to be planned, and on these, guided by the skilful woodsmen, the unwieldy logs at last reach their destination. The work is assisted by donkey engines on sleds, which are hauled to the top of the steep banks and into seemingly impossible situations.

The yield of virgin redwoods on the northern flats varies from 125,000 to 150,000 board feet per acre. About Humboldt Bay it was from 50,000 to 75,000 feet per acre; and on slopes like those in Sonoma County, from 20,900 to 30,000 feet. The redwood cut of 1916 was 491,000,000, the largest recorded, being about 35 per cent of the entire lumber cut of the State. The amount of timber got out of a redwood forest is only a small proportion of what the stand contained. At least a quarter of the timber is destroyed in felling and in the burning that follows, and of what remains all the broken and misshapen logs are left on the ground.

Bibliography.—Fisher, 'Report on Redwood,' Bureau of Forestry (Washington 1903); and authorities on California, especially Muir, and on forestry. See FORESTRY.

REED, red, Andrew, English philanthropist: b. London, 27 Nov. 1787; d. there, 25 Feb. 1862. He was educated at Hackney College, London, ordained pastor of the Congregational Chapel at New road, London, in 1811 and remained in this charge until 1861. He visited the United States in 1834 to study educational and religious systems and established in London the Orphan Asylum (1813), Infant Orphan Asylum (1827), Asylum for Idiots (1846), Royal Hospital for Incurables (1855) and an Asylum for Fatherless Children in Croydon. He published 'Visits to the American Churches' (1836); 'Advancement of Religion the Claim of the Times' (1847), etc. Consult 'Memoirs,' edited by his sons (1863).

REED, Sir Charles, English politician and philanthropist, son of Andrew Reed (q.v.): b. near Sonning, Berkshire, 20 June 1819; d. Tottenham, Middlesex, 25 March 1881. He amassed a large fortune in the typefoundry business, took an active interest in the philanthropic works of his father, served in Parliament as member for Hackney in 1868-74 and was re-elected for Saint Ives in 1880. He was president-chairman of the London school board in 1873-81 and in 1874 he was knighted.

REED, Charles Alfred Lee, American surgeon: b. Wolf Lake, Ind., 9 July 1856. He was educated at Miami University, Oxford, Ohio, and studied medicine at the Cincinnati College of Medicine and Surgery. He was professor of gynecology and abdominal surgery at the Cincinnati College of Medicine and Surgery 1882-95; became gynecologist at the Cincinnati

Hospital in 1896, and was president of the American Medical Association in 1900-01. He has published various professional monographs and a 'Text Book of Gynecology' (1900).

REED, Sir Edward James, English naval architect: b. Sheerness, 20 Sept. 1830; d. 30 Nov. 1906. He was educated at the School of Mathematics and Naval Construction in Portsmouth, was at one time connected with Sheerness dockyard, and having become an authority on naval architecture was appointed chief constructor to the navy, for which he designed a number of ironclads and other vessels. He resigned in 1870 on account of his objections to rigged sea-going turret ships which he found to be growing in favor. He sat in Parliament for the Pembroke boroughs 1874-80, for Cardiff in 1880-95 and again 1900-06. In 1886 he was a junior lord of the treasury under Mr. Gladstone. In 1878 he visited Japan on the invitation of the government of that country. He published 'Japan, its History, Traditions and Religions' (1880); 'The Stability of Ships' (1884); 'Modern Ships of War,' with Admiral Simpson (1888); 'Poems' (1902).

REED, Elizabeth Armstrong, American author: b. Winthrop, Me., 16 May 1842. She was married to H. V. Reed in 1860. She was chairman of the Woman's Congress of Philology in Chicago in 1893 and has been a member of several learned societies. She has published 'The Bible Triumphant' (1866); 'Hindu Literature: or the Ancient Books of India' (1891); 'Persian Literature, Ancient and Modern' (1893); 'Primitive Buddhism, its Origin and Teachings' (1896), etc.

REED, George Edward, American educator: b. Brownville, Me., 21 March 1846. He was graduated from Wesleyan University, Middletown, Conn., in 1869 and after studying theology in Boston University entered the New England Southern Conference in 1870. He filled important appointments in the Methodist denomination 1870-89 and in the year last named became president of Dickinson College, Carlisle, Pa.

REED, Hugh T., American military officer: b. Richmond, Ind., 17 Aug. 1850. He was graduated from West Point in 1873 and served chiefly on frontier duty until 1881 when he was appointed inspector-general on the staff of Governor Porter of Indiana. He was retired for disability in 1889. He has published 'A Calendar of the Dakota Nation' (1887); 'Cadet Regulations' (1881); 'Broom Tactics' (1883), etc.

REED, James A., American legislator: b. near Mansfield, Ohio, 9 Nov. 1861. He removed with his parents to Lynn County, Iowa, in 1864, studied at Coe College, Iowa, and was admitted to the bar in 1885. He engaged in practice at Cedar Rapids in 1885-87, then removing to Kansas City, Mo. He was prosecuting attorney of Jackson County, Mo., in 1898-1900, and mayor of Kansas City in 1900-04. He was elected to the United States Senate for the terms beginning 1911 and 1917.

REED, John Oren, American physicist and educator: b. New Castle, Ind., 31 Dec. 1856; d. 22 Jan. 1916. He was graduated at the University of Michigan in 1885, studied at Harvard in 1891-92 and took his Ph.D. at the Uni-

versity of Jena in 1897. He was a member of the faculty at the University of Michigan from 1892, becoming professor of physics and director of the physics laboratory in 1909, and serving as dean of the department of literature, science and the arts from 1907. He was joint author of 'Manual of Physical Measurements' (1902); 'College Physics' (1902); 'High School Physics' (1913).

REED, Joseph, American soldier and statesman: b. Trenton, N. J., 27 Aug. 1741; d. Philadelphia, 5 March 1785. He was graduated from Princeton and spent two years studying law in the Middle Temple, London. He returned to Trenton and took up the practice of law and in 1767 was appointed deputy secretary of New Jersey. In 1774 he was appointed a member of the committee of correspondence for Philadelphia and in 1775 was president of the 2d provincial convention held in Pennsylvania and endeavored to defeat the intention of arming the province. His English connections through his marriage inclined him to a conciliatory view of the English position, though he opposed the principle of Parliamentary taxation. On Washington's appointment to commander-in-chief, Reed became his military secretary. In 1776 he was made adjutant-general, but resigned the next year and refused the office of brigadier-general and also first chief justice of Pennsylvania, preferring to remain Washington's volunteer aide, without rank or pay. In September 1777 he was elected to the Continental Congress but continued with the army and took part in many engagements. In 1778 he was made chairman of a Congressional committee to confer with Washington concerning the management of the ensuing campaign. In December 1778 he was chosen president of the supreme executive council of Pennsylvania and continued in office for three years, during which time he was one of the founders of the University of Pennsylvania and favored the doing away with the proprietary powers of the Penn family. After the English peace commissioners had failed to treat with Congress, attempts were made to bribe Reed together with other high officials. He replied: 'I am not worth purchasing, but such as I am, the king of Great Britain is not rich enough to do it.' In 1780 he was invested with extraordinary powers and was principally successful in quelling the dissatisfaction of the Pennsylvania troops in the army. Consult 'Life' by Henry Reed (1846); Reed, W. B., 'Life and Correspondence' (1847).

REED, Myrtle, American author: b. Chicago, Ill., 27 Sept. 1874; d. 1911. She has published 'Love Letters of a Musician' (1899) which has been widely read; 'Later Love Letters of a Musician' (1900); 'The Spinster Book' (1901); 'Lavender and Old Lace' (1902; new ed., 1907); 'The Master's Violin' (1904); 'A Spinner in the Sun' (1906; new ed., 1909); 'Old Rose and Silver' (1909); 'Master of the Vineyard' (1910; new ed., 1911); 'Threads of Grey and Gold' (posthumously, 1913).

REED, Thomas Brackett, American statesman: b. Portland, Maine, 18 Oct. 1839; d. Washington, D. C., 7 Dec. 1902. He was graduated from Bowdoin College in 1860, winning the first prize in English composition. He then took up the study of law, went to California in 1863,

and was admitted to the bar there. In 1864 he was appointed assistant paymaster in the United States navy and assigned to a gunboat patrolling the Tennessee, Cumberland and Mississippi rivers. On receiving his discharge from the navy, he returned to Portland and established a law practice. His interest in public affairs and ability as a speaker soon made him prominent in the Republican party in Maine and in 1868 he was elected to the lower house of the State legislature, where he served two years. He then entered the State senate and before his term had expired, was elected attorney-general of Maine. From 1874 to 1877 he was city solicitor of Portland and in 1876 was elected to Congress and served there continuously until his resignation in 1899. He first attracted attention in April 1878 by a speech in opposition to a bill to reimburse William and Mary College for losses sustained at the hands of the Federal troops during the war. From that time his readiness in debate, knowledge of parliamentary law and marked executive ability made him a power in the House. In 1885-89, while the Republicans were in the minority, he was their acknowledged leader on the floor and in 1899 was chosen speaker of the House. The Republican majority was small and the business of the House continually delayed by the "filibustering" course of the Democrats. Speaker Reed did not hesitate to enforce strict rulings against such tactics and ordered the clerk to count as present all members actually in the House, whether they answered to the roll-call or not. This aroused the strongest opposition from the Democrats; his conduct was denounced as tyrannous and illegal and the epithet of "Czar" applied to him. His rulings were, however, sustained by the House and later by the decision of the Supreme Court; and in the next Congress, when the Democrats were again in power, he had the satisfaction of seeing his rules adopted by the party that had so violently denounced them. In 1895 and 1897, he was again elected speaker and this time his conduct of the business of the House met with the approval of both parties. As speaker, he had a powerful influence in constructing and guiding legislation, though his name is connected with no single important measure and he raised that office to a position second only to that of the President of the United States. He was a consistent opponent of free silver and was largely instrumental in defeating the free silver bill of 1890. He was also a strong advocate of the policy of protective tariff but was opposed to the administration policy in regard to imperialism and the questions resulting from the Spanish War. To this fact his resignation from Congress in 1899 is sometimes attributed. In 1896 he was a prominent candidate for the presidency and at the Republican National Convention received 84½ votes, being second to McKinley. After 1899 he was engaged in the practice of law in New York. He contributed frequently to the magazines, edited a series of volumes on oratory entitled 'Modern Eloquence,' and published 'Reed's Rules of Parliamentary Procedure.'

REED, Walter, American military surgeon and bacteriologist: b. Harrisonburg, Rockingham County, Va., 1851; d. Washington, D. C.,

23 Nov. 1902. He was graduated from the medical department of the University of Virginia and from the Bellevue Hospital Medical College of New York and was made first lieutenant assistant surgeon, United States army, 26 June 1875. His promotions were captain assistant surgeon, 26 June 1880, and major surgeon, 4 Dec. 1903. In 1890-91, while stationed at Baltimore, he made particular study of bacteriology in the laboratory of Prof. William Welch, of the Johns Hopkins University; and established a laboratory of his own, in which he gave instruction to the student-officers of the Army Medical School. As curator of the Army Medical Museum, at Washington, D. C. (from 1893), he continued his researches and soon became known as one of the leading bacteriologists of the country. His ability was especially displayed in his investigations of the cause and progress of epidemic diseases. In 1898 he was made head of a board for the study of the epidemics of typhoid occurring among the troops collected for the Spanish-American War. After the war he made several voyages to Cuba and was on duty at Havana, studying the diseases of the island and more particularly yellow fever, as a member of a board for its investigation. After a series of brilliant experiments, he was able to announce that yellow fever is conveyed by a certain variety of mosquito (*Stegomyia fasciata*), individuals of which become infected by biting persons ill with the fever and by their bite introduce it into the blood of non-immunes. The United States military government at once proceeded to measures of extermination which banished the fever from Havana, where it had prevailed for three centuries. The Atlantic seaboard of the United States was also thereby freed from constant peril. This achievement must rank among the important triumphs of bacteriological science. Consult Keane, 'Scientific Work and Discoveries of the Late Major Walter Reed' (Senate Doc. 118).

REED, William Bradford, American lawyer: b. Philadelphia, 30 June 1806; d. New York, 18 Feb. 1876. He was graduated from the University of Pennsylvania in 1825 and accompanied Joel R. Poinsett to Mexico as private secretary. Then taking up the practice of law, he became attorney-general of Pennsylvania in 1838. In 1850 he was appointed professor of American history at the University of Pennsylvania and in 1857 became United States Minister to China. The next year he negotiated the treaty with China which regulated commercial relations as well as made more secure the rights obtained by the previous treaty of 1844. Subsequent to his return to America in 1860 he settled in New York and corresponded for the *London Times* besides contributing to *The American Quarterly Review* and the *North American Review*. He engaged in a controversy with George Bancroft, concerning certain statements repeated by the historian to the effect that his grandfather, Joseph Reed, meditated abandoning the American cause and going over to the British. In this controversy Reed wrote 'President Reed of Pennsylvania, a reply to George Bancroft and Others' (1867). Bancroft responded with 'Joseph Reed, an historical Essay' (1867), to which Reed replied with 'A Rejoinder to Mr. Bancroft's Historical Es-

say' (1867). He published 'Life and Correspondence of Joseph Reed' (1847); 'Life of Esther de Berdt' (1853).

REED. (1) *in music*, the sounding part of several instruments, such as the clarinet, bassoon, oboe and bagpipe, so called from its being made from the outer layer of a reed (*Arundo sativa* or *donax*) found in the south of Europe. The name is also applied to the speaking part of the organ, though made of metal. Reeds are generally divided into two kinds—the beating reed, used in the organ, clarinet, etc., requiring to be placed upon a tube to produce a musical sound, and the free reed, used in instruments of the harmonium and concertina kind. (2) *In weaving*, an appurtenance of the loom, consisting of two parallel bars set a few inches apart and furnished with a number of parallel slips or reeds, called dents, between which the warp threads are passed. The reed is set in a swinging frame, called a lathe, lay or batten. In the hand lathe, the bottom of the batten is furnished with a shelf, called the shuttle race, along which the shuttle is driven. The office of the reed is to beat the weft up to the web and the force of the blow determines the compactness of the fabric.

REED, FLUE AND STRINGED INSTRUMENTS. TEMPERAMENT, TUNING AND VOICING OF.

Temperament.—The intervals of the perfect octave are divided naturally into 53 parts or commas, the successive sounds of the diatonic scale being separated by these commas into the following intervals:

C to D	9 commas	9
D to E	8	17
E to F	5	22
F to G	9	31
G to A	8	39
A to B	9	48
B to C	5	53

Nature's arbitrary division of the octave, into intervals of exact dimensions, is not satisfactory, nor does it admit of an exact equalizing; the only possible approach to it being by the method known as the 'even temperament,' which method or principle was discovered and established by John Sebastian Bach, in the early part of the 18th century, who learned that certain intervals would bear being tuned sharp (in excess of) or flat (short of) perfect; the thirds and fourths being tuned sharp and the fifth tuned flat of perfect, thus distributing among all the 12 keys of the octave, the three commas or points by which the major tones exceeded the minor, thus rendering equal the five tones in the diatonic series. Previous to this time, it had been the custom to tune to perfect intervals, those keys having not over three sharps or flats and play in those keys only. The problem to be solved was to so divide the octave into 12 semitones by fixed sounds, that each one of the 12 sounds could be made the key note upon which a properly proportioned diatonic scale could be based, either in the major or minor form, and a melodic or harmonic progression made possible through the whole 24 major and minor scales; so that from any one of these 12 notes a uniform chromatic scale could be constructed, thus making possible modulations of unlimited variety and beauty.

The method then of tempering the notes of keyed instruments consists in arbitrarily adjusting the enharmonic diesis, that is, the dis-

tinction there is naturally between D sharp and E flat, G sharp and A flat, by tuning these notes too sharp for one and too flat for the other of these natural tones or intervals, and by making a similar compromise between the more minute discrepancies of the diatonic scale. Thus while no interval will be exactly true, yet none will be so adjusted as to shock the ear by false intonation, but rather add a color or quality to the tonality of the instrument, which, though harmonious, would otherwise be characterless.

Rule for Tempering Pianos and Organs.—Tune middle C to desired pitch, then tune F—fifth below—sharp of C, until between C and F, there result three beats in five seconds. Next tune A-sharp—fourth above F-sharp of the latter, until there results one beat, each second. Next tune G—fourth below middle C—flat of C, by one beat a second; then tune D—fifth above—flat to G, by three beats in five seconds; A—fourth below—flat to D; E—fifth above—flat to A; B—fourth below—flat to E; F-sharp—fourth below—flat to B; C-sharp—fifth above—flat to F-sharp; G-sharp—fourth below—flat to C-sharp; D-sharp—fifth above—flat to G-sharp, which will make D-sharp as sharp of A-sharp, as the latter is sharp of the first F tuned.

In all the above intervals, the fifths beat three times in five seconds; the fourths beat once a second, or five times in five seconds. All the 12 notes, from F below middle C to first E above, have now been tuned; the temperament has been confined to the smallest possible compass to lessen the liability of errors, and if the first F above middle C is now tuned three beats in five seconds, flat of A-sharp below, it will be a perfect octave to the first F tuned.

Tuning.—The art, principle or act of so adjusting the intonations of keyed musical instruments as to make possible consecutive musical tones agreeable to the ear. The method varies according to the kind or character of the instrument. Where strings are used, as in pianofortes, harps, violins, violas, guitars, zithers, etc., tuning consists in adjusting the tension of the strings by turning the pins or pegs around which the strings are wound. In hand and orchestral wind instruments, a crook or joint is used, sometimes called a slide, because it slides in and out to adjust the length of the column of air in the tube to the point where the desired pitch of the fundamental note is obtained.

In reed organs it depends upon the adjustment of the comparative weight, length and thickness of the reeds, and in pipe organs upon the length of the vibrating column of air in the flue pipes.

In the tuning of strings, the pitch is determined by the size, length and tension of the wire. In reed tuning the desired pitch is obtained by filing or scraping the reed; at the base or fixed end to flatten the tone and at the point or free end to sharpen it.

Organ pipes are tuned according to their construction. The large open flue wood pipes are lowered or flattened in pitch by being lengthened by a sliding cap or by a board fastened to the back, at the top, and is raised or sharpened in pitch by being shortened.

The large open metal flue pipes are tuned by cutting away or adding to the length or

by a slit in the back near the top, making two flaps to be opened or closed as required; closing them lowers the pitch, opening them raises it; the small metal pipes being tuned by the use of a conical horn, with which the tops of the pipes are contracted or expanded, as the pitch is to be lowered or raised respectively. Stopped metal pipes are tuned by a cap, raised or lowered as desired, and reed pipes by adjusting the wire which bears upon the reed, the raising or drawing up of the wire increasing the effective length of the reed and so flattening it and vice-versa. In the tuning of pipe organs, the reed pipes are the last to be tuned, since they are the most liable of all the pipes to become disarranged.

Voicing of Keyed Musical Instruments.—The voicing of organ pipes consists in the adjustment of their various parts, consisting of the mouth, throat, lips, languid and ears, the correct method of treatment having been learned by experience many years ago and of late years demonstrated by mathematical calculations and by the investigations of scientists.

The languid is that flat piece of the pipe which lies horizontally above the upper part of the foot, and it is against this languid the "sheet of wind" is forced from the "wind way" below. Some of the pipes have the languids grooved upon their face, as one method of voicing, and some metal pipes are voiced by bending the ears, which are placed on either side of the mouth. Pipes once voiced at the factory seldom need any alteration.

The voicing of reeds in the common house organ is accomplished by giving the free end of the reed a slight curl or circumflex, and this also causes the reed to speak or sound more promptly and with less pressure of wind.

The voicing of pianos consists in the stabling of the felt of which the hammers are made, by several needles fastened in a handle. The thrusts should be made directly toward the centre of the hammer and not through the top of the felt, from the sides. In the making of hammers, which is done by machinery, one entire set being covered with felt at a time, there is a variation as to hardness in the individual hammers, and voicing is relied upon to lighten up the felt and give a uniform character of tone throughout the entire scale of the piano.

EDWARD QUINCY NORTON,
Author of 'Construction, Tuning and Care of the Pianoforte.'

REED-BIRD. See BOBOLINK.

REED CANARY GRASS, a grass of the genus *Phalaris*. See GRASSES IN THE UNITED STATES.

REEDBUCK. See REITBOKS.

REEDER, Andrew Horatio, American politician, first governor of Kansas Territory: b. Easton, Pa., 6 Aug. 1807; d. there, 5 July 1864. He practised law at Easton and was a prominent Democratic politician when, in 1854, he was appointed by President Pierce the first governor of the newly-formed territory of Kansas. Upon arriving at his post he at once rendered his position difficult by declaring his intention rigidly to put down the violence resulting from the conflict of the two parties respecting slavery. In the election of March 1855 more than three-fourths of the votes cast

were illegal, but the governor issued certificates of election to all claimants whose papers were regular and against whom no protests or official notice of frauds were presented. His action he defended as strictly legal and declared that any other would have been revolutionary, though he confessed to knowledge of the fraudulent voting. He was dismissed from office by the President and he returned to Lawrence to reside and to join forces with the Free-Soil movement. He was nominated by this party as Territorial delegate to Congress. A legislature of the Free-State party formed under the instrument known as the Topeka constitution elected him to the United States Senate in 1856. But the election was refused ratification by Congress. President Lincoln appointed him a brigadier-general at the outbreak of the war, but considerations of age induced him to decline. Consult Spring, 'Kansas' (1885); Robinson, 'The Kansas Conflict' (1892).

REEDFISH, a crossopterygian ganoid fish (*Calamoichthys calabaricus*), which, with the bichir is the only survivor of a group prominent in palæozoic time, which dwells in the sluggish reedy rivers of the Senegal coast of Africa, searching the mud of the bottom for prey.

REEDSBURG, Wis., city in Sauk County, 150 miles northwest of Milwaukee, on Baraboo River and on the Chicago and Northwestern Railroad. It has lumber, dairying and livestock interests, manufactures woolens and flour and is a shipping point for potatoes, apples and other products. Pop. 2,615.

REEF, the part of a sail comprehended between the top or bottom and a row of eyelet holes generally parallel thereto. The object of the reef is to reduce the surface of the sail in proportion to the increase of the wind; for which reason there are several reefs parallel to each other in the superior sails; thus the top-sails of ships are generally furnished with three reefs and sometimes four; and there are always three or four reefs parallel to the foot or bottom of those main-sails and fore-sails which are extended upon booms. When a reef has to be taken in the sail is slightly lowered; the men climb out along the lower boom or yard, which they lean over, with their feet supported by the foot-ropes, fold the loose portion of the sail around the yard and tie them up with the cords inserted in the eyelet-holes. As the operation of reefing is dangerous in stormy weather many ships are now fitted up with a patent apparatus by which sails may be reefed from the deck.

Reef also implies a chain of rocks lying near the surface of the water.

REEL, a revolving contrivance on which fibre, thread, cord, rope, fabric, etc., are wound to form them into hanks or skeins, and for various other purposes. The term is applied in agriculture to a device having radial arms carrying horizontal slats and rotated by gear or pulley connected with the axle of a harvester, for pressing backward and holding the stalks of grain in position for being severed by the knives. In angling, a skeleton barrel attached to the butt of a fishing rod, around which the inner end of the line is wound, and from which it is paid out as the fish runs off with the bait, and is gradually wound in again as his struggles become less violent, bringing him to land or

to the landing net. In baking, a cylinder with radial arms rotating in a heated chamber, carrying pans in which loaves of bread are placed for baking in the reel-oven. In cotton machinery, a machine on which cotton is wound, making hanks of thread. In domestic industry, a spool or bobbin of wood on which cotton, thread, silk, etc., is wound for use in sewing.

Also the name of a lively rustic dance in which the couples sometimes swing or whirl round, and sometimes pass, forming the figure 8. In the United States the Virginia reel was widely popular. Also the music for such dance, generally written in common time, but sometimes in jig time of six quavers to a bar. The Scotch dance known as a reel is executed by two couples, the music for which is generally written in common time of four crotchets in a bar, but sometimes in jig time of six quavers.

REEM, in Scriptural zoology, *Bos primigenius*. In the Authorized Version the influence of the Septuagint has prevailed, and the word is translated "unicorn," but erroneously, as the mention of two horns on one reem (Deut. xxxiii, 17) proves. The word unicorn has disappeared from the Revised Version, wild ox being substituted for it; but in Num. xxiii, 22, the alternative rendering ox-antelope (*Oryx leucoryx*) is given in the margin. The term is still a vernacular name among the Arabs of the Sahara for a gazelle (*Gazella loderi*).

RE-ENTRY, legal term designating the resuming or retaking possession of lands or tenements by the landlord in case of non-payment of rent or public dues. Usually a clause providing for re-entry in case of non-payment is inserted in the lease; and under this the landlord may enforce ejectment either through notification of his wish to re-enter or, if necessary, through process of law.

REES, rēs, Abraham, English Presbyterian clergyman: b. Llanbrynmair, Wales, 1743; d. 9 June 1825. He prepared for the ministry at Hoxton Academy, where in his 19th year he was appointed mathematical tutor to the institution, and soon after resident tutor, in which capacity he continued upward of 22 years. He was pastor to the Presbyterian congregation of Saint Thomas', Southwark, 1768-83, and of a congregation in the Old Jewry from 1783 till his death. In 1776 he undertook a revision and expansion of 'Chambers' Cyclopædia,' which he completed in 1785. The success of this work led him to a new undertaking, similar in its nature, 'The New Cyclopædia,' in 45 volumes (1802-20), republished at Philadelphia in 47 volumes.

REES, John Krom, American educator: b. New York, 27 Oct. 1851; d. there, 9 March 1907. He was graduated from Columbia in 1872 and from the Columbia School of Mines in 1875. He filled the position of assistant professor of mathematics in the Columbia School of Mines 1873-76, and was professor of astronomy in Washington University, Saint Louis, 1876-81. He was director of the observatory and instructor in geodesy and practical astronomy in Columbia 1881-84, and from 1884 professor of astronomy there. He was president of the New York Academy of Sciences in 1894-96, was elected Fellow of the Royal Astronomical Society of London; and in 1901 received

the decoration of Chevalier of the Legion of Honor.

REESE, rēs, Michael, American pioneer: b. Heinsforth, Bavaria, 1816; d. Germany, 2 Aug. 1878. Apprenticed to a tanner, he worked at his trade until he emigrated to the United States, and there after some reverses he established a jewelry business in which he was successful. In 1850 he went to California and began investing in San Francisco real estate. When the Fraser River excitement was at its height, Berri, a Swiss banker, disheartened as to the future of San Francisco, expressed to Reese his desire to part with his holdings. Reese having a firm belief in the coming importance of the city purchased Berri's property and thus laid the foundation of his great wealth. Among his benefactions was his gift to the University of California of the Lieber Library. The Michael Reese Hospital of Chicago, Ill., is his memorial, while his legacies to charities in the aggregate reached half a million dollars.

REEVE, Richard Andrews, Canadian physician: b. Toronto, 1842. He was graduated at Toronto University in 1862 and took his M.D. at Queen's University in 1865. He engaged in practice at Toronto and specialized in the treatment of the eye and ear. In 1867-72 he was assistant surgeon at the Toronto Eye and Ear Infirmary, and subsequently became lecturer on ophthalmology and otology at the Toronto School of Medicine (now Medical Faculty of the University of Toronto). He was dean of the faculty in 1896-1908, when he resigned. He was president of the British Medical Association in 1905, and was then elected a life vice-president.

REEVE, Tapping, American jurist: b. Brook Haven, L. I., October 1744; d. Litchfield, Conn., 13 Dec. 1823. He was graduated from Princeton in 1763 and in 1767-70 was engaged as a tutor there. In 1772 he established a law practice at Litchfield, and during the war served as a recruiting officer and as a member of various committees of safety and defense. In 1784 he opened a law school at Litchfield which became justly famous and for years was without an American rival. He conducted it without assistance until 1795, when he became associated with James Gould, who succeeded him in 1820. He was a judge of the Supreme Court of Connecticut in 1798-1814, served as chief justice for a short time and subsequently served a single term in each the legislature and the council, after which he declined to hold further office. He was a Federalist, a lawyer of high ability and was the originator of the movement to secure to married women the legal right to dispose of their own property. He published 'The Law of Baron and Femme; of Parent and Child; of Guardian and Ward; of Master and Servant,' etc. (1816), republished in numerous editions; and 'A Treatise on the Law of Descent' (1825).

REEVE, a bird. See RUFF.

REEVES, Arthur Middleton, American philologist: b. Cincinnati, Ohio, 7 Oct. 1856; d. in railway accident near Hagerstown, Ind., 25 Feb. 1891. He was graduated at Cornell in 1878. He specialized in the study of languages and after 1879, when he visited Iceland, he devoted much of his time to European travel

and the study of the sagas and ancient manuscripts. With Beamish and Anderson he wrote 'The Norse Discovery of America' (pub. posthumously 1906). Author of 'The Finding of Wineland the Good' (1890; new ed., with biography and correspondence of the author, 1895).

REEVES, revz, Helen Mathers, English novelist: b. Misterton, Somerset, 26 Aug. 1853. In 1876 she was married to Henry Albert Reeves, a London surgeon. 'Comin' Through the Rye,' her first story (1875), was widely popular both in this country and her own, and among her later fictions are 'Cherry Ripe' (1877); 'As He Comes Up the Stair' (1878); 'My Lady Green Sleeves' (1879); 'The Sin of Hagar' (1896); 'Becky' (1900); 'Tally Ho' (1906); 'Pigskin and Petticoat' (1907); 'Love the Thief' (1909). Her style is pleasing and animated and the interest of her novels is well sustained.

REEVES, John Sims, English tenor singer: b. Woolwich, Kent, 26 Sept. 1818; d. Worthing, Sussex, 25 Oct. 1900. He studied music and, in 1832, became organist in the church of North Cray, Kent, and made his first appearance as a singer in 1839 on the Newcastle stage. He first sang in London in 1842, and having studied in Paris and Milan made his first appearance at the La Scala Theatre of the latter city as Egardo in Donizetti's opera, 'Lucia di Lammermoor.' His voice was of wide compass and great beauty — mellow and powerful, capable of the tenderest pathos and of the most stirring martial appeal, but always controlled by genuine artistic feeling and knowledge. He was heard to most advantage in the concert hall and in oratorio parts, and in such pieces as 'Guy Mannering' he displayed considerable histrionic ability. He published 'Life and Recollections' (1888) and 'My Jubilee' (1889).

REFEREE, in law, (1) a person who tries or examines an issue or question of fact sent to him by judicial order. (2) A person authorized by judicial order to take testimony and investigate on a given case. In England, under the Judicature Act of 1873, in the High Court of Justice trial before referees is ordered only on the consent of the parties or in cases in which accounts or documents are complicated and necessitate long investigation or involve local or scientific facts incapable of trial in the usual manner. Assessment of damages and inquiry and report may be ordered in any case. In the United States referees are appointed in bankruptcy cases and often in divorce proceedings, cases in which accounts are complicated and those in which secrecy is desirable.

REFERENCE AND RESEARCH BUREAUS, or SCHOOL RESEARCH BUREAUS, a type of office maintained in connection with the office of superintendent of schools, the functions of which are: (1) to prepare statistical data from current reports to keep the superintendent informed as to the work of each school in the system, the relative standing of the schools and grades in educational accomplishment and the cost of operating the system; (2) to act as a clearing-house of current information, bringing the experience of other systems to the attention of local authorities; and (3) to conduct standard classroom measure-

ments and other research work as will aid the superintendent and his supervisors in their administrative work. The object of such a specially organized bureau is to do this work during the current school term, so that the schools may make immediate use of the findings obtained and that preventive and remedial measures and economies may be put into effect during the same school year in which they are discovered. The most notable example of such a bureau is in Rochester, N. Y.

REFERENDUM, in the United States, the submission of the legislative acts of a representative assembly to the people for acceptance or rejection by popular vote. Under its American application, the referendum means that a specified time must elapse before a law (or, in case of a city, an ordinance) may go into effect, but if, during the period, a reasonable minority of the people should petition for a referendum on the law, it remains inoperative until after the following election, when it is either ratified or rejected by a majority of the popular votes. The period usually allowed before bills may become laws is 60 days and the percentage of voters who must sign a petition to secure a referendum varies from 5 per cent in South Dakota to 10 per cent in North Dakota. In 1906 Oregon amended her law so that the referendum might be invoked not only upon entire laws but also upon individual items or parts of laws. Every measure to be submitted to the people, on demand of initiative or referendum petitions, must be filed not less than four months before the general election. A comprehensive ballot title for each measure is formulated by the attorney-general and a campaign book is prepared by the Secretary of State. The proposed law is printed in full in this book as well as any arguments that may be advanced by the advocates or opponents of the measure, the interested parties paying the exact cost of the paper, and printing required to present these arguments. A copy of this book must be mailed by the Secretary of State to every registered voter in the State eight weeks before the general election, the State bearing the cost of printing the text of the law and postage as a legislative expense. This enables the voter to familiarize himself with the authentic details of the proposition the fate of which he is called upon to determine and allows sufficient time for discussion between individuals and by every variety of organization throughout the State. Under this device the people may kill bad laws and overthrow the work of tools of political bosses who intend to foster their private or political fortunes in the State legislative body; moreover, by a threat of invoking this remedy, much pernicious legislation can be prevented, franchise stealing eliminated and the corrupting lobby rendered unprofitable. On the other hand if the legislature exhibits indifference to public requirements and persistently refuse to enact the necessary legislation, the people have an effective remedy in the initiative (q.v.) and to a considerable extent in the recall (q.v.).

Since the 16th century a form of referendum has existed in some of the cantons of Switzerland. Under the Swiss Constitution all constitutional amendments must be ratified by the electorate before they become law. In

eight cantons an obligatory referendum is in vogue, requiring the submission to the electorate of every law and every expenditure above a fixed maximum, and no demand for such submission to the electors is necessary. Other measures of national importance must be submitted to popular vote if, within 90 days after their publication, the governments of eight cantons or 30,000 votes throughout the republic should demand such submission. While the terms initiative and referendum were almost unknown in American politics prior to 1890, yet an analogy is to be found in colonial days. In the Plymouth colony, even after the towns began to send deputies to their representative legislature, the "whole body of the freemen" appeared at the June court to make laws and repeal such of the laws enacted by the legislature as appeared "prejudicial to the whole." Even in the Massachusetts constitution of 1780 the bill of rights expressly reserved to the voters the right to instruct their representatives in the legislature, and both prior to and after the Revolution this right was freely exercised. Almost from the beginning, with a few exceptions, the State constitutions and amendments thereto have been referred to the voters of the State for ratification or rejection. (See CONVENTIONS, CONSTITUTIONAL). Some of the States have introduced another type of referendum by amending their constitutions so that legislative acts, which relate to specific subjects (such as incurring a State debt or the sale of school lands), must be subjected to popular vote. In a few States, the constitutions of which contained no such authorization, the legislatures attempted to submit to popular vote miscellaneous questions of a perplexing nature, but this practice was checked by court decisions on the ground that such action on the part of representative assemblies was an unwarranted delegation of their law-making powers. In 1901 Illinois enacted a law which might be termed an "advisory initiative," providing that upon petition of 10 per cent of the registered voters a given proposal, such as a "question of public policy," must be submitted to the electorate of the entire State. A similar law has been passed in Delaware and several other States.

The first referendum league in the United States was organized in New Jersey in 1892 but South Dakota was the first State to adopt the optional or facultative referendum, the necessary amendment to the constitution being adopted in 1898. Her example was followed by Oregon (1902), Nevada (1905 and 1912), Montana (1906), Oklahoma (1907), Maine (1908), Missouri (1908), Arkansas (1910), Colorado (1910), Arizona (1911), New Mexico (1911), California (1911), Idaho (1912), Nebraska (1912), Ohio (1912), Washington (1912), Michigan (1908 and 1913), Massachusetts in a limited form (1913), North Dakota (1914), Maryland (1915) and Mississippi (1916). In 1900 Utah and in 1912 Idaho adopted amendments providing for the initiative and referendum, but the legislatures have not passed enabling acts; New Jersey is experimenting with the referendum in cities and in 1916 Minnesota rejected the plan. The Oregon amendment was bitterly attacked by its opponents who took the matter to court, where a minor judge declared the measure unconstitutional and not in accord with the provisions of the Federal Constitution.

Appeal was taken to the Supreme Court of the State which tribunal not only reversed the decision of the lower court, but held that the referendum "does not abolish or destroy the representative form of government or substitute another in its place. The representative character of the government still remains."

In 1897 the Nebraska legislature enacted a law permitting the cities of that State, upon the vote of a majority of their citizens, to adopt direct legislation methods in the conduct of their affairs. In the same year Iowa extended the initiative to all questions of franchise save those of public ownership. Many Western cities have adopted the direct legislation reform, beginning with Seattle, Wash., in 1892, this city being quickly followed by Buckley, Wash., Alameda, Vallejo, San Francisco, Sacramento, Los Angeles, San Diego, Pasadena and many of the smaller cities of California; Portland, Ore., Grand Rapids and Detroit, Mich., Denver, Des Moines, Minneapolis, Nashville and others. Altogether the initiative, referendum and recall are used more or less completely in about 300 municipalities, some under general State laws and some under special charters. See INITIATIVE; RECALL.

REFINING, in *metallurgy*, the last step in the purifying of gold, silver, tin, copper, lead, etc. Gold and silver are commonly mined together, and are sent from the smelters in bullion bars of mixed metal. It is the work of the refinery to part or separate this mixture into pure gold and silver. Both nitric and sulphuric acid are used in parting. In refining iron, the process has been developed on several lines, as converting and puddling. See **METALLURGY**; **ASSAYING**; **GOLD**; **SILVER**, etc.

REFLECTING GALVANOMETER, a most sensitive galvanometer, devised by Sir William Thompson for use in connection with the Atlantic submarine cables. A short needle is rigidly attached to a small concave mirror and suspended by a silk fibre in the centre of a vertical coil of small diameter. This mirror is

adjusted by means of a directing magnet to throw the rays of light (falling on the mirror through a hole having a fine wire stretched upright across it and placed just under the graduated scale opposite the mirror) back on the scale. An image of the wire is thus thrown on the scale, and the slightest motion of the needle and its mirror will produce a much greater motion of this image.

REFLECTION. See **LIGHT**.

REFLECTIONS ON THE REVOLUTION IN FRANCE, published in 1790, remains to-day one of the most interesting and important of the writings of Edmund Burke (1729-97). The immediate object was an answer to a famous sermon which Dr. Price had preached in favor of the Revolution, but it amounts to a very comprehensive indictment of the entire revolutionary movement. Regarding the issue as of unparalleled importance, Burke devoted the greater part of the year to the preparation of the book. The spirit animating him was his dislike of revolution in comparison with the slower and less disrupting processes of reform. As such, the book has been cited (cf. Lord Hugh Cecil's 'Conservatism') as the Bible, primer and textbook of modern British conservatism, as the most distinguished commendation of the principles which dominated the present Conservative party in England, at least up to the outbreak of the World War. The book is a great philippic and jeremiad against the spirit of revolution in general and the French Revolution in particular. It is replete with sound, sober principles on the one hand and warnings and prophecy of disaster on the other. Many of these prophecies were justified by the Napoleonic event, and Burke's wisdom appears in very favorable and dignified light. The 'Reflections' were written with great care and elaboration in Burke's most weighty style, and no one of his writings is more replete with political philosophy and striking aphorism. He discusses such fundamental matters as the use of prejudice, superstition and power as forming valuable assets in government. Some of these passages are famous, such as his diatribe against revolutionary finance or his analysis of the principles of the great bad men like Cromwell; but the most resplendent paragraph in the book is that describing the Dauphines and lamenting the decay of chivalry in the world. John Morley's 'Burke' gives the best short account of the 'Reflections' and their relation to Burke's other writings.

WILLIAM T. BREWSTER.

REFLECTOR, a smooth polished surface by which the rays proceeding from a luminous or heated object are thrown back or diverted in a given direction. The reflecting surface may be either plane or curved. In practice it is often made spherical or parabolic. The former does not bring the rays to a true focus, but is easily formed, and is consequently generally employed where extreme accuracy is not sought for. A mirror is a familiar example of a plane reflector. The reflectors of lighthouses have been very highly developed. (See **LIGHT**; **LIGHTHOUSE**). In telescopes, where a reflector is used the entire instrument has come to be known as a reflector. See **TELESCOPE**.

REFLEX ACTION, a non-voluntary

action affecting a muscular apparatus in response to some kind of sensory stimulus. Such a reaction implies the traversing of the sensory stimulus to some nerve centre or centres in the brain, the medulla, or the spinal cord, and the setting free of a muscular response, general or local, to certain organs of the body, without the participation of willed conscious action, although consciousness of a reflex act performed may precede or accompany the act. Many of these reflexes are extremely intricate, so intricate in fact that certain philosophers have attempted to show that all life-processes are of the type of reflex actions. Many reflex actions, by reason of the fact that their muscular equivalent acts on blood vessels, may increase or decrease glandular activity. This might destroy the ability of the stomach to digest. Dryness of the mouth is frequent as a result of certain forms of unconscious excitement, and many if not all of the emotions may be regarded materially as intricate forms of vasomotor reflexes. Further reflexes are constantly operative and affect the normal metabolism of the skin or the bones, and still others are concerned in the general nervous equilibrium of the entire body—the so-called neuromuscular tone. See CONSCIOUSNESS; EMOTION; MUSCLE-SENSATION; NERVOUS SYSTEM; TELEPATHY.

REFORESTATION. See FORESTRY.

REFORM ACTS. See REFORM BILLS.

REFORM BILLS, in English history three bills, introduced in 1832, 1867 and 1882, for the purpose of increasing the electorate for the House of Commons and removing certain inequalities in representation. The first Reform Bill disfranchised many boroughs which enjoyed undue representation and increased that of the large towns, at the same time extending the franchise, and was put through by the Liberals. The bill of 1867 was passed by the Conservatives under the urging of the Liberals, while that of 1882 was introduced by the Liberals and passed in 1884; these two provided a more democratic representation. See GREAT BRITAIN; POLITICAL PARTIES; PARLIAMENT.

REFORM JUDAISM. See JEWS AND JUDAISM — REFORM JUDAISM.

REFORMATION, The. The Reformation was the movement in the religious life of western Europe in the 16th century which resulted in the formation of the Protestant Church. At earlier periods there had been a feeling that conditions in the leadership of Christendom needed improvement and attempts at betterment were made along two distinct lines. The first was through the efforts of individual men, monastic orders and general councils to bring about changes for the better within the Church. Such a movement was undertaken by the Reforming Councils of Pisa, Constance and Basel in the 15th century where an unsuccessful attempt was made to reform the Church in head and members. The

second way in which efforts had been made to improve the condition of Christendom was to form separate organizations outside of the Roman Catholic Church such as the Albigenses and Waldenses. These early separatist movements were not of any great importance because they affected only a comparatively small number of the Christians of Europe. These efforts to reform the Church from within and to establish other churches outside of Roman Catholicism had not met with success as the 15th century came to its close. The papal chair had been occupied for half a century by men who were more interested in the revival of learning and Italian politics than they were in giving Christendom the kind of leadership which it needed. Some of the popes contributed largely to the success of the Renaissance. Some were indifferent to religion and of immoral lives. The Reformation of the 16th century started as an effort to bring about reforms within the Roman Catholic Church, and it was only after this seemed impossible that the leaders withdrew from organized Roman Catholicism.

There are a number of reasons why the separation from the Church and the formation of a new organization met with success in the 16th century when the earlier efforts had failed. Most important of all was the revival of learning. Men were thinking for themselves as they had not before for centuries. The invention of printing brought about wide diffusion of knowledge. There was an opportunity through the study of the writings of the Early Church fathers to compare the Church of the first centuries in its belief and organization with the Church of the 16th century. It was evident to students that there was a wide difference between the two. The circulation of the New Testament also tended to bring about a diversity of opinion on religious matters. There was a growth of the national feeling in some of the nations of Europe, and an increasing desire that ecclesiastical affairs be handled within the nation rather than by the distant papacy, especially as the popes were involved in European politics. There was also a group of men who were fitted for leadership in the establishment of a separate Church. These men were able to accomplish what they did because of the growing consciousness that the Church as then organized and governed was not meeting the needs of the times, nor was it furnishing the moral and spiritual leadership which it had given in earlier centuries.

The Reformation began in Germany through the work of Martin Luther. A peasant by birth and a university graduate, he desired to make sure of his own salvation. He became an Augustinian monk and practised all the austerities of the order but did not find assurance of salvation. Through the help of friends in the order, by his study of the German mystics, and especially through the study of the New Testament he came to the belief that a man is not justified by works but by faith alone in Jesus Christ. Justification by faith came to be the foundation of his theology. He became professor in the University of Wittenberg and preached in that city. While he was here, the indulgence seller, Tetzel, began his work near Wittenberg and Luther preached against the sale of indulgences because it was

contrary to his conception of salvation by faith in Jesus Christ. On 31 Oct. 1517 he posted his 95 theses, in this way stating his own position on the subject and challenging to a debate. This brought him into conflict with the papal authorities and it was found that there were great numbers in Germany who accepted his views. Efforts were made to bring him back to the Church but in vain. His further study of the New Testament and the Church Fathers led him to take views directly antagonistic to the papacy. He taught that a general council could make mistakes, that all Christians were priests before God and that in matters of doctrine the papacy had departed from the teachings of the Bible. He was excommunicated and at the will of Emperor Charles V, placed under the ban of the empire but continued to be the leading spirit in the German Reformation. His most important assistant was his fellow-teacher at Wittenberg, Phillip Melancthon, the thinker and scholar of the Reformation as Luther was the aggressive leader. The Reformation spread rapidly after 1517 but was somewhat checked in 1524-25 by the Peasant Revolt because, in the minds of many, Luther's preaching led directly to such outbreaks. Luther's marriage also alienated some of his followers who did not believe that monastic vows ought to be broken. Efforts were made repeatedly at the German diets to come to some agreement but in vain. Feeling between Catholics and Lutherans became more bitter till war broke out between them, which was settled by the Peace of Augsburg in 1555 by which it was agreed that each prince should have it in his power to decide the religion of his people. The principle was expressed in the words *cujus regio ejus religio*. Another part of the agreement was the Ecclesiastical Reservation, according to which if an ecclesiastical prince changed his religion he must resign his benefices. This settled the ecclesiastical question in Germany for nearly a hundred years, but was unsatisfactory because it gave no room for the growing numbers of Christians outside of the Catholic and Lutheran bodies.

Meanwhile a similar movement was going on in Switzerland under the leadership of Ulrich Zwingli. He was a humanist and a great admirer of Erasmus. His study of the Bible led him to question some of the teachings of the Church and while preaching at the cathedral at Zürich he presented his new views. To settle the kind of preaching which should be allowed at Zürich a public disputation was held and the city government decided in favor of the Reformation. Similar action was taken by other cities of German Switzerland. The Lutheran and Swiss reformatory views were much alike, but with some striking differences. In order that there might be united and harmonious action by the two, a conference was arranged between the leaders of the two divisions at Marburg in 1529. They could agree on all points except on the Lord's Supper, the followers of Zwingli looking upon it as a memorial, while the Lutherans insisted upon the literal sense of the words, "This is my body," holding to the actual presence of the body and blood of Christ in the bread and wine but not to the change of the elements into the body and blood. All later attempts to bring about an agreement between the Swiss or Reformed

branch and the Lutherans failed. The Swiss forest cantons remained Catholic while the city cantons accepted the Reformation. There were other disagreements of a political nature so that war broke out and Zwingli was killed at the battle of Cappel in 1531. Zürich continued to be important as a centre for the propagation of the Reformation, but the leadership of the Reformed Church passed to Geneva.

There were many who believed that the Lutherans and Reformed did not go far enough in their rejection of error, and dependence upon the New Testament. These radical reformers were known as Anabaptists, because most of them rejected infant baptism and held that believers only should be baptized. They varied in life and belief from the learned and saintly humanist, Hubmaier, to the fanatic, John of Leyden. They were persecuted by Protestants and Catholics and many of them died as martyrs. The worst side of the movement appeared in the city of Münster, where an Anabaptist kingdom was established and polygamy was introduced. The large majority of the Anabaptists were sincere Christians, intent upon following the simple teaching of the Bible. They are the spiritual ancestors of millions of our present-day Christians.

In France there was no leading figure in the early days of the Reformation corresponding to Luther and Zwingli. The nearest approach to this was Jean Jacques Lefèvre, better known perhaps by his Latinized name, Faber Stapulensis, who was the leading humanist of his day in France. He came to a belief in justification by faith rather than by works before Luther did, and his translation of the New Testament into French greatly aided the Reformation. One of his pupils was Brignonet, bishop of Meaux, who undertook reformatory work in his own diocese and invited preachers of Reformed views to assist. He never went so far as to break with Roman Catholicism and when protests were made against the preachers he had brought in he ordered them to withdraw. But the work which had been begun went on in secret in Meaux and in other parts of France. Faber never withdrew from the Roman Catholic Church.

The attitude of the French king, Francis I, varied from time to time according to political exigencies, but became more hostile to Protestantism as time went on. He was greatly disturbed by the Peasant Revolt in Germany, fearing that the spread of the new faith might bring anarchy into his own country. In his closing years the laws against heresy were rigidly enforced but Protestantism continued to spread. The great growth of Protestantism in France came after the Frenchman, John Calvin, became master of Geneva and made that city the centre of the Reformed branch of Protestantism. Frenchmen went to Geneva and returned to their homeland to distribute copies of the New Testament and to preach, when they knew that they risked their lives by so doing. The persecuted Christians were organized into churches under the direction of Calvin. The Presbyterian system was established and even in the days of persecution a national organization was effected. The French Protestants were called Huguenots and became a political as well as religious party. As in so many other nations of Europe, war broke out between the

followers of the two faiths. These wars succeeded each other rapidly for a period of half a century with varying results. Finally Henry of Navarre became king. He was a Protestant, but to put an end to the civil wars he became a Roman Catholic. In 1598 he published the Edict of Nantes which gave a limited toleration to the Huguenots and under which they increased in numbers for nearly a century.

A second and more important branch of the French Reformation was that which had Geneva as its centre. Geneva had accepted the Reformation principally through the efforts of French evangelists of whom William Farel was the leader. He attempted to make the people of Geneva live up to their professions but was unable to do so. The work which he began was carried on by John Calvin in such a way that Geneva became the model city of Protestant Christendom. John Calvin was famous before his coming to Geneva as the author of the 'Institutes,' a book which more than any other became the textbook of the Reformed Church. Calvin fled from France because of the persecution and hoped to find some city where he could spend his life in scholarly work for the Reformation. On his journey he chanced to come to Geneva to pass the night. Farel was trying to organize the Church and he persuaded Calvin to assist him. After a prolonged conflict Calvin gained control of the city. He reorganized the Church under the eldership system by which ministers and lay elders had control of the spiritual affairs of the city. He established theological lectureships, thus making possible an educated ministry. Geneva became the educational centre of the Reformed Church and large numbers of men, fleeing from persecution in England, the Netherlands, France and other parts of Europe, came to Geneva, studied under Calvin and carried his theology and form of Church organization back to their home lands.

The Reformation came early into the Netherlands because of its close commercial and political connection with Germany. Charles V attempted to put a stop to the spread of the movement but the laws against heresy were not executed with strictness in his reign. His son Philip II entered upon a more vigorous policy of persecution and through the Duke of Alva and his successors tried in vain to suppress the political and religious liberties of the Netherlands. The great leader in the struggle for independence was William of Orange, at first a Catholic and in his later years a member of the Reformed Church. The inquisition of the Spanish type was introduced and the laws of the country were suspended. Persons accused of heresy were executed by the hundreds. Philip resolved to root out heresy even if it meant the ruin of the country. In vain the best generals in Spain were sent to overcome the resistance of the people. Under the guidance of William of Orange the northern provinces which were almost wholly Protestant declared their independence of Spain, which was finally established at the close of the Thirty Years' War.

England had been influenced by the Humanistic movement through the work of More, Colet, Erasmus and other leaders of the Renaissance but their effort was rather to purify the Old Church than to form a separate organiza-

tion. The immediate cause of the separation was the act of the king who desired a divorce from his queen, Catherine. The Pope was not willing to grant this and so Henry took the matter into his own hands and declared himself the supreme head of the Church of England, obtaining his divorce through Cranmer, archbishop of Canterbury. Parliament, under the control of Henry VIII, passed a law which took all authority in England away from the Pope and the king became supreme in all matters relating to the temporal affairs of the Church in England. No appeal could be taken on any ecclesiastical matter to any power outside the realm. It was the plan at first to make no changes in doctrine but there was a strong Protestant tendency under the leadership of Archbishop Cranmer. This was made evident by the publication of the Ten Articles which formed the first statement of belief of the separated English Church. Henry encouraged the reading of the Bible because he thought this would strengthen the movement away from Rome, not realizing that the study of the Bible would bring independence and diversity of belief amongst his people. There was a strict understanding that all the people should walk in the ecclesiastical path which Henry had marked for them. Those who refused to do so were subjected to the king's displeasure and in a few instances were executed for refusing to acknowledge him as supreme head of the Church in England or for declining to follow him in his doctrinal changes. One of his most drastic changes was the dissolution of the monasteries. A royal commission was appointed to investigate their condition and this commission brought in an adverse report so that they were dissolved, the smaller ones at first and the larger ones later in his reign. The property of the monasteries was used in part for educational and religious purposes but the larger part was used to enrich the king and the landed gentry. Henry's reign closed in 1547, and he was succeeded by his 10 year-old son, Edward VI, who because of his youth was under control of regents. The movement toward a Reformation of the Continental type was rapid in his reign under the leadership of Cranmer. Theologians from the Continent were brought in to assist in the movement. The first Prayer Book of Edward VI was published largely through the influence of Cranmer. This is the basis of the present Book of Common Prayer. Forty-two articles of Faith, afterward reduced to Thirty-nine, formed the doctrinal basis of the Church.

In 1553 Mary the daughter of Henry VIII and Catherine became queen and attempted to undo all that had been done in the direction of Protestantism in the preceding reigns. She tried to have the men who had been enriched by the abbey lands give back these lands to their former owners, but in this she did not succeed. The nation returned to allegiance to the Pope with an ease that made it clear that England was not yet ready for the change to Protestantism. Mary enforced the heresy laws, especially against those who had been prominent in the overthrow of Roman Catholicism, some of the leading Churchmen of England being included in the list of her victims. The fortitude of these unfortunate ones as they were burned at the stake did much to turn the

minds of England to a study of the Reformation. More and more in the reign of Mary, England was becoming Protestant and the queen had the consciousness in her closing years that her efforts to turn the nation to the Old Church had been a failure. When Elizabeth succeeded to the throne in 1558 she found conditions which required the exercise of great wisdom to keep the nation from civil war. She was herself a Protestant by taste if not by conviction. The changes introduced by Mary were quickly abolished. A new Act of Supremacy was passed which made her Supreme Governor on Earth of the Church in England. With her accession the Protestant leaders who had fled to the Continent when Mary began her prosecutions came back and brought with them ideas which were in conflict with the thoughts of Elizabeth in regard to the royal supremacy. These Puritans as they came to be called were not opposed to the idea of Episcopacy but they did object to what they considered the remnants of popery in the system which still retained forms and customs suggestive of Roman Catholicism. They desired a State Church purified from all that had suggestion of popery and one in which there was a large degree of freedom in the way of forms and ceremonies. In the later years of Elizabeth there was a party believing in Presbyterianism as the only proper form of Church government and they desired to have one established State Church but of the Presbyterian type. There also appeared the various independent movements out of which the Congregationalists and Baptists later arose.

While we associate John Knox more than anyone else with the Reformation in Scotland, there were several men who prepared the way for him. One of these was Patrick Hamilton, a young nobleman who studied at different universities on the Continent and came to the Protestant position. He returned to Scotland and preached the new views. Cardinal Beaton was primate of Scotland and resolved to suppress heresy. Hamilton refused to change his views and was burned at the stake. George Wishart was another enthusiastic preacher of the Protestant views. He was protected by the nobles who were friendly to his teachings and he made evangelistic journeys in different parts of Scotland. One of his followers was John Knox. Wishart was captured and executed for heresy and Knox became the leader of the Scotch Reformation. He had obtained a priestly education and soon showed marked ability as a Protestant leader. He worked in England in the reign of Edward VI and went to the Continent when the persecution broke out in the reign of Mary. He studied at Geneva and adopted Calvin's views in regard to Church organization and theology. On his return to Scotland in 1559 he became virtually the head of the Protestant movement in that country. He gave his support to the Lords of the Congregation in their attempt to maintain Protestantism against the wishes of Mary Stuart, who desired to hold the nation to Catholicism. The conflict resulted in a victory for Protestantism and Presbyterianism was established by law. After Knox's death in 1572 his work was ably carried on by Andrew Melville.

The Reformation was also introduced into Denmark, Sweden and Norway. The leaders were men who had been pupils of Luther and

the Reformation was under state control. It was in some cases forced upon the people before they had been thoroughly informed of the meaning of the change. Educational work was carried on later so that the Scandinavian countries became thoroughly Protestant.

The Lutheran Reformation also extended into Bohemia, Hungary and Poland. In Bohemia the way had been prepared by Huss and his followers. It spread rapidly here but was almost entirely overthrown by the work of the Jesuits and the Thirty Years' War. In Hungary and Poland the progress of the Reformation was greatly hindered by the rivalries of Lutherans, Calvinists and Unitarians.

Attempts were made by the Roman Catholic Church to recover the ground lost and to gain new territory in the non-Christian world. The principal agency in this effort was the Society of Jesus, an organization founded by the Spanish monk, Ignatius Loyola. The new religious order placed itself under the power of the Pope to be used unreservedly by him in the service of the Church. It worked along two lines — educational and missionary — and was so successful that in some parts of Europe the Reformation was held in check, in other places large numbers who had been Protestants were won back to Catholicism. In non-Christian lands the members of the Society worked as missionaries and thousands were won to Catholicism. (See COUNTER REFORMATION). Consult Fisher, 'History of the Reformation' (1893); Newman, 'Manual of Church History' (1903); Walker, 'The Reformation' (1900); Lindsay, 'History of the Reformation' (1907); 'The Reformation' in the 'Cambridge Modern History' (1907).

CURTIS M. GEE,

Professor of Church History, Hartford Theological Seminary.

REFORMATORIES. See PENOLOGY.

REFORMATORY SCHOOLS, schools instituted for the training of juvenile offenders who have been convicted of an offense punishable by imprisonment. The first reformatory managed under legislative control was the one established in New York in 1824, known as the New York House of Refuge. Its success was so marked that at present there are 56 institutions in the United States for the reformation of juvenile offenders. Among them are a number of admirably conducted establishments under the control of religious denominations, in which children are sent, according to the religious creed of their parents, when the same can be ascertained.

REFORMED CATHOLIC CHURCH.

religious body established in New York in 1830 by several priests who had left the Roman Catholic Church, and under the leadership of Rev. James A. O'Connor. It adopted the Protestant doctrine as expounded in the Evangelical churches, and protested against the doctrine, government, discipline, practice and sacramental system of the Roman Catholic Church. They believe that the believer finds salvation through faith in God through Christ and needs no mediation through the church. They have six churches, eight ministers and about 3,000 members. The sect is established in New York, Massachusetts, Pennsylvania and Illinois.

REFORMED CHURCH. See CALVIN, JOHN; CALVINISM; REFORMED CHURCH IN AMERICA; REFORMATION.

REFORMED CHURCH IN AMERICA. The, is one in denominational polity and doctrinal type with the Reformed Protestant Dutch Church of the Netherlands, and bore that name until the year 1867. The beginnings of distinctive Reformed Church theology should be credited to "The Brethren of the Common Life." This was a unique organization of Christian community-life throughout the Netherlands, indirectly inspired by the consecrated mystic, John Ruysbroek of Brussels, designed and formally established at Deventer and Zwolle in North Holland by Ruysbroek's devoted pupil and friend, the enthusiastic evangelist-missionary, Gerard de Groote, in the last year of his life, 1384, and fully organized and developed by de Groote's like-minded fellow-worker, Florentius Radewyn, during the last 16 years of the 14th century, which were also the closing and crowning years of the life of this truly diligent and admirable man. Absolute loyalty to the will and person of the Lord Jesus Christ in everything, as necessarily exemplified in continual personal study and obedience of the Holy Scriptures, was the one all-important purpose in the daily life of these single-hearted Christian leaders. For the more practical and complete realization of their one supreme purpose many varied personal and community activities were developed; conspicuous among these were transcribing and multiplying copies of the Old and New Testaments, the early Church Fathers and other truly good books; the grouping of these "copyists" in community-families of not more than 20 persons under the same roof; daily study of the Scriptures, the classic languages and the simpler sciences; the establishing and employing of schools, academies and colleges for the educating of the youth; providing needed teachers as well as needy students in already flourishing schools—with the special design of encouraging and helping every ambitious boy to an education anywhere in the Netherlands; and daily, ordered and useful work of some kind for every person; for preaching Christ and Christian duty, teaching, publishing, farming, gardening, sharing handiwork of any and every useful kind, made up the regular program of the "Brethren of the Common Life." This carefully organized Christian system, during the century preceding the dawn of the great Reformation, produced such men as Thomas à Kempis, saintly author of 'The Imitation of Christ'; Rudolph Agricola, famous for reviving classical studies and freeing learning from scholastic fetters; Alexander Hegius, the greatest educational reformer of his age; Desiderius Erasmus, the foremost humanist, scholar and author of the Renaissance; and John Wessel, more popularly known as Wessel Gansfort, philosopher, physician and pioneer organizer of the earliest Protestant theological system.

Besides these eminent men, the schools of the "Brethren of the Common Life" trained a great number of lesser leaders, who were influential for better things in education, and morals and spiritual life. De Groote and Florentius appreciated the value of the spiritual treasures bequeathed to them by the great-

est of all the mystics, Ruysbroek, the venerable abbot of Gruenthal, and Tauler, the impassioned evangelist of the Rhine Palatinate; and realizing clearly the supreme crisis of their time, and their own supreme obligation through the service of fellow-men to seek the greater glory of God, they established wisely and permanently their efficient brotherhood of Christian communities, which directly for nearly two centuries, and indirectly for all succeeding time, was influential in making Holland pre-eminently the home of civil, intellectual and religious liberty. And to these founders and trained leaders of the "Brethren of the Common Life" the Reformed Church in Holland and in America is indebted—above all others—for a religious faith always scriptural, simple and spiritual, which exalts to supreme place the salvation and imitation of the Divine Redeemer, the imperial authority of Holy Scripture, the Fatherhood of God and the true love and service of mankind. These men in Holland shared with Wyclif of England and Huss of Bohemia the honor of faithful preparatory work in the 14th and 15th centuries as evangelical reformers before the Reformation.

Early in the development of 16th century reform the people of Holland showed marked preference for the doctrinal system of Zwingli and Calvin rather than that of Luther. This may have been partly due to their long-time neighborly intercourse and friendship with the Evangelicals living on the banks of the Rhine, and partly due to their sympathy with the persecuted disciples of Calvin in France; but chiefly due, it may well be urged, to the clear, convincing and fearless propaganda of Wessel Gansfort—a man of such culture, conviction and persuasive power that his two years' professorship at Heidelberg University established a virile and abiding evangelical influence in those academic halls which had marked effect upon Ursinus and Olivianus and the Heidelberg Catechism. Without doubt also Gansfort directly, or indirectly, helped to shape the Belgic Confession as truly as that great symbol influenced the countrymen of Gansfort in later years. It may be remembered that Martin Luther himself wrote concerning the writings of Gansfort: "If I had read his works earlier, my enemies might think that Luther had absorbed everything from Wessel, his spirit is so in accord with mine."

The persecutions for heresy under Charles V of Spain (1519-55), and his son Philip II (1555-98), brought long-continued distress and suffering to the Netherlands people, and continued with occasional brief intervals for more than half a century. The period of horrors, par excellence, was the bloody six years' régime of Alva (1567-73), during which time, as the princely butcher boasted, there were more than 18,000 authorized executions; and it is claimed that in this little country more than 100,000 persons gave up life rather than faith. The more cruelly they were persecuted, however, the more inflexibly the Hollanders refused the obedience their Spanish king demanded. In 1584 William of Orange, the shrewd, self-sacrificing, invincibly fearless and confident defender of Holland's faith and freedom, was treacherously assassinated by Balthazar Gerard; yet his son Maurice proved himself a skilful military leader, and with some little help from

England the struggle with the oppressor continued for some years; but finally in 1609 the "twelve years' truce" was agreed upon and Holland's long-protracted agony for conscience's sake was over. Yet during the darkest days of persecution proscribed evangelists continued their fervent preaching in the fields, and the people prayed and sang praises to God, after the example and spirit of the imprisoned apostles—the appeals of the field-preachers and the inspiring hymns of Beza and Marot continually strengthening them all to persevere in "witnessing a good confession."

Just before the coming of Alva, in 1566, a few Dutch and Walloon pastors organized the first evangelical Church Synod at Antwerp; and with the aid of a few noble laymen a complete Church organization was effected. The Belgic Confession, written by Guido de Brey five years before, was adopted, with slight changes; and the Heidelberg Catechism, now for three years the authorized symbol of the Palatine reformers, was accepted tentatively, to be fully and finally adopted a few years later. Yet it was distinctly professed, whatever doctrinal standards were honored or endorsed, that the Word of God was the only recognized rule of faith. The Synod of Wesel in 1568 somewhat modified and adopted Calvin's Presbyterian polity; the necessity for a learned and consecrated ministry, loyal to the Word of God and the Church standards, was plainly set forth, and the various classes and duties of church officers were clearly defined. In 1571 came the Synod of Emden, which endorsed the acts of previous synods and formulated certain new features of church government. The first Synod of Dort, 1576, defined the four grades of ecclesiastical bodies as follows: the General Synod, the highest court, its members delegated from the Classes, and meeting once a year; the Particular Synod, also a delegated assembly of ministers and elders, meeting annually; the Classis, a permanent body including the pastors and one elder each from a number of nearby churches, and meeting twice a year, and the Consistory, the court of the individual church, consisting of an equal number of elders and deacons elected by the church, with the pastor as president. The same Synod also limited certain conditions of church membership. Five years later the Synod of Middleburg assembled in 1581 to complete the organization of the Church and to determine certain matters relating to schoolmasters, professors of theology, liturgy and creed. A month later the sovereignty of Philip II was formally renounced, and the Reformed Church was declared the established Church of the Netherlands. The great Arminian controversy early in the 17th century made necessary the calling of the second Synod of Dort in 1618, to which all the Reformed Churches of Europe were invited, and most of them consented, to send delegates. James I commissioned as England's representatives the bishop of Llandaff, Samuel Ward, professor of Cambridge, and Joseph Hall, afterward a bishop of Salisbury. Foreordination, perseverance of the saints, man's conversion and free will and the divine atonement were elaborately discussed; under the leadership of Episcopius (Arminius having died before the Synod convened), the

Remonstrants warmly favored the system of Arminius, which, in certain points, was finally adjudged contrary to sound doctrine; the Arminian Remonstrants were excluded from office in the Reformed Church, as consciously and wilfully traversing their own solemn pledges of loyalty to the Church and its standards; and in an elaborate formula known as the "Canons of the Synod of Dort," the Synodal decisions concerning the great doctrines of grace were carefully defined. The "Post Acta" of the later sessions of the Synod set forth authoritatively certain important details concerning the call to the ministry, festival days, hymns for worship, baptism of adults and the sick, professors of theology and their relations to the Church, a new translation of the Bible into Dutch, foreign missions, the Liturgy and ministers' salaries. The Heidelberg Catechism was again heartily adopted, and a "Compendium" of its teachings was prepared that it might be included with the other standards of the Church.

Four years before this time the Hollanders began emigrating to America; for that new-discovered world became increasingly attractive year by year, since the Holland government had formally annexed the country discovered and partially explored as "New Netherland," and had issued a charter to the East India Company, with specified rights of trading, settling and colony improvement. Within a half dozen years after Henry Hudson, in 1609, had discovered the river that bears his name the Dutch trading posts at New York and Albany had the services of specially qualified and ordained Christian laymen (Jan Huyck and Sebastiaen Jansen Krol by name) as "Comforters of the Sick" and leaders of public worship on Sundays. A distinctly aggressive religious influence was also due to the consecrated personality of the first director of the colony, Peter Minuit, who had been for years an ordained elder of the French Reformed Church of Wesel.

In seeking their comfort and growth, spiritual as well as temporal, at both Albany and New York, these three Christian laymen served their fellow-colonists for some years before the coming of the first missionary minister of the Dutch colony, the Rev. Jonas Michaelius, in the year 1628. Soon after the coming of this minister the first Reformed church was organized with 50 communicants. Many of the early settlers of New Netherland were French Huguenots, more commonly called "Walloon." The name of the Long Island locality, "Wallabout," shows the nationality of most of the people who settled there. In 1642 the people of Albany (Fort Orange) were no longer obliged to content themselves with the spiritual ministry of the "Comforters of the Sick," for Kilian van Rensselaer, the first patroon of Rensselaerswyck, secured for them the services of a well-qualified minister, the Rev. Johannes Megapolensis, and in August of 1642 the first minister of Albany began his seven years' pastorate. It is worthy of note that the Classis of Amsterdam (having sole ecclesiastical jurisdiction over New Netherland), which commissioned Megapolensis for his work, also specified in his "call" that his duty was to minister to the spiritual needs of the Indians as well as

the Dutch, and the same duty was prescribed in many other Classis "calls," which served as official commissions of the ministers for their work, whether on the Hudson River, the Delaware, the Mohawk or the Raritan. Early in his ministry at Albany Megapolensis prepared and published a detailed account of the Mohawk Indians, which is the earliest trustworthy book on the life, customs and characteristics of the American Indian. In 1654 a third Reformed church was organized at Flatbush, L. I., with Polhemus as pastor; and other churches were established during the next 10 years, so that at the time of the English occupation in 1664 they numbered 13 in all.

During the next century the need of ministers for the steadily growing American church became more and more urgent; there were no American colleges and seminaries available to prepare students for ministerial service; but few young men could afford the time and expense necessary for seven years of academic and theological study in Holland; and the Reformed Church was thus hindered and dwarfed in the most important stage of its growth. Another condition limiting the increase of the Church was the continued and exclusive use of the Dutch language for more than half a century after it should have been clear to any thoughtful person that this persistent stand of the Dutch Church was a steadily losing policy which must finally bring disaster. Whether among Dutch settlers in America of the early 17th century or among German settlers in America of the early 20th century—to make the language of the street, and social life and business, the language of the school, the newspaper and the Church, is evidently a policy profitable, sensible, Christian and patriotic.

Another obstructive influence, which co-operated all too well with the injurious tendencies already noted, was the propaganda of many leading Episcopalians, crafty or aggressive, persuasive or argumentative, but at all times persistent, which often triumphed, in capturing from the Dutch Church many of her most wealthy and influential communicants. Yet another influence, most lamentable of all in its injury of vital interests, was the long "Coetus-Conferentie" controversy, which seriously crippled and divided the Church from 1755 to 1771. Harmony was at last restored through the wise and gracious activities of Dr. John Henry Livingstone. He was a graduate of Yale College, and later of the theological department of the University of Utrecht, Holland; and he brought with him, as a Dutch doctor of divinity set apart by the Classis of Amsterdam as minister of the Collegiate Church of New York, a most valuable content of influence in the approving counsels and hearty co-operation of the churches of Holland in his plan for reconciliation and peace. (The adoption of the Plan of Union virtually removed the American Church from the jurisdiction of the Classis of Amsterdam; 21 years later absolute independence came with the new constitution). Dr. Livingstone later in life was professor of theology in the New Brunswick Theological Seminary for many years (1784-1825), and 15 years before his death he was also elected president of Rutgers College. Long-cherished plans for a Church college were realized when Governor Franklin granted a charter in 1766; but Queens

College (later Rutgers) was organized under a second and improved charter in 1770, and was permanently located in New Brunswick, N. J. Besides the theological seminary at New Brunswick, the Reformed Church has a second theological seminary at Holland, Mich., and a third in connection with the Arcot Mission of the Reformed Church in India.

Near the middle of the 19th century there was an extensive immigration from Holland to Michigan and the neighboring States; and the rapid growth of this large Holland colony led to the founding of Holland Academy, which afterward so steadily prospered that it was chartered as Hope College in 1866. Youngest of the colleges of the Church is Central College, located at Pella, Iowa, which, after 63 years of work under the auspices of the Baptists, was transferred to the control of the Reformed Church in 1916. A board of education was established in 1828 with the design of aiding the most desirable young men in preparing for the ministry; and in 1865 the board was empowered by General Synod to aid the Classes of the Church in establishing academies and classical schools. Since 1844 the board of domestic missions has done efficient work in strengthening feeble churches and in supporting infant churches. With several other denominations the Reformed Church was associated in the foreign missionary work of the American Board from 1832 to 1857; since then it has had its own separate missionary work with special responsibility for fields in India, China, Japan and Arabia.

In government the Reformed Church in America is Presbyterian; in public worship the use of the Liturgy is optional, with the exception of the Offices for Baptism, the Lord's Supper and ordination of ministers, elders and deacons.

In 1792 the constitution of the American Church was formed, the 84 articles of the Synod of Dort being enlarged by adding 73 explanatory articles, more perfectly adapting the church law of the older Church to the requirements of modern Christian life in the "new world." During the last 10 years also many constitutional changes, in form or in substance, have been proposed, discussed, modified and finally ratified. Four officers of the Church are recognized: ministers of the Word, professors of theology, elders and deacons. The judicatories of the Church are also four: the Consistory, the Classis, the Particular Synod and the General Synod. The Consistory of each church includes the minister with the elders and deacons in active service; the elders being charged with spiritual functions and the deacons with the care of the poor; the Consistory are usually the sole trustees of church property; the elders and deacons are elected by the church members for a term of two years; and rotation in office changes half the Consistory each year; the great Consistory is an advisory body of elders and deacons formerly in service. The Classis must have not less than three ministers and three elders, representing at least three churches; it meets twice a year, to license, ordain, install, dismiss, suspend or depose ministers, and legislate on the affairs of the churches, trying cases appealed from them. The Particular Synod has jurisdiction over its constituent Classes, forms new Classes or transfers

congregations from one to another, and decides cases of appeal; it meets once a year and is composed of four ministers and four elders from each Classis. The General Synod, the court of final appeal, convenes early in June of each year; has jurisdiction over the entire Church; has a representation of at least two ministers and two elders from each Classis; and sends down to the Classes proposed and desirable changes in the constitution of the Church, to be finally decided for or against by their majority vote. In 1918 the Reformed Church in America had one General Synod, four Particular Synods, 38 Classes, 730 churches and 759 ministers, with 132,937 communicants. in America.*

REFORMED CHURCH OF AMERICA, Board of Education of, a body organized in 1828 by the General Synod to administer funds for the sustenance of needy students in the ministry. It was incorporated in 1869; since then it has managed the scholarship funds independently of the synod. Rutgers College is named for the first president of this board, Col. Henry Rutgers. See REFORMED EPISCOPAL CHURCH.

REFORMED CHURCH IN THE UNITED STATES (The), commonly known as the German Reformed Church, was founded by immigrants from Germany and Switzerland who came to the New World during the 18th century, in several instances driven hither by persecution. Some went to Virginia, in which the first congregation was organized as early as 1714. Most of the immigrants settled in Pennsylvania. There the scattered bands were organized slowly into congregations through the efforts of John Philip Boehme, a schoolmaster, and of the Revs. George Michael Weiss and Michael Schlatter, aided by men and money sent by the *Reformed Church of the Netherlands* (q.v.). The assistance given them by the Dutch Church naturally led to their subjection to the Classis of Amsterdam, which from 1725 till 1792 exercised jurisdiction over the *Coetus*, as the ecclesiastical gathering in America was called which met from year to year, composed of the pastors of the congregations and one elder from each consistory or local session. In 1793 the German churches assumed independence by constituting themselves as a *Synod*, which at the time enrolled 22 pastors, 178 congregations and about 15,000 communicant members. The churches multiplied considerably during the next half century, by means of increased immigration, the effects of a revival, which lasted from 1829 till 1844, and by the use of modern methods in church work,

such as the Sunday school and missionary efforts, although in some districts the growth was impeded by the vexing problem of the inevitable transition from the use of the German language to that of the English in church services, something which in some instances caused deplorable divisions. The lack of ordained ministers also interfered with the progress of the denomination, a couple of attempts to found theological seminaries ending in dismal failure. In 1844 the Church began to be disturbed by the so-called liturgical controversy, which did not end until 1878, when a peace committee was appointed to settle the difficulty. In 1863 the Eastern Synod and the Synod of Ohio united to form the *General Synod*, meeting every three years. At present there are nine synods, viz.: those of the Southwest, Interior, Central, German of the East, Potomac, Pittsburgh, Northwest, Ohio and Eastern. The membership of these various synods totals (1918) over 330,000 communicants, forming 1,785 churches, served by 1,300 ordained ministers. The theological seminary of Lancaster, Pa., is the oldest ministerial training school of the Church, dating from 1825. In Dayton, Ohio, the Central Theological Seminary is located. A third theological school is near Sheboygan, Wis., called the Mission House. Several colleges and academies are under auspices of the denomination, Franklin and Marshall College being the oldest. An extensive home mission work is carried on by two boards, under various nationalities, notably among the Hungarians and Germans. Foreign mission work is carried on in China and Japan, in each country with about 30 ordained pastors. The publication work of the denomination is very extensive, including several periodicals, of which the *Reformed Church Messenger* (Philadelphia) is the oldest. The doctrinal standard of the Church, the Heidelberg Catechism, is regularly taught to the youth of the Church. The rite of confirmation of the new communicant members is celebrated with solemnity. The Sabbath school is flourishing. The official book of praise, the "Hymnal," was superseded in 1919 by a hymnbook published jointly by the Reformed Church, United States, and the Reformed (Dutch) Church in America. Prior to 1870 the 150 psalms were used in the song service. Since that date hymns only are employed. The government of the Church is presbyterial, according to the "Constitution," which contains some 200 articles and is based on the Church Order of Dordrecht. Doctrinally the position of the denomination is broad and tolerant. Attempts to effect union with the Reformed Church in America and the Presbyterian Church (North) have hitherto borne no fruit.

HENRY BEETS.

REFORMED CHURCHES IN SOUTH AFRICA. The Union of South Africa contains six Reformed Churches. The oldest of these is the Dutch Reformed Church of the Cape province, dating from 1652 and numbering about 160 congregations, some of which are located in Rhodesia and Mashonaland. Its theological seminary is in Stellenbosch. Three missionary training schools and several philanthropic institutions are maintained by this Church, which in liturgy, doctrine and polity is in accord with the other reformed churches

of Dutch origin. Both psalms and hymns are sung in public worship. The highest church court, the Synod, meets as a rule every three years. The Dutch Reformed Church in the *Orange Free State* became independent from the Cape Church in 1853. It numbers 61 congregations. In the *Transvaal province* the Dutch Reformed Church, dating from 1866, reports an enrolment of 71 churches, while the *Natal* denomination of the same name numbers seven congregations. Since 1906 the Dutch Reformed Churches of these four provinces have a common bond of union in their "Federal Council" which secures their co-operation in many ways. The weekly organ of these churches is *De Kerkbode*, Capetown. A vigorous mission work is carried on by the above-named denominations within their own territory as well as north and south of the Zambesi River. Some Boer missionaries labor in the Sudan. *De Koningsbode* is the missionary monthly. As a result of this missionary activity among the African natives over 100,000 persons belong to their "mission churches." They form synods of their own. The *Reformed Church in South Africa*, a body composed of about 80 congregations, dates from 1858, when its founders seceded from the Dutch Reformed Church. It is found in the Cape province, Free State and Transvaal. Psalms are used in public worship, and not any hymns. The theological school of the denomination is located in Potchefstroom. Church organ, *Het Kerkblad*. This body is very conservative. Mission work is carried on among the natives, although on a small scale. Much stress is laid on the erection and maintenance of free Christian primary schools. The late President Kruger was one of the leading men of this denomination, usually known as the "Dopper Church." The *Reformed (Hervormde) Church of Transvaal* is the smallest Dutch denomination in the Union of South Africa. Dating from 1853, it has been unable to pass beyond the boundary lines of the Transvaal, and in 1918 reported 32,500 souls. Its seminary is in Pretoria. The Reformed Church numbers 35,000 souls. The four Dutch Reformed churches total (1918) 525,000 souls—of whom about 150,000 are communicants. African Dutch is fast becoming the official language of all the denominations mentioned above, instead of the Holland language as hitherto.

HENRY BEETS.

REFORMED EPISCOPAL CHURCH, a denomination organized by members of the Protestant Episcopal Church, who give substantially the following statement of the events and circumstances which, as they believe, justify their course: (1) The Protestant Reformation in England had outwardly a political origin (in the act of the king, Henry VIII, renouncing allegiance to the Pope, and proclaiming himself head of the English Church); by which the work was biased and cut short. During the brief life of the young king, Edward VI, the regent, or protector, being in favor of the Reformation, great progress in it was made. Under Mary the supremacy of the Pope was again acknowledged. When Elizabeth became queen, wishing to harmonize her divided subjects, and hoping for reconciliation with Rome, she strove to have the Liturgy framed so as to

satisfy both parties. Consequently it contained contradictory elements. At a later period, when she had found her hope futile, the articles of faith adopted were decidedly Protestant. Thus it came to pass that in the Church of England two parties found support in her Ritual; the one Protestant, the other having an affinity with Rome. (2) After the American Revolution, when the Church of England in the colonies became the Protestant Episcopal Church of the United States, the Book of Common Prayer, having been adopted without material alterations, retained its conflicting elements. (3) The Tractarian movement, which began at Oxford, 1833, was a successful endeavor to revive the principles of antiquity and Catholicity contained in the Prayer Book, in opposition to its Protestant elements. It discarded Protestant principles and taught the doctrines of apostolic succession, priestly absolution, baptismal regeneration, the real presence and the authority of the Church. (4) These teachings produced a powerful effect in the United States also. A great increase in ritualism, and of the drift toward Rome, was soon manifested; the opposition between the "High" and the "Low Church" parties was intensified, and practical measures were adopted by each which widened the chasm. (5) Several subsequent public events fanned the flame of discontent, especially the censure of one clergyman for preaching in a Methodist church, and the suspension of another for omitting the word "regenerate" in the baptismal office. (6) Remonstrances and petitions for relief, which were numerous and urgently presented to the General Convention, produced no effect. (7) During the sessions of the Evangelical Alliance in New York in October 1873, Bishop Cummins of the diocese of Kentucky, having, by invitation, officiated at a union celebration of the Lord's Supper, in company with representatives of other denominations, was for this act of Christian fellowship bitterly censured through the press by members of the High Church party. After this, convinced that he could no longer rightfully continue in a Church whose theory and practice (as interpreted by the majority of its members) denied the brotherhood of believers in Christ, Bishop Cummins withdrew from the ministry of the Protestant Episcopal Church. (8) This led to the organization in 1873 of the Reformed Episcopal Church, of which Bishop Cummins and the Rev. Dr. Charles E. Cheney were elected bishops. At the same time the following declaration of principles was adopted: I. The Reformed Episcopal Church "holding the faith once delivered to the saints" declares its belief in the Holy Scriptures of the Old and New Testaments as the Word of God, and the sole rule of faith and practice; in the creed "commonly called the Apostles' Creed"; in the divine institution of the sacraments of baptism and the Lord's Supper; and in the doctrines of grace substantially as they are set forth in the Thirty-nine Articles of Religion. II. This Church, recognizes and adheres to Episcopacy, not as of divine right, but as a very ancient and desirable form of Church polity. III. This Church, retaining a liturgy which shall not be imperative or repressive of freedom in prayer, accepts the Book of Common Prayer, as it was revised, proposed and recommended for use by the General Convention of the Protestant Church, 1785; re-

serving full liberty to alter, abridge, enlarge and amend the same as may seem most conducive to the edification of the people, "provided that the substance of the faith be kept entire." IV. This Church condemns and rejects the following erroneous and strange doctrines as contrary to God's word: (1) That the Church of Christ exists only in one order or form of ecclesiastical polity. (2) That Christian ministers are "priests" in another sense than that in which all believers are "a royal priesthood." (3) That the Lord's table is an altar on which the oblation of the body and blood of Christ is offered anew to the Father. (4) That the presence of Christ in the Lord's Supper is a presence in the elements of bread and wine. (5) That regeneration is inseparably connected with baptism. To this statement it may be added that in this Church the bishops do not constitute a separate order, but are presbyters; in council they vote with and as their brother presbyters, and are subject to confirmation or appointment by the general council. Statistics, 1910: Churches, 80; ministers, 94; members, 9,610. The present bishops are Samuel Fallows of Chicago, Robert L. Rudolph of New York, William Brewing of Toronto and Arthur L. Pengelley of Charleston, S. C.

REFORMED SCHOOL OF MEDICINE. See MEDICINE, ECLECTIC.

REFRACTION, a deviation in the course of a ray of light when it passes through the surface of a transparent medium. A familiar result of refraction is seen when one looks very obliquely into a transparent pool of water, of which the bottom is visible. The water seems much shallower in such a case than it really is. Another example is the bent appearance of the oars of a boat when the blades are seen obliquely under water. When ordinary light is refracted, it is also decomposed into light of the various elementary colors. This decomposition is due to the unequal refraction of light of different wave-lengths; and the resulting separation is known as *dispersion*. It is too small to be noticed in ordinary cases, such as those we have already cited. But, on looking at a source of light through a glass prism, it is very evident. See LIGHT; SPECTRUM.

The general theory of refraction is quite simple, and may be expressed in the following way: The power of a transparent medium to refract a ray of light is expressed by a certain number called its *index of refraction*. The phenomenon of dispersion shows that this number is different for rays of different colors, or wave-lengths. It is generally greater the denser the medium; but to this rule there are many exceptions. The mathematical principle by which the amount of refraction is determined is as follows: Let AB represent the surface of a transparent medium, LM. Let a ray of light, PQ, strike this surface obliquely at Q and enter the medium, and let QR be its course through the medium. Draw through Q the perpendicular DE. Then the angle PQD which the ray makes with the perpendicular before it enters the medium is called the *angle of incidence*;

and the angle EQR which it makes after entering the medium is called the *angle of refraction*.

FIG. 1.

The law of refraction then is:

For one and the same medium, and the same ray of light, the ratio of the sine of the angle of incidence to that of the angle of refraction is a constant quantity for the same medium and the same ray.

This constant ratio is called the *index of refraction*. The law may be expressed in algebraic language as follows: Put

I, the angle of incidence;
R, the angle of refraction;
n, the index of refraction.

Then we shall have

$$n = \frac{\sin I}{\sin R}$$

or,

$$\sin R = \frac{\sin I}{n}$$

It is a law of the course of light that, if a ray passes in the opposite direction, say from R to Q, it will continue on the line QP after leaving the medium. It follows if the ray PQ emerges from the medium at R it will suffer refraction according to the same law as a ray entering it, but in the reverse direction. Hence if the lower surface of the medium is parallel to the upper surface, the emerging ray RS will be parallel to PQ.

One result of the above law is that a ray entering or leaving a medium in a direction perpendicular to the surface of the latter will undergo no refraction, but will continue in the same straight line. In this case the angles of incidence and refraction are both zero.

From the above equation we find that, if the angle R and the index of refraction are given, we can find the angle of emergence by the equation

$$\sin I = n \sin R.$$

Now, the angle R may be so large that this expression is greater than 1. Then there will be no possible value of the angle of emergence to fulfil the condition. It is found that, in this case, the ray will not emerge from the medium at all, but will be reflected from its inner surface as if the latter were polished and opaque. This is called *total reflection*, and is frequently applied in optical instruments. An example will show how this result may be

brought about. Let ABC, Fig. 2, be the section of a glass prism, the angle at C being a right angle. Let a ray enter the prism at the point Q in a direction perpendicular to the surface BC. It will then pass on and will reach the lower surface of the prism at the point R.

FIG. 2.

the angle DRQ will then be 45° . The sine of this angle is 0.707+

Now, a glance at the table which follows will show that in all sorts of glass the index of refraction is greater than 1.5. It follows that the sine of the angle at which the ray QR should emerge from the prism would be greater than 1.5×0.7 , and therefore greater than 1. There is then no possible angle to fulfil the conditions. The light is therefore reflected in the direction RS, as though the surface AB were perfectly opaque and highly polished.

Indices of Refraction of Various Substances.—Any one definite chemical compound has, at a given temperature, always the same index of refraction for the same ray. But glass is not such a compound, because its ingredients differ in different specimens of glass. It is impossible to make two pots of glass so exactly alike that they shall have the same index of refraction. It is owing to this fact that the idea frequently entertained, of making a telescope by putting together different pieces of glass, is impracticable. The following table

TABLE OF INDICES OF REFRACTION.

	Ray C	Ray D (mean)	Ray F
Soft crown glass.....	1.511910	1.514580	1.520994
Medium crown glass.....	1.513558	1.516149	1.522343
Hard crown glass.....	1.514571	1.517116	1.520994
Light flint glass.....	1.537682	1.541022	1.549125
Medium flint glass.....	1.575903	1.579880	1.589870
Dense flint glass.....	1.645773	1.651242	1.664981
Rock salt.....	1.54050	1.54418	1.55324
Iceland spar (ordinary ray).....	1.65435	1.65833	1.66780
Rock crystal (ordinary ray).....	1.5419	1.54424	1.54970
Fluor-spar.....	1.4339		
Canada balsam.....	1.528	1.53	
Diamond.....	2.417		
Ice.....	1.306		
Water.....	1.3307	1.3324	1.3366
Carbon disulphide.....	1.6240	1.6333	1.6584
Air.....	1.000290	1.000292	1.000294

shows the indices for a number of common transparent substances, and for three of the principal rays, C, D, F. It will be seen that glass has a greater refracting power than water;

and that plate glass is more refracting than crown. The diamond is the substance which has the greatest refracting power of all. It has also a great dispersive power; and it is owing to this fact that a diamond with polished faces shows so many brilliant colors when a ray of light falls upon it.

The refractive power of a substance is different at different temperatures. As a general rule, glass refracts more the colder it is. Consequently the focal length of a telescope will generally be slightly shorter the colder the weather. The difference is, however, slight and there are exceptions to the rule.

Refraction by the Atmosphere.—It will be seen by the preceding table that air has an appreciable, though slight, refracting power. It follows that a ray of light coming from a star is gradually bent toward the perpendicular as it approaches the surface of the earth. Only when a star is in the zenith does the ray suffer no refraction. The result is that astronomical observations upon the declination or altitude of a heavenly body require to be corrected for refraction. The latter, depending upon the density of the air, is greater the colder the air and the higher the barometer. Hence the astronomer has always to record the readings of his thermometer and barometer when he observes the altitude of a heavenly body. A rough approximation to the amount of the refraction can be made by the rule that at small zenith distances it is nearly $1''$ for each degree of zenith distance; and that, if the altitude is not greater than 45° , it increases nearly as the tangent of the zenith distance. The rate of increase is somewhat less than that given by this law, but still the refraction increases rapidly as we approach the horizon, where it usually amounts to about $35'$. This is greater than the diameter of the sun or moon. It follows that, when we see the lower limb of the sun just touching the horizon at sea, the luminary is actually entirely below the horizon. Moreover, the lower limb is elevated more by refraction than the upper one, with the result that a certain ellipticity is produced in the apparent outline of the sun, which is plainly perceptible to the naked eye.

A ray of light always suffers refraction when passing through the air in any other than a vertical direction, and its course is most curved when it is horizontal. In this case the curvature under ordinary conditions of the air is about one-sixth that of the earth. But this result depends entirely at the rate of increase or diminution of the temperature as we rise above the ground. If the air is very cold near the ground, and rises rapidly in temperature above it, a horizontal ray may be more curved than the earth, and strike the latter at some point. Objects may then be seen at such a distance that they are far below the horizon, as was once noticed by an Arctic navigator who, when separated from one of his ships, saw her image upside down above the horizon and, sailing toward it, found the ship. In the contrary case, when the air near the ground is much warmer than at a small height above it, the reverse effect is produced. A horizontal ray is then refracted upward so as not to strike the earth at all. It

is through this action that the mirages, so frequent in the desert and elsewhere, are produced. See **MIRAGE**.

SIMON NEWCOMB.

REFRIGERATION AND REFRIGERATING MACHINERY. Refrigeration is the operation of cooling substances by artificial means. Natural ice forms the greatest source of refrigeration, but there are certain conditions where cold produced through mechanical means possesses advantages over natural ice, which have led to the development of a number of refrigerating machines. The advantages of mechanical refrigeration over that produced by natural ice are that the temperatures of the objects cooled can be more readily regulated, lower temperatures can be obtained and in many cases the desired cooling effect can be secured at a lower cost. The industrial importance of mechanical refrigeration is of ever-increasing importance in modern life. One of its earliest and largest applications is to brewing. Moreover, it has revolutionized the industry which relates to the distribution and sale of ice. It has given us a product which is not only better than natural ice but can be sold at a price with which natural ice in many instances cannot compete. It has further created an enormous new industry in the transport and storage of the perishable necessities of life in a cold state. Broadly speaking, the methods that are employed for the production of cold may be classified under two heads, the second of which is by far the more important in practice. There is, first, the production of cold directly by the agency of heat, and, second, the production of cold by the expenditure of mechanical work. It is by the expenditure of mechanical work that nearly all modern refrigeration is carried out, namely, by compressing a gas or a vapor and afterward allowing it to expand under conditions which allow it to absorb heat from the thing that is to be cooled. To maintain the low temperature of a cold storage room or refrigerator space one must have a continual extraction of heat going on from a thing which is already colder than its surroundings. The same is true in the case of a brine tank for the production of ice. The brine has to be maintained at a temperature somewhat lower than that at which water freezes, considerably lower if the process of freezing is to go on at a reasonably fast rate. The heat which comes into the brine from the water to be frozen, the heat which the water gives out when it freezes and the heat which leaks in from all sources has to be continuously extracted from the brine at this comparatively low level of temperature. The heat so extracted is not destroyed but is raised to a higher level of temperature and is discharged by being given up to some substance which acts as a receiver of heat. In all actual cases of refrigeration the substance which absorbs the rejected heat is circulating water, which becomes more or less warmed by the heat which it takes up. The refrigerating machine accordingly works between two temperatures; the lower temperature is that at which heat is taken in from the body which is to be kept cold, and the higher temperature is that at which heat is rejected to the circulating water or other substance which absorbs it. In order

that this process may go on an expenditure of mechanical power is necessary.

Classification of Refrigerating Machines.—Refrigerating machines are generally classified by reference to the particular working substance they employ. A broad distinction may be drawn between machines which use air as their working substance, and those which use a liquid which is alternately vaporized and liquified during the cycle of operations. Generally speaking, in this second class of machines the liquid which is used is one whose vapor pressure is higher than the pressure of the atmosphere, under the actual conditions of temperature at which the machine works. If we take, for instance, ammonia or carbonic acid as the liquid which is alternately liquefied and vaporized, we find that under the conditions of temperature usually obtaining, the pressure of the vapor is higher than the atmospheric pressure. It is, however, quite possible to use a liquid which can only be vaporized by submitting it to a lower pressure than that of the atmosphere. Water is an instance in point. When water is the working substance, the whole action is taking place in what is, relatively speaking, a vacuum. It has to take place in chambers which are maintained at a pressure much below the pressure of the atmosphere, and consequently machines using water as their working substance are frequently spoken of, for this reason, as "vacuum" machines. Further, when a vaporized liquid is used for working substance one may either adopt simply mechanical compression as the means of restoring the vapor to the liquid state, or one may adopt a chemical action between the vapor and some other substance which has an affinity for it. This alternative gives rise to the grouping of machines under the title of "compression" machines on the one hand or "absorption" machines on the other. The latter are those in which a quasi-chemical action or species of solution goes on as a substitute for the mechanical compression used in other vapor machines. In absorption machines there is usually a direct application of heat instead of mechanical power. Machines of the vapor-compression type are further classified according to the particular vapor which they employ, as ammonia, carbonic acid, sulphurous acid or ether machines. Air machines are divided into two groups, in one of which the same volume of air is made to pass again and again through a cycle of operations without leaving the machine. Such machines are called closed cycle machines to distinguish them from those air machines in which air is discharged from and taken back again in the cycle at atmospheric pressure.

Air Machines.—Refrigeration machines which employ air as the working substance filled an important place in the development of mechanical refrigeration, and are still doing useful work; though the more efficient and more compact machines of the vapor-compression-type, using ammonia or carbonic acid, have now to a great extent driven them from the field. Dr. Gorrie of New Orleans invented an air machine in 1845. It had a compression cylinder in which the air was compressed, and from which it passed into a chamber which was kept cool by surrounding water. This chamber was maintained at a pressure of about 15 pounds per square inch above the pressure

of the atmosphere. The air was partly cooled during compression by the injection of water, so that what passed into the receiver was really air and water together. The air was further cooled in the chamber by the application of cold

FIG. 1.—Diagram of Open-cycle Air Machine.

C represents space which is to be kept cooled. Air is taken from it by compression cylinder M. It is then compressed from 1 to 4 atmospheres or so, and is discharged into the vessel A, where it is cooled by a circulation of cold water. The air is heated in compression, but the circulating water brings it down to a temperature only a little above that of the water itself. The air is next passed into an expansion cylinder N. During expansion it cools rapidly and reaches the cold room C at a very low temperature.

water outside, and then it passed on to another cylinder in which it was allowed to expand down to something like atmospheric pressure. While it was expanding it was mixed with a quantity of brine injected into the expansion cylinder. By expansion the air became much cooled and its low temperature was communicated by direct contact to the brine in the expansion cylinder. The air leaving the expansion cylinder was allowed to escape to the atmosphere, while the brine cooled to about 20° F. was conveyed into a tank and was usefully applied to ice-making or other refrigerating purposes. Many improvements were made in Gorrie's machine, which was followed in 1862 by Kirk's machine, an air machine of the closed cycle type. These types of machine and their successors are substantially the same. Their essential parts are a compression cylinder and an expansion cylinder. The first takes air from the room which is to be kept at a low temperature, compresses it; the air is then cooled by circulating water while compressed and is then returned to the cooled room by the expansion cylinder. Air machines have played a large part in developing the commercial applications of cold, although now the first place is taken by other types. Air can be employed as a medium for cooling itself more efficiently than it can be employed as a medium for cooling anything else. Also, air machines use a working substance that is simple and harmless and that costs nothing. For use on shipboard the air machine still retains the favor of some engineers although the more efficient vapor-compression machines dispute its sway even there.

Absorption Machines.—In machines of this type cold is produced as a direct result of the utilization of high-temperature heat, without the

intermediate step of converting the heat into mechanical work. In any machine of this type there are two substances used which have an affinity for one another so that one tends strongly to unite with or dissolve in the other when they are in the cold state, but they can be separated by applying heat. In the action of the machine they are alternately allowed to unite and made to separate. By the direct application of heat one of them is driven off in the form of a vapor. It is then condensed, is allowed to re-evaporate, and is absorbed by the other substance as soon as it does so. While re-evaporating it takes up heat from bodies round it, thus becoming effective for refrigeration. Of practical machines of the absorption type there are two kinds. In one kind the vapor used is water, and it is absorbed by sulphuric acid. In the other kind the vapor is ammonia, and it is absorbed by water. When water vapor is used, the pressure at which the vapor is formed must be very low, and hence machines using water and sulphuric acid are often described as vacuum machines. The method was known from about 1810 when Leslie described the process. In 1878 Windhausen made an improved machine of this type for the making of ice.

Ammonia absorption machines employ ammonia dissolved in water and are in much wider use than the sulphuric acid or vacuum machine. The action is in general respects the same, but as ammonia has a much higher vapor pressure than water, there is no vacuum, but pressure higher than the atmosphere throughout

FIG. 2.—Diagram of Cycle of Ammonia Absorption Machine.

The generator (top left) contains a solution of ammonia; heat is applied to it by a steam-coil. Ammonia gas passes over to the condenser, which is a coil kept cold by water circulation. Here the ammonia gas is condensed and is next passed through a valve into the evaporator or refrigerator. In evaporating there the ammonia absorbs heat from surrounding bodies, thus performing the work of a refrigerant. It is evaporated at low pressure and temperature. After re-evaporation the ammonia gas passes to the absorber where it is absorbed by water. This liquid is then pumped back to the generator where it goes in at the top, thus completing a cycle of operations.

the cycle. The ammonia absorption machine consisted merely of two vessels, in one of which was placed a strong solution of ammonia in water; the other in the first instance was empty, and was surrounded by cold water. The vessel containing the solution of ammonia was heated and the gas passed over under pressure into the other vessel, where it was condensed, giving up its latent heat to the water outside. Liquid anhydrous ammonia collected in the cold vessel while the solution in the first vessel became more and more dilute. After some time the source of heat was removed, and the vessel containing dilute solution was surrounded by cold water. The condensed ammonia in the other vessel then evaporated and

ber or cooler *F*, where it is evaporated through heat supplied by the coils contained therein through which a calcium chloride brine is circulated. The cold brine is circulated through the pipes *dd* to and from coils in the cold storage rooms. The ammonia gas leaves the cooler through the pipe *cc* and enters near the top of the absorber *J*, where it meets a spray of weak ammonia liquor, which is conducted to it through the pipe *ee*. The ammonia gas is taken up by the weak ammonia liquor in the absorber and forms the strong liquor which leaves the absorber through the pipe *ff* and is forced by the pump *K* through the pipe *ll*, the exchanger *L* and the pipe *mm* into the top of the generator, thus completing the cycle. Heat is given off by

FIG. 3.

was reabsorbed by the dilute solution. In re-evaporating, the ammonia exerted a refrigerating effect. This machine was intermittent in action but a continuous machine was soon developed from it by Reece, Stanley, Mart and others adding features which are found in the ammonia absorption machine of the present day. As has already been explained, the essential difference in an absorption machine and a compression machine consists in the method of increasing the pressure of the ammonia gas leaving the refrigerating coils. For the compressing pump and the steam-engine in the compression system there is substituted a vessel called an absorber, and a pump for pumping the liquid into a steam still. The condenser, liquid ammonia reservoir, expansion cock and cooler are the same in the two systems. A section of an absorption refrigerating machine is shown in Fig. 3. *A* is the still or generator in which the aqueous ammonia is heated in order to drive off the gas. The ammonia gas passes off through the pipe *aa* to the rectifier *B*, where the gas is cooled to a point where any water vapor in it will be condensed. The ammonia gas free from water vapor passes to the condenser *C*, where it is condensed and passes through the pipe *bb* to the ammonia reservoir *D*. From the reservoir *D* the liquid ammonia passes through the valve, or expansion-cock *E*, into a refrigerating cham-

ber or cooler *F*, where it is evaporated through heat supplied by the coils contained therein through which a calcium chloride brine is circulated. The cold brine is circulated through the pipes *dd* to and from coils in the cold storage rooms. The ammonia gas leaves the cooler through the pipe *cc* and enters near the top of the absorber *J*, where it meets a spray of weak ammonia liquor, which is conducted to it through the pipe *ee*. The ammonia gas is taken up by the weak ammonia liquor in the absorber and forms the strong liquor which leaves the absorber through the pipe *ff* and is forced by the pump *K* through the pipe *ll*, the exchanger *L* and the pipe *mm* into the top of the generator, thus completing the cycle. Heat is given off by the ammonia on absorption, which is taken up by water circulated through coils contained in the absorber. The exchanger *L* saves heat which would otherwise be lost, and thus increases the efficiency of the machine. The weak liquor on leaving the generator is at the highest temperature at which the aqueous ammonia is brought in the system, whereas the strong liquor leaving the absorber is at the lowest temperature. It is necessary to cool the weak liquor before it enters the absorber and to heat the strong liquor to the temperature of the generator, and this is accomplished, in part, by the exchanger by making the weak liquor heat the strong liquor and the strong liquor cool the weak liquor. The weak liquor at about 270° F. is taken off near the bottom of the generator and passes through the pipe *nn* to the top of the exchanger *L* and thence through a coil contained therein. From the bottom of the exchanger it passes through the pipe *ee* to the absorber *J*. The strong liquor at about 130° F. passes through the exchanger *L* in the reverse direction to that of the weak liquor, and the interchanging of heat is such that the weak liquor leaves the exchanger say 100° F. cooler than it entered and the strong liquor is heated a corresponding amount. The strong liquor is made to enter the top of the generator and pass through what is called an analyzer *M*. The

analyzer adds to the efficiency of the generator by causing the strong liquor to meet the outgoing gas generated at the bottom of the still. An exchange of heat takes place, which causes much of the ammonia contained in the strong liquor to be driven off at a lower temperature than that which exists at the lower part of the still and produces ammonia gas more free from water vapor than could be secured if the strong liquor were introduced into the lower part of the still. The cooling water passes first through the condenser *C*, entering through the pipe *oo* and from thence to the absorber *I* through the pipe *pp*. It finally leaves the absorber through the pipe *qq*. Heat is supplied to the generator by means of steam which enters a coil contained

denser through the pipe *bb* to the liquid ammonia reservoir *D*. From the reservoir *D* the liquid ammonia passes through the valve *E*, termed "the expansion cock," where it is reduced in pressure from say 140 pounds per square inch above the atmosphere to a pressure of say 15 pounds per square inch above the atmosphere, and thereby is reduced in temperature from about 80° F. to about 0° F. The anhydrous ammonia at a temperature of about 0° F. flows in coils of pipe in the brine cooling tank *F*, and abstracts heat from the brine by being evaporated. The gas produced by the evaporation of the ammonia passes from the condenser coils through the pipe *cc* to the compressing cylinder *A*, where it is again com-

FIG. 4.

therein through the pipe *rr*. The water vapor condensed in the rectifier together with the ammonia which it carries with it is returned to the analyzer by means of the pipe *ss*. The drip water from the generator coil is discharged through the steam trap *N*.

Comparison of Ammonia Compression and Absorption Systems.—Tests have shown that the economy of a compression system when driven by an engine requiring three pounds of coal per hour per indicated horse power is about equal to that of the best absorption system when used in connection with a boiler of good efficiency provided the suction pressure of the ammonia gas is about 20 pounds per square inch above the atmosphere—that is when the temperature of the substance to be refrigerated is about 20° F. For higher temperatures and higher suction pressures the compression machine is more economical in fuel, and for lower temperatures the absorption machine is more economical, unless the compression system employs a multiple expansion engine so as to reduce the coal consumption below the three pounds on which this comparison is based.

Ammonia Compression Machines with Brine Circulation.—Fig. 4 shows a compression system for a cold storage warehouse. *A* is the compressing cylinder which is driven by the steam engine *B*. The gas on being compressed in *A* passes up through the pipe *aa* to the condenser *C*, where it is liquefied. The liquid anhydrous ammonia passes from the con-

pressed and returned to the condenser. The brine which is reduced in temperature in the cooler *F* is pumped by means of the pump *G* through the pipes *dd*, which are connected with coils *HH* in the cooling rooms *II*. After the brine has passed through the cooling coils it is returned to the cooler *F*. In passing through the expansion cock *E* about 10 per cent of the weight of the anhydrous ammonia will be vaporized and it is the heat required to produce this vaporization that causes the liquid to be reduced in temperature from say 80° F. before throttling to 0° F. after throttling. Ninety per cent of the ammonia is, therefore, in the liquid state when it has attained the temperature of ebullition corresponding to the pressure existing in the cooler. The brine in the cooler is at a slightly higher temperature than the liquid ammonia contained in the coils and transmits heat to it so as to boil it and convert it into gas. The brine in parting with its heat is thus cooled to the extent of the heat required to evaporate 90 per cent of the liquid ammonia which passes through the throttling cock. In some types of compression machines all of the ammonia is not allowed to vaporize in the cooler, whereas in other systems care is taken to secure a complete evaporation. This gives rise to two classes of machines, one of which is known as the wet or cold compression and the other as the dry compression system. The brine returns to the cooling tank after passing through the storage rooms at about 6° higher

temperature than that at which it leaves the cooler and the mean temperature of the brine is about 10° higher than the boiling point of the ammonia corresponding to the suction-pressure. The mean temperature of the brine is 6° less than that of the air in the storage-rooms. For the storage of beer a temperature of about 36° F. is required, and this is secured with a pressure of about 28 pounds per square inch above the atmosphere in the coils of the cooler. Slaughter-houses require about 25° F. in their storage-rooms, which must be obtained by a pressure of about 22 pounds per square inch in the cooler. The storage of fish requires a temperature of about 0° F., for which a pressure in the brine coils of the cooler of about five pounds per square inch above the atmosphere must be used. Instead of a brine made with ordinary salt one formed from chloride of calcium is often used as a circulating medium because it produces less corrosion in the pipes than salt brine and may be brought to a lower temperature before it freezes or becomes partly congealed. In another system air is blown around the coils of the cooler and is circulated through the storage-rooms, and a chamber freshly filled with material can be more quickly cooled than by the use of cooling coils. The air system appears to be more expensive to operate than the brine system.

Direct Expansion Systems.—In some machines instead of expanding the ammonia in coils placed in the cooler and forcing cold brine through the coils in the refrigerating-rooms the anhydrous ammonia is expanded directly in coils placed in the refrigerating-rooms. In this system we eliminate the loss due to the difference in temperature between the brine and the coils in the cooler. The use of brine is, however, regarded by many as a safeguard against damage to the material in the storeroom by the accidental escape of ammonia from the circulating pipes; the brine circulation is for this reason much used, notwithstanding the fact that the cost of the piping is less for the direct expansion system and that there is a saving in the cost of operation. This saving is due to dispensing with the brine circulating pump and permitting from five to 10 pounds higher pressure to be used in the coils of the cooler. In the wet system of compression, known also as the Linde system, the presence of liquid ammonia in the compression cylinder limits the highest temperature attained by the ammonia during compression to the boiling point of the ammonia liquid corresponding to the highest pressure, or say to 80° F. With the dry system of compression the maximum temperature in the compression cylinder is about 100° F. higher than this, and if the cylinders were non-conductors of heat the wet process would be more economical than the dry. It appears by tests, however, that the influence of the conductivity of the cylinder walls in abstracting heat in one part of the cycle and giving it back in part in another, makes the two systems about equal in economy.

Other Compression Systems.—Water, sulphuric ether, sulphur dioxide, carbonic acid, methylic ether and certain petroleum products may be used in compression systems in the same way as ammonia. In the case of water temperatures colder than 32° F. require a suction pres-

sure of within .08 pound per square inch or 0.16 of mercury of a perfect vacuum. The dimensions of a compressor cylinder of such a plant is about 150 times that for ammonia. The use of water as a working fluid is, therefore, impracticable except for the production of ice as described under section *Ice-making*. Sulphuric ether was the first substance practically applied to refrigeration by the compression system. The volume of the compressing cylinder is, however, about 17 times that required for ammonia, and its use has, therefore, been abandoned. Sulphur dioxide machines produce a temperature of about 5° F. in the cooler with a suction of about three pounds below, and a condenser-pressure about 35 pounds per square inch above the atmosphere. Their economy is about the same as with ammonia, but the compressing cylinder must be about three times as large as for ammonia. The Pictet system uses sulphur dioxide, and in some cases what is called the Pictet fluid, which is sulphur dioxide mingled with about 3 per cent of carbonic acid. Carbonic acid gives a temperature of 5° F. in the cooler with a suction-pressure of about 330 pounds per square inch above the atmosphere and a condenser pressure of about 900 pounds per square inch. The fuel required is more than with ammonia, but the size of the compressor cylinder is about one-fourth that required for ammonia. Carbonic acid is used only to a limited extent; but the compactness of the machine employing it, together with the fact that any bursting of a pipe or leakage will not lead to the same disastrous results as with ammonia, renders it more suitable for service on ships and also in some other special lines of work. Nothing definite is known of the economy of the few machines which have used methylic ether and petroleum products. From the physical properties of these substances it would appear that they would give about the same economy as ammonia or sulphur dioxide.

Ice-Making.—The production of artificial ice. The heat is usually abstracted from the water to be frozen by evaporating a volatile liquid, such as ammonia, sulphur dioxide or ether, which in evaporation absorbs heat. Anhydrous ammonia is most commonly employed. This boils at 27° F. below zero at atmospheric pressure. If the anhydrous liquid ammonia is introduced in a coil of pipe which is placed in a tank of brine it will absorb heat from the brine during the process of boiling equal to the latent heat of evaporation. If a can of water is immersed in the brine it will in turn be cooled and then frozen, and this process constitutes the elements of the Can System of ice making. If on the other hand, the ammonia in the coil is made to cool a flat plate forming the vertical side of a water reservoir ice will be formed directly on the plate, and this constitutes the elements of the Plate System of ice making. The vapor produced when the liquid ammonia evaporates in the coil is, in all cases, again converted to the liquid state so that it may be used over again. In abstracting heat from the refrigerating coil the vapor is at a low pressure, say 15 pounds per square inch above the atmosphere at which the boiling point of the liquid is 0° F. To convert it to a liquid it must be raised in pressure, to say 140 pounds per square inch above the atmosphere, at which

the boiling point of the liquid is 80° F. As the temperature at the boiling point of a vapor is the same as that at the condensing point, the vapor at 140 pounds pressure can be condensed by cooling it to 80° F., and after such condensation it may be returned to the refrigerating coils and used over again for abstracting heat from the brine. To raise the pressure of the gas from 15 pounds to 140 pounds per square inch we may employ either of two methods—compress it by means of an engine, or we may absorb the vapor in cold water and then heat the aqueous solution of ammonia in a still, and so drive the gas off at high pressure. These two methods of compression constitute the distinguishing features of what is called the compression and absorption systems of ammonia refrigerating machines.
